On comparing the experiments of these two chemists, it will, we think, be at once obvious, that the more operose and violent operations of the former produced new compounds; and, in confirmation of this idea, we must remark, that in every ingredient obtained by M. Fourcroy, animal matter was conspicuous: we have carefully pointed out its appearance in each. We may, therefore, safely conclude, that the animal oxide is the chief ingredient of the calculus, and that its component parts are the principles already described from the *Annales du Museum National*.

We should not, perhaps, wholly pass over the concretions of other animals; yet, not to distract the attention, we shall finish the subject of human calculi.

Notwithstanding the labour of the chemist, we are almost equally at a loss respecting the source of calculi, and what has been styled the diathesis calculosa. It is not hereditary: it is not acquired. No constitution is peculiarly subject to it; yet we think the fair complexions, with light hair and blue eyes, have been the most common victims. This may be fanciful; for if one of ten has been of this description, let it be recollected that not one of a million of this description has suffered from calculus. The remote causes, usually assigned, are equally without foundation. Hard water is certainly not a cause, for selenite is not an ingredient in calculi: wine does not occasion it, for the calculus does not

resemble tartar. Cyder is equally harmless; and beer has been accused, only because, as a more general beverage, an unusual proportion of beer drinkers must be affected. It has been said, and generally believed, that a nucleus was only required to form a stone from the depositions of the urine; but gravel almost constantly occurs in the bladders of many persons, and yet no stone is formed. In short, it is one of those arcana which, after all our investigations, must still remain such. We know that our glass falls to the ground from gravity; and, though we know not the cause of gravity, we can, however, preserve it. We know not the source of calculi, but we can often mitigate their symptoms; relieve, perhaps, in some, though very rare, instances cure. If chemistry, however, does not assist us, we may perhaps draw some useful hints from analogy.

The connection of calculus with gout is well known; and the latter is certainly in a great degree depending on a weakened or disordered stomach. If animal matter is formed, but in a state not adapted for nutrition, it must be carried out of the body as an injurious substance, and it may be deposited on the kidneys or joints. We shall here be accused of inconsistency, and told that we are supporting the doctrine of morbid matter as a cause of gout. It is not, however, the cause, but the effect of the cause; in reality, the first in the chain of effects or symptoms. In the constitution that has long suffered from the gout, it seems to be determined to the kidneys with the phosphoric acid retained in the early period of the paroxysm; and its concretion is assisted by the long confinement on the back, which the pain of gout often demands. In relaxed constitutions of the scrofulous kind, it may also be occasionally deposited in different parts, though the kidneys seem to yield it the most ready outlet. This appears to us a step, at least, towards the explanation of the cause. If fanciful, or unfounded, it has detained the reader only for a very short time.

The calculous diathesis is so imperfectly known, and calculus of the bladder so rare a disease, that little has been attempted to prevent it. As stone, however, when once extracted, will sometimes recur, preventives, at that time, should be employed. In this class, general tonics will be found useful; and if there is any whose action is more particularly directed to the kidneys, these should be preferred. The *uva ursi* has been supposed to have this effect, and it may be employed with the decoction of the bark: at the same time, a mild diet, with every plan that will dilute the urine, without stimulating the urinary vessels. The free use of watery fluids; some of the diuretic vegetables; fruit, of which *Linnaeus* seems to prefer strawberries; are proper, though with an admixture of mild animal food. The acidulous soda water will be an useful drink. If the danger is apparently more urgent, the use of the bitters may be occasionally intermitted; and soap, with lime water, given for six weeks or two months, when the bitters may be again resumed. The patient should never suffer the urine to stagnate, but use himself to discharge it at stated times in the day and night, which will soon bring on the habit of doing so, whatever the quantity in the bladder may be. This, however, must not be too often practised. Once in the

night, and three times in the course of the day, at least, the discharge should be encouraged. If his life is a sedentary one, it should be more frequent.

A calculus, however, at last shows itself by symptoms somewhat equivocal, differing, however, according to its seat. Gravelly concretions in the kidneys, which seem to consist almost exclusively of the uric acid, we must consider under the article *NEPHRITIS*; and a stone occurring in the ureter cannot be easily mistaken. Acrid matter in the urine, a coagulum of blood, or gluten, will sometimes occasion violent pain, which will be mistaken for a fit of stone, and nothing can ascertain the complaint but the catheter, unless the offending cause should be discharged. An abscess of the prostate, or in the rectum, pressing on the bladder, has been said also to imitate the pain of a calculus; yet, as these are easily ascertained by an examination per rectum, the error can neither be long continued nor dangerous.

When a calculus exists in the bladder, it produces pain chiefly by paroxysms. There are intervals, often long ones, of the most perfect ease, but the paroxysms are extremely severe. These are relieved by emollient oily clysters, followed by opiates in the form of clyster, and by the mouth; the doses of which must be such as to meet the pain, whatever quantity may be required. We may notice, in this place, that the proportion of opium which is employed in relieving the pain, has no effect on the constitution in general; it is the excess of this dose which is felt.

The disease, however, remains; and it must then be considered whether the operation should be hazarded, or the solution of the stone attempted by internal medicines. The operation, though severe, is not peculiarly dangerous; yet, to attempt it on exhausted arthritic constitutions would be highly improper: if firm, no period of life is an obstacle. Another consideration must, however, stop us. We do not remove by the operation the disposition to form stone; and the disease has been known to recur. It does not, however, always return; and, within our observation, it has not returned in the greater number of instances. We remember an observation of Mr. Justamond, that the operation does not succeed if the patient has previously used lithontriptics. But this we have not found supported by experience. If, therefore, the constitution of the calculous patient is firm, if the paroxysms are frequent and severe, if lithontriptics are not found in three or four months to greatly relieve, the operation is advisable. See *LITHOTOMY*.

Many, however, will not submit; and, in all, we think lithontriptics should be tried; for, though we have no decisive evidence of their dissolving stone, they greatly mitigate the pain, render the paroxysms more distant, as well as more mild. It has been seen from the experiments of *Fourcroy*, that almost every ingredient in calculi is dissolved by the caustic alkali; and various experiments have shown that the whole calculus yields to its powers. Lime water has been found also a solvent of calculus out of the body; and on these our hopes have chiefly rested. It is obvious, however, that what is taken by the mouth, has not only a circuitous route to reach the bladder, but is subject to many chemical changes; nor, indeed, are there many well-

authenticated facts of the urine being so changed, as to become a menstruum for the stone. Almost the only instance, except the case of Dr. Newcombe, recorded by Dr. Whytt, is that of Mr. Holme. Yet, though it may not be so accumulated in the urine as to render it an active solvent, it may destroy the animal oxide in it, or prevent its tendency to concretion; and it may have sufficient powers to soften the surface of the stone so as to lessen the irritation, and, of course, the spasmodic symptoms, which are its consequence. It is, we believe, an incontrovertible fact, that, where the stone has been unchanged, the paroxysms of pain have been greatly mitigated; and, to lessen pains so violently excruciating, is surely an object of no little importance.

Lime was long known as a solvent of stone, and different methods were employed to administer it with safety. One of these plans fell into the hands of Mrs. Joanna Steevens, daughter of a gentleman of a respectable family in Berkshire, and her success occasioned a considerable anxiety to discover the secret. At last, parliament bought it for 5000*l.* after different trials had been made of it with advantage. In many instances, stones, which had been sensibly felt, were no longer to be discovered; and, as the *same* persons were examined by surgeons, men of the greatest skill and eminence, both before and after the exhibition of the medicines, it is fair to conclude that in some instances they were dissolved, though we have recorded the singular mode which, in one case, occasioned the deception. Mrs. Steevens, it is said, first gave the calcined egg-shells only, but finding these produce costiveness, she added soap. In time she rendered her process more complicated, adding snails burnt to blackness, a decoction of camomile flowers, parsley, sweet fennel, and the greater burdock. When we consider the effects of bitters, we shall not perhaps think, with Dr. Hartley, these additions to have been wholly useless. It is singular, however, that the egg shells, though calcined, were exposed to the air till reduced to a fine powder. No one seems to have carefully examined them in this state; and it is only presumed that they retained some portion of the caustic acrimony. Various other ingredients were confessedly used as disguises.

As soap was with reason supposed to add considerably to the virtues of the lime, it led to the use of the caustic alkali, softened by a more pleasing mucilage, veal broth. Since that time it has been used alone.

The following is the best mode of preparing and administering it:

Take of kali prepared, eight ounces; of fresh quicklime, four ounces; of distilled water, a quart: mix them well together in a large bottle, and let them stand for twenty-four hours; then pour off the ley, filter it through paper, and keep it in well stopped phials for use. Of this the dose is from thirty drops to two drachms, which is to be repeated two or three times in a day. Mix the quantity to be used in the day with three pints of plain broth, which has been made with the lean part of veal, all the fat or oily parts being separated from it, by putting it, when made, into a large bowl, and skimming them off with a spoon when cold, and let the patient drink within an hour a pint of this broth three times a day, early in the morning, at noon, and in the evening: continue the use for three, four,

or more months, living during this course on such things as least counteract the course of this medicine.

Various other lithontriptics have been employed; but the calculus seems a more uniform concretion than has been supposed, particularly by Dr. Dawson in the London Medical Transactions, vol. ii. p. 105. The common fixed alkali, or, in stricter language, the carbonated alkali, has been employed; and, more lately, the alkaline carbonated water, viz. the alkali with an excess of carbonic acid. Some cases have been related, in which this remedy has been employed with success, and we may easily find a foundation for its use.

Honey has been used also with success; and Mr. Home, surgeon at the Savoy, has recorded its utility in his own and his father's cases. It was an ingredient in Mrs. Steevens' farrago, but in too small a proportion to be of advantage. Bitters have been also employed, and we have already mentioned their use as preventives: we have reason to think that they may be serviceable in mitigating and protracting a fit. When we reflect on these different means, we shall perhaps find only the pure alkali and the lime water adapted for the solution of the calculus; and, when the circuitous course of each is considered, we may suspect that they seldom reach the bladder without impaired virtues. We have, indeed, two instances in opposition; but, without offence to either, may we not suspect a little predilection in favour of the remedy to have influenced the observation? It once happened in a clinical ward, that the urine was reported to effervesce with alkalis. Some of the elder students, in private, suggested that they could perceive no effervescence but the slight separation of air, occasioned by the mixture of any two fluids. On the next day it was reported that no effervescence *had* taken place, nor could it, adds the professor, for the alkali was caustic. What adds to our scepticism on this subject is, that from the use of lithontriptics the symptoms have been often relieved, though the stone has remained without any change.

When we reflect on the connection of stone with gout, on the weakness of the stomach, apparently the origin of each, and the utility of bitters, stimulants, and antacids, we own that we rest with more confidence on the idea of the whole originating in imperfect digestion, and the production of an animal oxide not admitting of application as a nutritious substance. But, whatever becomes of the theory, lime water and soap, acidulous soda water, caustic alkali, or bitters, are highly useful. Of the soap as much must be taken as the stomach will bear, or as much as will prove gently laxative; but of the lime water few can take more than a pint daily. The acidulous soda water may perhaps be taken in larger quantities, as it is more agreeable; and the acidulous salt is now prepared, so as to produce this water extemporaneously. It must, however, be swallowed while dissolving, as the carbonic acid gas rapidly escapes. Of the liquid caustic alkali, from thirty to a hundred and twenty drops may be taken in veal broth two or three times a day.

The inconveniences arising from the use of large quantities of soap and lime water are, impaired digestion, and, consequently, debility and emaciation. With the superfluous, the necessary acid seem to be destroyed. This effect has not, however, followed the soda with an

excess of carbonic acid; though the bitters are suspected, by long continuance, of diminishing the tone they were intended to preserve. Generally speaking, therefore, these remedies should not be continued long without intermission: yet they will not soon produce a change; and a trial of three months is at least necessary. If no benefit is then obtained, they should be relinquished or changed. If any amelioration of the symptoms should be observed, they may be pursued longer; yet in no case, probably, beyond nine or twelve months, without some intermission, or interposing a warm tonic for a few weeks. As the management during the paroxysm has much engaged the attention of physicians, we shall add the outlines of what has been directed.

During a fit, if the habit is plethoric and sanguine, *bleeding* both guards against and removes inflammation. Those persons who are subject to regular returns, may lose blood a little before the expected period.

*Diuretics* should never be of the stimulant kind; the emollient and oily are the most proper; and after these, the diluents should be freely employed. In general, the more painful the fit, the gentler should be the diuretics, and the less copiously given. The aged and weak should be allowed the use of cordials with their diuretic medicines. When the pain and spasms are very violent, and yet there is hope that the stone will pass the urinary ducts, gentle diuretics, mixed with mild anodynes, do the greatest service: for the latter relax the parts and ease the pain, and the former more easily and safely propel the stone. When gravelly matter hath been seen to be discharged with the urine, and to subside presently after it is made, light steel waters, either of the purging or of the diuretic kind, very safely and effectually expel it, and strengthen the kidneys: the water should be continued some weeks, and repeated at proper intervals. But if a stone in the kidneys is so large that there are little hopes of its passing through the ureters, which is known from the continuance of the disease, the steel waters should not be used.

Of all the *purging* medicines the oleum ricini is to be preferred in *calculous* disorders; whether a stone, or other cause of inflammation, produces gravelly symptoms. To relax the passage for the calculus to pass from the kidneys to the bladder, this oil is preferable to any other known medicines, either by the mouth or clyster. Oil, manna with nitre, or vitriolated magnesia with the oil of almonds, may be used in its stead; for they empty the intestines, take off all pressure upon the ureters, moderate the heat of the body, lessen the inflammation, and relax the spasm which the pain occasions. If the ol. ricini is taken in the fit, so as to keep the belly lax, and the aqua kali puri at proper intervals, mixed in any suitable vehicle, *their efficacy in calculous disorders will equal that of the most boasted remedies used in these cases.* In slighter attacks, a mixture of soap four parts, and rhubarb one part, twice a day, in doses sufficient for keeping the bowels easy, will be sufficient.

The use of *clysters* is singularly beneficial. The colon forms an arch over both the kidneys, is sometimes joined to the left; and, consequently, a warm emollient decoction thrown up, may, by its heat and moist vapour, relax and soften the kidney like a fomentation.

Hence we see why flatulent or other accumulations usually occasion a fresh fit; and why the left kidney is more subject to complaints than the right. The ol. ricini is peculiarly useful in emollient clysters; but turpentine should make no part of their composition. Two drachms of the tinctura opii may be thrown up, after the operation of the laxative clyster, when the pain is great.

When the vomiting abates, the stomach and bowels are freed from their contents; then it is proper to give opiates, which, by easing the pain, and relaxing the spasm, most effectually open a passage. Their repetition can only be determined by the attending physician. When the pain is of very long continuance, and accompanied with great prostration of strength, especially if these occur in advanced age, and with a weak state of the pulse, Hoffman forbids the use of opiates, as of a poison; and says that, in such cases, gentle cordial waters, as those of mint, balm, and cinnamon, with the addition of a few grains of saffron, and the moderate use of wine, are the best means of supporting nature. Yet, if the loss of strength is caused by the violence of the pain alone, opiates will be necessary.

The SEMICUPIUM is an useful assistant when the pain is violent, for it powerfully relieves the stricture of the part. After sitting a sufficient time in it, ten or twenty of the soap pills may be taken.

*Vomiting* is sometimes a troublesome symptom; but if not very severe, it is rather useful, and ought not to be suddenly checked. Whilst moderate, it rather prevents the cohesion of the gravel, and promotes its expulsion. When it is necessary to remedy this complaint, the patient may drink freely of some warm aqueous liquor to unload the stomach of its contents; and the saline draught in the act of fermentation, followed by an opiate, may be given.

If a stone stick in the kidney, or the ureter, stimulating medicines are unsafe, and diluents are thrown up without producing any advantage; but when the anodynes have considerably abated the spasms, when the pulse is grown calm and soft, and the whole body is of a moist and equal heat, then the expulsion of the stone or gravel may be expected, often without further assistance.

*Bloody urine* is sometimes a symptom attending the gravel, in which case a dose of manna may be taken as a purge, in a quart of milk whey, at several draughts. (See Wallis's Sydenham.) To quicken its operation, and render it easier in the stomach, a slice of lemon may now and then be sucked. This may be repeated every day, or every other day, for it both eases the pain and moderates the discharge of blood. After its operation, a dose of opium may be taken at bed time. If the bloody urine is from the bladder, and attended with spasms there, or an ulcer, warm external applications are useful just above the pubes.

When CALCULOUS COMPLAINTS ATTEND DURING PREGNANCY, which very seldom happens if the pain is violent, a slight bleeding may be admitted, with oily laxatives, and afterwards opiates. If a stone is perceived in the bladder, it should be extracted before pregnancy; but if the woman is already pregnant, we should wait until her delivery. During the time of labour, the stone should be pushed and kept up above the child's head, if possible; if this cannot be done, the assistant

must pass up his hand as soon as the os internum is sufficiently dilated, and, breaking the membranes, turn the child, and bring it away by the feet. There will then be room for the stone to be raised by the catheter, to prevent the child's head from pressing it against the urethra, which would give the woman great pain, and perhaps lacerate the parts.

See Boerhaave, Aretæus, Alexander Trallian, Lommius, Hoffinan, Wallis's Sydenham. Lobb on the Stone and Gout. Medical Museum, vol. i. and iii. Bell's Surgery, vol. ii. 9, &c. White's Surgery, 348. Memoirs of the Medical Society, vol. i. 225.

A stone is sometimes forced from the bladder into the urethra, and sometimes it is generated in this passage. Boerhaave observes, that if recent urine be placed in a heat no greater than that of a healthy man, it soon throws off a stony matter to the sides of the vessels; a calculous matter, by too long a detention of this fluid in the bladder, may therefore be soon and easily formed; and a little of it may on its passage with the urine be so entangled in the urethra, as not readily to be extricated, but become the basis of a larger stone. Mr. Warner observes, that the urethra, in cases of this kind, becomes a cyst, which acquires a great degree of hardness, remaining compact and whole till an inflammation is produced by its no longer admitting any further distention. The inflammation is then soon communicated to the teguments, by which means they become painfully tender, and are easily lacerated.

If a stone is obstructed in its passage through the urethra after bleeding, an emollient clyster and an anodyne draught will be proper; common emulsion should be drunk freely, and if the patient is placed in a warm bath presently after the clyster is administered, the stone often escapes.

If the stone stick in the neck of the bladder, and require an operation for its extraction, introduce two fingers into the anus, to detain the stone until the incision is made through the perinæum upon it. After the operation, as well as for some days before, Heister advises the patient to drink as sparingly as possible, that the wound may not be irritated by the urine. To guard against this inconvenience, a canula may be introduced beyond the wound, and kept in the urethra until it is healed. In whatever part the stone is lodged, the incision must be made in the course of the urethra, and the wound in the skin parallel to that in the urethra. When the stone is extracted, close the wound, and keep its lips together, by first laying on it a pledget of lint spread with some digestive ointment, then secured with slips of plaster, as directed for the dry suture.

It has been lately recommended to inject the caustic alkali into the bladder, diluted in any mucilaginous fluid; and experiments have been adduced to show, that the bladder can bear, without inconvenience, a sufficient quantity to render the urine an active solvent of calculus. On this subject, however, we would lay down no precise rule; for the bladder differs greatly in irritability in different persons, and it will be proper to begin with a small proportion. The plan is too obviously useful to be neglected, and experience may enable us to give a further account of its success in some future article. We may add, however, in this place, that weak vinegar, which may with safety be injected into the bladder of a horse, is found, from the experiments of

Vauquelin and Fourcroy, an effectual solvent for the calculus of that animal.

We shall conclude this article with some comparative remarks on the human and animal calculi, from a second Memoir of M. Fourcroy, in a subsequent volume of the Annals of the National Museum, and with an analysis of the other human calculi.

The difference between the human urinary calculus, and those of other domestic animals, is truly singular. The renal and vesical calculi of the horse, the ox, the hog, and even of the rat and rabbit, in whom calculi are frequently found, consist only of carbonate of lime, connected by an animal gluten. Once M. Vauquelin suspected that he discovered the uric acid in the calculus of a tortoise, but it was not in sufficient proportion to render it certain. M. Fourcroy and his associates constantly found a striking analogy between the nature of the urine, and that of the calculus of the domestic mammalia. But, though the urine of horses does not contain phosphat of lime, they found it in the sweat, when dried on the hair; and, from Mr. Hatchet's experiments, it will appear that nature is uniform in her productions. The same substances are formed in the animal economy, deposited only on different organs.

Many of the bezoars of different forms and colours chiefly consist of calcareous phosphat, but they seldom contain the acid phosphat, and are consequently formed in the intestines; which is sufficiently proved by their nuclei, which are often the kernels of fruit, and sometimes small branches. In these animals, therefore, the substance, not carried to the kidneys, concretes in the intestines.

In the domestic animals, and those wild ones confined to the menageries, intestinal concretions, from the size of a large hen's egg to that of an ostrich, are often found in the cæcum. Those in the horse are of a greyish colour, formed of prismatic radii, without any distinct strata: the surface consists of irregular crystals worn down by attrition, with cavities between them. All these bezoars are composed of an ammoniaco magnesian phosphat, a substance lately discovered in barley and oats, as well as in some of the legumina, though in a less proportion. We thus find the source of these concretions; and their nuclei are generally some undigested seed, or a bit of straw. This salt does not naturally concrete in man; and it requires some additional substance or circumstance to assist its appearance, when it is discovered in the calculi of the kidneys and bladder. Nor is it easy to say, why some of the bezoars of wild animals should consist of the ammoniaco magnesian phosphat, while others contain the phosphat of lime only.

Dr. Pearson has analysed also the calculi of many animals. That of a dog was found, by him, to contain phosphat of lime and ammonia, with some animal matter: that of a rabbit yielded chiefly carbonate of lime, with common animal gluten, and perhaps a small proportion of phosphoric, but no uric acid: those of horses, whether vesical or intestinal, afforded phosphat of lime and ammonia, with animal matter, which melted like super phosphat of lime, after separating the animal substance and ammonia by burning. A large quantity of matter found in the bladders of horses not crystallized, each of several pounds weight, was carbonate of lime with the animal fluid. Bertholdi found

the calculus of a pig, which was nearly twice as heavy as distilled water, to consist of phosphat of lime.

*Arthritic calculi* were once supposed to be chalk, then to resemble the earth of bones; to be insoluble in acids, to be soluble in them, or to be soluble only in the nitrous acid. Various other discordant opinions were entertained, till Dr. Woolaston, in the Philosophical Transactions for 1797, gave us more distinct ideas on the subject: he found them to consist of the lithic acid and soda. We thus find the foundation of the use of antacids, and perhaps of bitters, in cases of gout.

The *calculi of the pineal gland* were supposed by many authors to be imaginary. Sabulous concretions, however, in this part have been often discovered; and Dr. Woolaston, by a delicate chemical test, has discovered them to consist of phosphorated lime. This is, however, a refinement only, for these concretions are not connected with any concurrence of symptoms so as to form a disease.

The *calculi of the prostate gland* also consist, according to Dr. Woolaston, of phosphorated lime.

*Calculi of the salivary glands, calculous incrustations on the teeth, ossifications in the larger vessels of the heart, between the muscles, in the corpora cavernosa penis, and in the pancreas, resemble the earth of bones.* Those of the *bronchial glands* we have found to be similar: those from the uterus have not been examined. See Heister's Surgery, Warner's Cases in Surgery, Gooch's Treatise on Wounds, and the Med. Mus. vol. i. and ii. Bell's Surgery, vol. ii. 9, &c. Baillie's Morbid Anatomy. Woolaston's Phil. Trans. 1797. Pearson's Phil. Trans. 1798. Annales de Chimie, xvi. 63. xxiii. 123. xxviii. 52. xxx. 57. xxxii. 185, 213.

CALCULUS BILIA' RIS, (from *bilis, bile*). GALL STONE.

Though we have spoken of these stones at sufficient length, yet some facts, chiefly of a chemical nature, remain. Biliary calculi are divided by Walker into the striated, lamellated, and cortical; and by Vicq. d'Azyr into those which consist of a yellowish bilious matter, whether filamentous or not; those composed of crystalline matter of different degrees of lustre, with or without a covering, and into calculi consisting of both substances. Externally they are usually laminated; internally, radiated: the greater number have no taste, but many are intensely bitter. From their chemical properties they are divided into two species; those consisting of a shining, foliated, crystalline substance, analogous to spermaceti, and those which resemble inspissated bile, in which the former seems to have crystallized. In every instance, the crystalline matter resembled spermaceti; though, in a calculus analyzed by Gren, it seemed to approach more nearly to wax. The hepatic calculi have not been examined.

They often lie quiet in the gall bladder; and, until dissection after death, are not known to exist: but, when they are prevented from passing through the gall ducts, they generally obstruct the passage of the bile into the intestines, and produce many other distressing symptoms.

The diagnostics of this disorder are often obscure and uncertain; for other causes produce similar symptoms. An instance occurs in Mr. White's Treatise on the Disorders of the Bile: the usual symptoms, however, are, a loss of appetite, a sense of fulness in the

stomach, sickness, vomiting, languor, inactivity, sleeplessness, and, if the obstruction continue a few days, a wasting of the flesh; a yellowness of the eyes, skin, and urine; whitish stools; a pain at the pit of the stomach, without any change in the pulse. The last symptom is considered as peculiarly distinguishing this affection. This pain, which in some is extremely acute, in others light, is felt about the region of the liver, and its particular seat is in the gall duct, just where it enters the duodenum. In some patients the yellowness does not appear; in others it is observed for several months. It is a disease peculiarly painful, and as frequent as any disorder of the liver; it receives much relief from art, and is not immediately dangerous.

In the cure, pain is the first object of attention; and, when it is considerable, opium is the only resource: a dose may be taken as soon as the patient perceives its approach, and repeated every hour or two until a remission is procured. The vomiting, which generally attends, is nature's effort to dislodge the gall stones; and, whether it is present or absent, as soon as the pain begins to abate, an emetic should be administered, and repeated if required. After its operation an opiate may be given. Purging medicines are equally necessary; and of these, such as act with the most ease, and may be most safely continued, as manna, castor oil, the waters of purging springs, and neutral salts, are preferable. These may be repeated every other day for several months, without palling the appetite, or lessening the strength. A little rhubarb may also be taken occasionally. See London Med. Transactions, ii. 123. Memoirs of the Med. Society of London, i. 373.

The juice of grass and the decoction of its roots in the spring, are supposed, from a fanciful analogy, to be powerful solvents. Mr. White says that he hath given alcohol saturated with the oil of turpentine, and advantageous effects have been soon manifested.

See Dr. Coe on Bilious Diseases. Gooch's Cases and Remarks, p. 163—169. Lond. Med. Trans. vol. ii. p. 105, &c. Mr. White's Treatise on the Diseases of the Bile. Lewis's Translation of Hoffman's Practice of Medicine. Annales de Chimie, v. 186.

CALCULUS HUMA' NUS. See BEZOAR MICROCOSMICUM.

CALDA'R IÆ ITA' LICÆ. Hot baths near Ferrara, in Italy, useful in difficulty of urine.

CALDA'R IUM, quasi *calidarium*, (from *caleo*, to make hot). See BALNEUM.

CAL'DUS, for CA'LDUS, is frequently used by Scribonius Largus; and *calda*, by many authors, for warm water.

CALEFACIE'NTIA, (from *calefacio*, to make hot). Such medicines as warm the habit. They belong to the class of stimulants, and, from the effects they produce, are called calefacients. See STIMULANTIA.

CALEFA'CTIO. See CALCINATIO by calefaction.

CALE'NDULA, so called—*quod singulis calendis, i. e. mensibus florescat*—because it flowers every month. GARDEN MARIGOLD, called also *caltha, calendula sativa, chrysanthemum, sponsa solis*, SINGLE MARIGOLD. *C. sativa* Lin. Sp. Pl. 1304. Nat. order, *compositæ discotæ; corumbiferae* of Jussieu.

Of the many sorts of marigolds, this is the only one generally received in medicine. It is so common in

our gardens, that a particular description is needless. It is annual, propagates itself by seeds, and flowers from May to the end of autumn.

The leaves have more virtue than the flowers, their expressed juice contains most of their pungent matter: it is thought to be aperient, and to promote the secretions in general. The flowers are a slight cordial.

CALE'NDULA ALPINA. See ARNICA MONTANA. Lin. Sp. Pl. 1245.  $\beta$ .

CALE'NDULA ARVENSIS, the WILD MARIGOLD, also called *caltha arvensis*, *caltha minima*; *c. arvensis* Lin. Sp. Pl. 1303. These leaves are stinking and bitter, and if burnt in the candle they crackle like nitre.

It is sometimes preferred to the former. Its juice is given from one to four ounces in the jaundice and cachexia; and the leaves are commended as a salad for children affected with scrofulous tumours.

CALE'NDULA PALUSTRIS. COMMON SINGLE MARSH MARIGOLD. *Caltha palustris* Lin. Sp. Pl. 784. Also called *populago*, *caltha palustris*, *pseudo helleborus*, *ranunculoides pratensis*. Grows in marshes, and is very acrid. It is so caustic that cattle avoid it, for it excites an inflammation if they chance to swallow it.

CALENTU'RA, (from *calco*, to make hot). It is a violent ardent fever, in which a delirium comes on both early and suddenly. It happens to those who sail into very hot countries. Dr. Oliver gives the history of a case in the Philos. Trans. Abr. vol. iv. in which he observes, that when the delirium came on, the patient imagined that he was in green fields; that after a free bleeding he slept, and waked without any other complaint than weakness from the loss of blood, and soreness from struggling during his delirium. He further adds, that this fever attacks in the night, whence the patient, under the notion of green fields, runs into the sea before any one is aware, so that few of these cases occur to observation. Dr. Shaw advises, that the patient should indulge in rest, be bled freely, take a few hours afterwards an emetic; dilute plentifully with barley water, and that a blister should then be applied. It is probably a species of phrenitis, though of the milder kind, and of the nature of the *coup de soleil*. C. Stubbs in the Philos. Trans. N° 36.

CALE'SIUM. (Indian.) A tall tree, which bears clusters of berries like grapes or currants. These berries contain a flat stone with a kernel in it. It grows in Malabar. Of the wood is made sheaths for knives and swords. The bark, made into an ointment with butter, cures convulsions from wounds, and heals ulcers. The juice of the bark cures the aphthæ; and, taken inwardly, the dysentery. Raii Hist.

CA'LI, (from *kali*, Arab.) See CLAVELLATI CINERES.

CALICHA'PA. See SPINA ALBA.

CALIDRIS BELIO'NII. The French call it *chevalier*, from the length of its legs and swiftness of its motion. This bird is of the bigness of a pigeon; met with in meadows where there are pools and rivulets. It is the scolopax of Latham, and all the species afford a nourishing food.

CALIDUM INNA'TUM is an expression borrowed from the Stoical philosophy to express the natural heat of animals, which, as connected with life, has been also called *βιολυχιον*, the *lamp of life*. By the ancient philosophers in general, heat was considered as connected

with life, as the peculiar distinguishing property of living animals, or as the effect of divine interposition:

*Est Deus in nobis, agitante calescimus ifiso.*

The ideas of Hippocrates on this subject were not very different; and, though Galen deviated somewhat from his master, no attempts were made to explain its source, till the chemical schools attributed it to effervescence and fermentation; the mechanical philosophers to friction—either of the particles of the blood on each other; of these on the vessels; or of the solid parts themselves. Each of these theories is, however, wholly inconsistent with the appearances, or with the functions, of the animal economy; nor need we in this place enter into arguments to refute opinions which no one at present adopts.

Dr. Franklin supposed that fire, or, in modern language, caloric, was combined with our aliments; and, in the progress of the circulation, when the alimentary substances were decomposed, again separated in an active state: an idea simple and ingenious, in reality the basis of more modern systems. When phlogiston was in fashion, Dr. Black supposed that the air acting on the blood, separated the inflammable principle; and since it was apparently changed in the same manner as it would have been by a burning body, a similar process probably occasioned the change. Dr. Duguid Leslie, in his Thesis, afterwards published separately, opposed this idea; and suggested an opinion not very different from Dr. Franklin's, that the phlogiston contained in all our fluids, was separated during the circulation; and, as in every other circumstance where this principle was separated, heat ensued. This doctrine was, we believe, taught by Dr. Duncan in his class about that time: at least we have good reasons to attribute it to him. Yet each of these opinions must fall with phlogiston; but, though terms alter, we shall find that the principle of each has been retained, and that the same or similar ideas, in different forms, approach very nearly the solution of the problem.

The facts, however, have not been ascertained with accuracy. The heat seems to be almost uniform in every part of the body; and a thermometer under the tongue, in the axilla, in the rectum, in the urethra, and in a sinous ulcer, has pointed to nearly the same degree.

There is, undoubtedly, a difference in the degrees of heat of different persons, and probably in different parts. The earlier observations, as the construction of the thermometer was less correct, we shall omit; but, in general, the heat appears to vary from 96° to 98°. Dr. Martine and Dr. Hales found the urine to be 99° and 103° when the skin was 97°. Mr. Hunter observed the heat of the rectum to be 98°, and that of the bulb of the urethra 97°. A thermometer, two inches within the rectum of a dog, was at 100°, in the left ventricle of the heart 101°, in the substance of the liver 100 $\frac{3}{4}$ °, and in the stomach 101°.

De Haen, however, remarks, that if a thermometer be applied under the arm for half a quarter of an hour, its height is 95° or 96°; if for a quarter of an hour, 97°, 98°, and 99°; if for half an hour, 100°, and 101°; if for an hour, 101°, and 102°. This passage has been little noticed, though we suspect it is alluded to by an author, who remarks, that the irritation produced by any body confined so long to a part, must

increase the heat above its natural standard. To ascertain the fact, the author of this article put a very accurate and sensible thermometer, made by Dr. Wilson, of Glasgow, under his arm, when in perfect health; and, confining the humerus loosely, so as not to produce the slightest inconvenience, sat down to read. The pulse, as usual with him when sitting still for some hours, sunk to  $56^{\circ}$ , were the same in both arms, and the feelings in each arm continued the same for three hours, during which the experiment lasted. In a quarter of an hour the thermometer was  $97^{\circ}$ , in about an hour  $98^{\circ}$ , and in two hours after  $99^{\circ}$ . It never rose higher. We must add, that in other trials, when the author's heat has been compared with that of different persons, it has always been found at least a degree lower; so that, perhaps, the real heat of the human body should be considered as  $100^{\circ}$ . This fact is, we think, of importance, when, with the accuracy of modern chemists, the capacity of the blood for heat in different situations is estimated.

Another fact, for which we are indebted to De Haen, is, that in putrid fevers the heat at the moment of death has been considerably increased, and that it even continued to increase after death, till, if we recollect rightly, it amounted to  $104^{\circ}$ . To this meagre catalogue of facts we can only add one other, which we think should be again examined, viz. that the venous blood of the internal organs is hotter than the arterial.

Observation, which ought to have preceded theory, should have furnished many additional circumstances to assist our enquiries; and it would have been of advantage to have ascertained the comparative capacity of heat of the blood in the vena portæ and the hepatic veins, perhaps of the blood in the splenic artery and the vasa brevia; nor would it have been wholly useless to have determined the capacity of heat of the different component parts of the vital fluid, with more accuracy than has yet been attempted. We must proceed, however, to explain the modern theories of Dr. Crawford and M. Lavoisier, taking the liberty of changing the language of the former; for, though phlogiston is no more, the language only, so far his theory extends, is changed.

We must anticipate a little the doctrines of an approaching article (CALORIC), by explaining some terms essentially necessary to the proper comprehension of Dr. Crawford's system. If we suppose at this moment the existence of heat as a separate principle admitted, *absolute heat* is the real quantity of this principle; *relative heat* that quantity only which is obvious to the senses, or can be measured by a thermometer. Thus, according to the common instance, a pound of water and as much calx of antimony have the same temperature to the thermometer; but the water contains four times as much heat as the calx. The capacities of bodies for retaining this principle, are also different and measured by the degrees of sensible heat in each, after being exposed to the same temperature. Thus, if water and mercury are exposed to the same heat for a given time, while the temperature of the water is raised one degree, that of the mercury is raised  $28^{\circ}$ . The capacity of water then to that of mercury, is as 28 to 1. These two qualities, absolute heat, and capacity for heat, are often confounded, and particularly by Dr. Crawford, who was not aware, that in the diaphoretic

antimony the heat was really a component part of the calx.

In pursuance of the general distinction between absolute and relative heat, Dr. Crawford examined the arterial blood compared with water, and found it to be as 1.03 to 1.00. He consequently suspected, that the blood absorbed heat from the air in the lungs; and this idea was confirmed by the intimate connection between the increase of temperature and the frequency of respiration, as well as the extent of the respiratory organs. On pursuing the enquiry, he found that the absolute heat of atmospheric air was changed by passing through the lungs; and, in general, air contained absolute heat in the same proportion that it was adapted for respiration. On examining the state of the blood in the pulmonary vein and artery, he found the heat greater in the former than in the latter. The colour of the venous blood resembles more nearly that of arteries in a warm than in a cold atmosphere, for less heat is of course absorbed; and, in general, the heat absorbed by air is nearly the quantity produced by burning a wax taper, for the air is vitiated in nearly the same proportion by both processes. The absolute heat of different animal substances he ascertained to be as follows. Supposing water 1.0000, inflammable air was 21.4000, oxygen gas 4.7490, atmospherical air 1.7900, aqueous vapour 1.5500, carbonic acid gas 1.0454, azote 0.7936, arterial blood 1.0300, venous blood 0.8928, fresh cows' milk 0.9999, hide of an ox with the hair 0.7870, lungs of a sheep 0.7690, lean beef 0.7400.

To apply these facts to the subject before us, he found that the absolute heat of pure air, at the common temperature of the atmosphere, was equal to  $1550^{\circ}$ . The heat of fixed air and aqueous vapour being one third less, pure air changed to the two latter, would give out  $3 \times 1550^{\circ} = 4650^{\circ}$ . Many causes concur to reduce this quantity, but it will be evident that a large proportion of heat must be absorbed by the blood, as so little sensible heat is produced.

The capacity of the heat in venous blood, appears to that of arterial as about 23 : 20. If venous blood be therefore converted to arterial, there will be this proportional loss of heat; but venous blood contains  $1580^{\circ}$ , and consequently the loss from the change of venous into arterial blood, would be very nearly  $200^{\circ}$ , if the deficiency were not supplied from the air. We now know, also, more clearly than at the period Dr. Crawford wrote, that oxygen contains a considerable proportion of caloric, and its abstraction is of course connected with a diminution of this principle. As oxygen, therefore, disappears in respiration, heat is lost to our senses, but recovered again in the increased capacity of the blood, after it has circulated through the lungs. The blood in circulation becomes replete with azote, and, of course, its attraction for oxygen is diminished. Heat, therefore, escapes in every part of the circulating system, and supports an equable warmth; till the blood, returning to the lungs, again absorbs a fresh proportion of oxygen from the air, to be again partly separated for the support of animal life: we say partly, for the capacity of the remaining fluids being increased, a portion is absorbed, and becomes of these a component part.

This doctrine is recommended by its simplicity, its conformity to other appearances, and the ready application it affords to different phenomena; particularly

the connection of animal heat with the extent of the respiratory organs, and the frequency of respiration. It explains also some other facts which require a more ample consideration.

The heat of animals, at whatever degree it may be placed, is uniform. We see that the lower the surrounding temperature is, the separation of the oxygen from the air will be more complete, and, of course, the separation of heat in the circulation. The arterial and venous blood will, as we have said, differ nearly in the same proportion in their colour. Thus the changes balance each other; and in warm countries, where putrefaction powerfully vitiates the air, breathing has a proportionably less effect.

This balance of the effects of heat in the air, and of the production of animal heat, goes further; for, when heat is increased beyond its due bounds, the same principle produces cold. Mr. Tillet found that a girl could live for some time in an oven heated to  $220^{\circ}$ ; and Dr. Fordyce observed that a dog could live, with little inconvenience, in a heat of  $260^{\circ}$ ; and he himself endured the heat of  $230^{\circ}$  for fifteen minutes, while the thermometer under his tongue pointed only to  $100^{\circ}$ . Dr. Crawford proved, that when a living and a dead frog were exposed to a great degree of heat, in air or water, the former acquired the heat of the surrounding temperature more slowly than the latter. These facts are readily explained from our author's system. It appears, from what we have observed, that the blood brings with it to the lungs such an increased capacity for containing heat, that if its temperature were not supported by the oxygen of the air, it would sink  $200^{\circ}$ : but, in great heats, this capacity is supplied, and a small proportion only is absorbed; in very high degrees of temperature, probably none: and when, from the changes produced by the circulation, this extraordinary proportion of heat is separated, as it will be by the more rapid increase of the animal process, the superabundant heat is lost in the aqueous vapour, and in the evaporation, or rather the change of that vapour into air. Thus we see, also, why the heat in putrid fevers is so considerable, and why it may even increase after death; for the putrid fluids, having a less capacity of heat, lose whatever they contained in consequence of their former capacity, and putrefaction, hastening on rapidly after death, indeed more rapidly than the heat can be carried off, occasions its apparent increase.

The opinion of MM. Lavoisier and Seguin is more simple, but by no means meets so satisfactorily the phenomena, as the theory of Dr. Crawford. They consider respiration as a kind of combustion, in which pure is converted into fixed air, and the heat separated as the cause of animal heat. This, however, establishes a focus of heat in the lungs. This part must be the warmest, and the extremities the coldest, in the body, while the heat of the intervening parts must vary in proportion to their distance from the centre of inflammation. They avoid this difficulty, however, by alleging the rapidity of the circulation; and they elude the consequence of extraordinary heat in the lungs, by its diminution in consequence of evaporation; but, if examined, neither would be found equal to the effects. Lavoisier, however, adopts part of the idea of Crawford; and, when we recollect that the work of this latter author appeared in 1779, and the improved system of Lavoisier in 1780, we shall not doubt to whom this ad-

dition is owing. On the whole, the system of Dr. Crawford is apparently the true one. In the first edition there were some errors, both in the experiments and calculations; nor is the second, perhaps, though much more perfect, wholly free. Modern discoveries have, indeed, added to Dr. Crawford's system, and confirmed it; for, whether we consider the formation of carbonic acid gas from the addition of carbon, or that of water by the union of hydrogen, we shall find that in each change the vital air must lose a part of its specific heat. Yet it may be alleged, that Dr. Crawford, by ascertaining the capacity of aqueous vapour and of venous blood, has given a solution, though not so particular, equally satisfactory.

Various modifications of these opinions have been published. M. Girtanner, in the *Journal de Physique* for the year 1790, has suggested an opinion, that a part of the oxygen of the atmosphere unites with the arterial blood; a part with the carbon in the carbonated hydrogenous gas, which escapes from venous blood, forming carbonic acid gas; a part with the mucus, which is constantly decomposing; a part with the hydrogen gas of the blood to form water; and a part only remains in the blood to supply the animal heat. The effects of respiration will, therefore, be very numerous and different; but, when the products are examined, they will, he thinks, be found the same with those of combustion. If Dr. Crawford's system be considered with attention, it will not, we suspect, be found to require such a complicated process.

De la Grange adopts the opinion of Dr. Duguid Leslie, or rather of Dr. Duncan, putting it only into a modern dress; and Hassenfretz does not greatly differ.

Dr. Gren, in the *Annales de Chimie*, supposes that no oxygen is communicated to the blood; but that the change from the venal to the arterial is owing to the separation of carbon and hydrogen, with which the oxygen forms carbonic acid, and the water expired in respiration. M. Metheric, in the *Journal de Physique*, will admit only of the combination of oxygen as *one* cause of animal heat, recurring as assistants to muscular motion and fermentation. Respiration, he thinks, conducts the electrical fluid to the blood, as the air of an apartment in which a person has long breathed, is electrified negatively; but this proves nothing, as all our excrementitious fluids possess a negative electricity. Linnæus hints at a similar cause of the heat of animals, when he observes, in his concise, energetic language, *Flagrat electrico pulmonibus hausto*.

Dr. Menzies' experiments are connected rather with the subject of respiration than with animal heat; and we need only remark, that he thinks all the heat observed in the animal system may be explained from the quantity of pure air vitiated in the lungs; thus referring the heat of animals, like Lavoisier, to a species of combustion. The conclusion is, however, more correct in a chemical than in a physiological view. It will undoubtedly explain the heat of the blood in the lungs; and if Mr. Hunter's experiments, formerly mentioned, be admitted, for a little increase of the heat in those organs; but it will not explain the nearly uniform temperature in different parts. Indeed, we know of no system which so readily meets all the physiological and pathological facts as that of Dr. Crawford, and it is, we believe, generally adopted. See RESPIRATION.

To this system, however, one objection remains, viz. the heat, which the embryos of animals, and particularly of oviparous ones, possess, independent of the parent. As the blood, however, of the fœtuses of viviparous animals passes regularly through the lungs of the mother, it may be supposed to convey sufficient heat for the embryo; and, in confirmation of this idea, the blood of pregnant women seems to be highly oxygenated. No blood from the mother, however, can reach the embryo inclosed in an egg; and, though nature has provided a reservoir of air at one end, it is too inconsiderable to supply the young animal with warmth. It is singular, however, that the nature of this air has not been examined; nor has it been ascertained, though the quantity is known to be diminished in the progress of incubation, whether it undergoes any chemical change. Yet, as the yolk by which the chick is nourished, and the albumen itself, contain oxygen, this may be gradually evolved and impart its caloric; nor is this change merely imaginary, for we know that the mild fluids of the egg are gradually changed to azotic ones, whose capacity for heat is of course diminished.

There are, however, many arguments which lead to Dr. Cullen's opinion, that the warmth of animals is connected with their life, and the effect of the principle which distinguishes them as living beings. It is certain, also, that vegetables which possess life, possess also some innate heat; though the change respecting the air, the inhale and exhale, is reversed; for they expire oxygen as an excrementitious fluid, while they draw in carbon at the radical fibres, and absorb hydrogen probably from the leaves. At present, however, we know too little of the vegetable economy to suffer a system, otherwise highly probable, to be disturbed by its apparent anomalies; and, while we thus put our readers in possession of all the facts, we shall leave the ultimate decision for the result of further investigation.

Lavoisier and De la Place; *Mémoires de l'Académie*, 1790; Menzies on *Respiration*, 1796.

CALIE'TA, or CALIE'TTE, (from *καλις*, a nest, which it somewhat resembles). See JUNIPERINUM LIGNUM.

CALI'GO, (from *caligo*, to be dark). A growing darkness of the eye, or dimness of the sight, from a manifest cause; as in cases of the cataract, &c. Dr. Cullen places this genus of disease in the class *locales*, and order *dysæsthesiæ*. He defines it to be sight diminished, or wholly abolished; from a dark barrier between the object and the retina, in the eye itself, or in the eye lid. He also enumerates five species; viz.

1. CALI'GO LENTIS; the *glaucoma Woolhousi*, maître *Jean St. Yves*; this he denominated the cataract, and Sauvages calls it the true cataract, it is caused by a thickening of the coats of the crystalline lens. See CATARACTA.

2. CALI'GO CORNEÆ, from an opacity of the cornea. See ACHLYS and ALBUGO.

3. CALI'GO PUPILLÆ, from obstruction in the pupil.

See SYNIZESIS; called also *amaurosis et synchysis a Myosi*.

4. CALI'GO HUMORUM, GLAUCOMA VOGELII, from a fault in the humours of the eye.

5. CALI'GO PALPEBRARUM, from a disorder in the eye lids. See Cullen's *Nosology*, edit. 3.

CALIHA'CHA. See CASSIA LIGNEA.

CALLÆO'N, (from *καλλωνω*, to adorn). The GILLS of a cock, a food neither to be praised nor condemned. Galen.

CALLE'NA. A kind of SALTPETRE. See NITRUM.

CALLI, *πορα*. Nodes in the gout. Galen.

CALLIBLE'PHARON, (from *καλος*, beautiful, and *βλεφαρον*, an eye lid). Medicines appropriated to the eye lids.

CALLICOCCA, Lin. Gen. Pl. Schreber, 316. Nat. order *rubiceæ*, Juss. See IPECACUANHA.

CALLICRE'AS, (rom *καλος*, good, and *κρεας*, meat). See PANCREAS.

CALLI'GONUM, (from *καλος*, beautiful, and *γονν*, a joint, or knot; so named from its being handsomely jointed). See POLYGONUM.

CALLIOMARCUS. See TUSSILAGO.

CALLIONYMUS, (from *καλος*, good, and *ονομα*, a name). See URANOSCOPUS.

CALLIPHY'LLUM, and CALLITRI'CUM, (from *καλος*, beautiful, and *φυλλον*, a leaf, or *τριξ*, a hair). See ADIANTHUM NIGRUM.

CALLOSITAS, CALLOSTITY. See CALLUS.

CALLUS. From *calx*, the heel, or *calco*, to tread; because it used to be applied to the thick skin at the bottom of the heel, hardened by pressure; but it is a cutaneous or osseous hardness, either natural or preternatural. Generally it means the *callus* generated about the edges of a fracture. Sometimes it means a corn on the toes, the hardness in the hands produced by labour, or the hard edges of ulcers. See Bell's *Surgery*, ii. 326. Kirkland's *Med. Surgery*, ii. 246.

This term and *callositas* are, in a special sense, spoken of the eye lids, both by Galen and Scribonius Largus; and *callus* has a particular signification, in which it means the *corpus callosum* of the brain. Paracelsus gives the name of *callus* to an abscess, or ulcer, caused by acrid juices which excite violent itching. For *callus* on the hands and feet see CLAVUS.

The retraction of the part divided is a common symptom in wounds; and the stronger the contractile force, the more the sides of the wound recede from each other. The skin of the head is thick and strong, and equally tense on all parts of the skull, and under it lays a cellular membrane; so that when the skin of the cranium is divided, the lips of the wounds are far retracted, and are called *callus*, consequently wounds of the forehead generally leave large scars behind them.

As the growing vessels in wounds of the soft parts are tender in consequence of their not being pressed by the skin, they may degenerate into fungous flesh. The same holds true in the *callus* of the bones, which may become luxuriant when the vessels which constitute the substance of the growing bone are distended, either by a redundancy, or too strong impetus of the fluids.

Dr. Nisbet and Dr. Hunter imagine a *callus* of the bone is not formed by the inspissation of any fluid, but from a regeneration, or, as it were, granulation from the fibres of the bone.

CALMET. See ANTIMONIUM.

CALOCATANOS, (from *καλος*, *beautiful*, and *καλον*, *a cup*; so called from the beauty of its flower and shape). See PAPAVER RUBRUM.

CALOMELANOS TURQUETI. So Riverius calls a certain purgative medicine which he often used. It is thus prepared.

R. Merc. dulc. ʒ j. gum. scammon. cum sulph. impregn vel rez. jalap. ʒ ss. mucilag. ẽ gum. trag. q. s. f. pil. mediocr.

CALOME'LAS, (from *καλος*, *good*, and *μελας*, *black*). It used to be called Ethiops mineral. But *calomelas* is, in common acceptation, the *mercurius dulc. sexties sublimatus*, which, if ground with the volatile spirits, becomes black: it is called also *aquila alba*. See ARGENTUM VIVUM.

CALOMO'CHANUS, or CALOMOCHNUS. See ADARCES.

CALONIA. So called from the place where it was procured. CALONIAN MYRRH. Hippocrates often prescribes it.

CALORIMETER. An instrument contrived by Lavoisier and De la Place, to measure degrees of heat separated. Mr. Wedgewood, Philos. Trans. 1784, has offered some objections to this instrument, which M. Berthollet replies to in Chemical Statics, vol. i. p. 404.

CALORICUM, (from *calor*, *heat*). CALORIE. Lavoisier, in giving his reasons for the adoption of this term, says, "All bodies are either *solid*, *liquid*, or in a state of *aëriiform vapour*, according to the proportion which takes place between the attractive force inherent in their particles, and the repulsive power of the heat acting upon them; or in proportion to the degree of heat to which they are exposed. It is difficult to comprehend the phenomena, without admitting them as the effects of a great and material substance, or very subtle fluid, which, insinuating itself between the particles of bodies, separates them from each other. This substance, whatever it is, being the *cause of heat*; or, in other words, the sensation, which we call *warmth*, being caused by the accumulation of this substance; we cannot, in strict language, distinguish it by the term *heat*, because the same name would very improperly express both cause and effect." He therefore gave it the names of *igneous fluid*, and *matter of heat*. These periphrastic expressions, however, lengthen physical language, render it more tedious, less distinct and correct, so that the cause of heat, or that fluid which produces it, has been distinguished by the term CALORIE, considered as the respective cause, whatever that may be, which separates the particles of matter from each other. See Elements of Chemistry, p. 5.

There is, however, an intermediate state of water in air, or rather approaching the form of air, which M. Lavoisier has not considered, viz. *vesicular vapour*. It contains a greater degree of specific heat than water, and less than either of the permanent elastic gases. Its form, however, does not seem wholly to depend on its heat, but on its electricity; by which it is repelled from the higher regions, and does not descend in rain. This is the state of water in fogs and in clouds; but as this subject admits of no application to medicine, we need not pursue it in this place.

We have anticipated the distinction of absolute and relative heat in our article on CALIDUM INXATUM, q. v. and shall now pursue its other effects.

When we speak of heat and its effects, we measure a

very small part of an extensive scale. It is computed, though on no very secure foundation, that at about 1500° below the scale of Fahrenheit, it no longer exists; and we have in our power a degree equal to 32277° of that scale, the highest heat measured by Wedgewood's pyrometer. Our limits are between the 32d and the 120th degree of Fahrenheit, scarcely 88 degrees, yet even the effects of these changes are interesting.

Expansion is one of the first and most striking effects. So far as it is applicable to the human body, we have noticed it under the article of BALNEUM, and may again advert to it under that of HEAT. We there mentioned the blood as one of the least expansile fluids; but, as in the experiment some gas must escape, a little inaccuracy might be suspected. We had then in our view the experiments by Lavoisier, Prony, Guyton, and Prieur, on the expansibility of different gases; of the considerable and equable expansibility of carbonic acid gas; and the very great expansibility of azotic gas in high temperatures. We find, however, from a Memoir of an ingenious chemist, Guy Lussac, an abstract of which occurs in the Annales de Chimie for 1802 (Thermidor, an X.), that when every cause of error is removed, particularly the presence of water, atmospheric air, oxygen, hydrogen, azote, nitrous, ammoniacal, carbonic, sulphureous, and muriatic acid gases, as well as the vapour of sulphuric æther, are dilated equally by the same degrees of heat; and that in the centigrade thermometer, from 0 to 80°, each dilated about  $\frac{1}{273}$  of its bulk for each degree. Of the fluids, the most expansile is nitric acid, then linseed oil, sulphuric acid, alcohol, water, and mercury, in their order. Of the metals, the expansibility is nearly in the order of their fusibility, viz. zinc, lead, tin, pewter, brass, copper, bismuth, iron, steel, antimony, and platina. Of liquids the expansion is different, but few expand equably, viz. in equal degrees with equal increments of heats. Those which approach nearest to an equable expansion are mercury and alcohol, and are consequently preferred for filling thermometers. This effect of heat admits but of little application in the practice of medicine. Cold applications in hernia and in topical inflammations, are the principal remedies which act in this way; though the latter admit of a somewhat different explanation.

Another effect of caloric, is the equilibrium which it affects: but this admits of modifications which we have already explained. The heat which raises one body a given degree, very slightly affects another; but to the touch and the thermometer the heat is in time the same. This law of heat chemists have found it difficult to explain. The popular idea, though not a correct one, may be the usual allusion of a sponge, which suffers the superabundant fluid to escape when its pores are filled. This allusion also explains another effect, viz. when any body is dilated, heat is absorbed, when compressed, it escapes. Thus, in an exhausted receiver, if the air is humid, a cloud is formed on exhaustion. In a condensing engine we find heat escape sometimes rapidly; and, when suddenly dilated before the air can again absorb the free heat, even inflammation has taken place. We must repeat, however, that this allusion to the sponge is by no means correct. The equilibrium of heat depends rather on affinity, though apparently subject to some peculiar laws, and is little connected with physiology, as it relates to free caloric, and not to absolute or specific heats.

The laws of heat, most interesting to the chemical physiologist, relate to the powers of different substances in conducting heat. The motion of heat is slow, particularly when the conductors are fluids. Some authors, confounding heat with light, have given the former the velocity of the latter. They are, however, essentially distinct; and when air and water are interposed between small filaments of a solid, its motion is peculiarly slow. This renders feathers, eiderdown, and boiled mashed apples, bad conductors of heat: metals of every kind are, for the opposite reason, good conductors. We preserve the heat of the body by fur and eiderdown, and apply rasped potatoes to burns, which keep the part constantly cool. Count Rumford endeavoured to show that water was a non-conductor of heat, and that it boiled in a vessel over the fire by successive currents coming in contact with the bottom. Such currents evidently exist, and explain the common paradox of the bottom of a kettle being cold while the water boils; but that water is a non-conductor of heat, can be by no means concluded from the experiment. On the contrary, Dr. Thomson has shown in Nicholson's Journal, vol. iv. p. 159, that water really conducts heat. Metals we have said are good, indeed they are the best, conductors. Of these, silver is better than gold, and this last metal excels copper and tin, which do not greatly differ. Platina, iron, steel, and lead, are greatly inferior, and nearly in this order. Next follow stones, then glass, and afterwards dried woods, fine sand, charcoal (*Annales de Chimie*, xxvi. 225,) feathers, silk, and wool, in the inverse ratio of their fineness. Of fluids, Dr. Thomson found an equal bulk of mercury to be twice as good a conductor of heat as water; and linseed oil somewhat better. It is highly probable, that the conducting power of bodies is in the ratio of their affinity for heat.

Bodies of different colours convey heat also differently. The difference between white and black is well known; and the more intense colours, as red, orange, &c. convey it more readily than the blue or indigo. If heat and light are distinct bodies, as is now generally supposed, and light only excites the action of caloric, we can easily understand why bodies which reflect all, or the greater proportion of light, excite little heat. Count Rumford, in the *Philosophical Transactions* for 1804, has shown, that blackening a cylinder expedited the cooling of water in it: in fact, the communication of heat from bodies to air is slow, and an intermode of less density, if no air is interposed between its particles, facilitates it. Another reason of this unexpected effect is the destruction of the polish. Polished surfaces communicate heat slowly; and this is an additional reason for the warmth of furs, whose fibres possess a high polish. For this reason silk clothes are cold; and even black clothes, in this author's opinion, *in the shade*, are cooler than those of other colours.

Of specific and absolute heats we have already spoken at sufficient length. Specific heat, however, depends on the affinity between the body and caloric; and consequently is in the inverse ratio of their conducting power. We shall add, therefore, a table of the specific caloric of different bodies, collected from the tables of Mr. Kirwan, M. Meyer, and some others, by Dr. Thomson.

TABLE of the Specific Caloric of various Bodies, that of Water being = 1.0000.

Bodies.	Specific Gravity.	Specific of equal weight.	Caloric of equal volumes.
I. GASES.			
Hydrogen gas - - -	0.000094	21.4000	0.00214

CA'LTHA, or CA'LTHULA, (corrupted from *καλ-  
α, yellow*). MARIGOLD. See CALENDULA.

CA'LTHA ARVE'NSIS, MI'NIMA. See CALENDULA ARVENSI.

CA'LTHA PALUSTRIS. See CALENDULA PALUSTRIS.

CA'LTROPS. It derives its name from the form of its fruit, which resembles those instruments of war which were cast in the enemy's way to annoy their horses. This plant is also called *tribulus*; *trapa natans* Lin. Sp. Pl. 182. The fruit is nutritious and demulcent, of use in diarrhœas from abraded bowels, and it is said in the stone.

CA'LVA, CALVA'RIA, (from *calvus*, bald; so called because it is often bald). See CRANIUM.

CALVA'TA. See PHALACRA.

CALVITIES, CALVITIUM, (from *calvus*, bald). See ALOPECIA.

CA'LV. This word is applied to whatever is subjected to calcination, or change from burning. It chiefly refers to metals after having sustained the action of fire; and to calcareous earths, which are burnt to lime. See CALCINATIO.

LIME STONE, also called *saxum calcarium*, *abesum*, *algeria*, is a general name for all those stones from which quick lime is commonly prepared. Though the limes prepared from different stones answer many general purposes equally well, they differ greatly in their efficacy in medicine, and in many chemical and other experiments.

When stones of the calcareous kind have been calcined by the fire, they are converted into quick lime, called CALX VIVA, and in some obsolete authors, *anora*, *gir*, *nix fumans*, and *almyzinthra*.

Quick lime dissolves in nitrous, marine, and vegetable acids; unites with the vitriolic into selenite, an earthy salt, scarcely soluble and insipid; produces heat on mixing with water, imparting to it a medicinal quality. If quick lime is exposed to the atmosphere, it falls into a powder, and loses all its distinguishing properties except that it retains its acrimony longer in a moist than in a dry state.

The stones from which quick lime is produced contain a large quantity of air, which, in calcination, is expelled: hence strong quick lime raises no effervescence, and emits no air bubbles during its dissolution in acids.

CA'LV VIVA, or QUICK LIME, is lime in its most caustic state, with the air wholly separated. When styled *extincta* it has been long exposed, and fallen to powder. When deprived of its acrimony by repeated affusions of water, it is called WASHED LIME.

Calcareous earth is commonly found saturated with aerial acid, which exhibits the appearance of effervescence upon being driven from its basis by a stronger acid. It is found dissolved in most waters by means of a redundant portion of this acid, which by burning is

lost, together with a proportion of water with which it was combined. It also absorbs a considerable proportion of caloric, which on slaking is let loose.

Quick lime is employed for increasing the activity of alkaline salts, for making the milder kinds of caustics, and for destroying the hair on places where it is thought to be unseemly; it dissolves sulphurs and vegetable resins, and produces many effects similar to those of the fixed alkaline salts.

It has been also often employed in paralytic affections; and Cœlius Aurelianus directs us to rub palsied limbs with this earth. Mixed with honey, it is employed as a stimulant by Tissot; and with different ointments in the morbus coxarius by De Haen. Two parts of lime, as much wheat flour, with four parts of hog's lard, are employed in the Bath hospital in tumours of the knees (Falconer on Bath Waters). Severinus recommends a formula of quick lime not strictly chemical as a caustic. He mixes it with soap, and sprinkles it with the sharpest vinegar; which will consequently lessen the acrimony of the former ingredients. Quick lime, however, with soap, was long a favourite remedy; and is spoken of with commendation, by Heister, in warts and tumours of every kind. As promoting suppuration, with flour and lard, it is recommended by Valentine; and is generally useful in destroying the spots on the skin, supposed to be owing to the irregular fancies of the mother's appetite during pregnancy.

Internally it is employed only in its watery solution. In the London dispensatory, twelve pounds of boiling distilled water are added to half a pound of lime, and infused for one hour. The Edinburgh college order four ounces of water to be first added to the lime, or as much as it will absorb. When the lime has fallen into a powder, the remainder of the water is mixed with it, stirring the whole together, and the agitation must be often repeated. There is a little too great refinement in both: distilled water is unnecessary in the first, and the frequent stirring in the second. If, in the latter formula, the remaining water is well mixed, and suffered to remain on the lime in a covered vessel for a night, the water will be as strongly impregnated with the earth as its affinity will permit. If the water is heated, the taste is said to be less disagreeable. The lime, in both formulæ, is greatly in excess, for a very small proportion only is soluble in water; but it is cheap, or rather, in such small quantities, of no value.

The choice of lime is of consequence in agriculture and the arts, but of little in medicine. Mr. Tennant has informed us that limestone, mixed with magnesian earth, is injurious in agriculture; and the tanner is peculiarly anxious that *his* lime should be well burnt. Dr. Whytt thought that the lime from oyster shells was the strongest; but the difference seems only to consist in its being more completely calcined to separate the animal gluten. In general, the deficiency in the calcination, if it exists, is compensated by the quantity; and lime water may easily be made as strong as the stomach will admit.

The *lime water* is a solution of the quick lime in water, and receives no improvement from the ingredients added in the compound sorts which used to be ordered, for they precipitate much of the lime which the water suspended. The taste is acrid and earthy;

the smell pungent. With its taste, the lime water loses its virtues. It hath a strong styptic taste, which is followed by a sweetish one: it changes the juices of blue flowers to a green; it precipitates metallic bodies that are dissolved in acids; it tinges silver of a copper hue; it turns red wine to a dark colour; and by those properties its strength may be estimated.

The specific gravity of water is increased by the lime more than the weight of the calcareous matter taken up, on account, perhaps, of the water being deprived of its air.

If lime water is close kept, it may be preserved many months; but in open vessels the calcareous matter absorbs carbonic acid, and soon separates from the water, concreting on its surface. The earth which floats upon the surface of lime water fresh made, is called *calcis vivi flores*, but it is in reality only the carbonated lime.

Its virtues are also destroyed by every substance containing fixed air; the vitriolic, phosphoric, oxalic, or tartarous acids, as well as by astringents. Milk covers its acrimony very successfully without impairing its virtues.

Lime has been often employed with olive oil in burns; and when we recollect the changes produced on the acrid serum that exudes in the vesicles, by the calcareous earth in Mr. Cleghorn's poultice, little doubt will remain of its having a good effect. If by uniting with this serum it produces some warmth, it will not on this account be injurious.

In the stomach, lime water corrects acidity; but, though out of the body it has been found antiseptic (Hales and Macbride), in the stomach it has probably a contrary effect; for when acids abound, putrefaction is checked. In hot bilious habits, by destroying the natural corrector of bile, acidity, it is also injurious; nor do we think it can strengthen the stomach or assist digestion, as some authors have supposed, except where acids greatly abound. Perhaps, from its antacid power, though its astringency in the primæ viæ is by no means equivocal, it relieves old diarrhœas; and in some cases of dysentery has been successful. Grainger, in the Edinburgh Essays, mentions its having succeeded after being continued three weeks, when the patient took three pints daily. Xavier mentions its utility, with milk, in destroying the poison of arsenic in the stomach, or counteracting its effects. We have already mentioned the expectation we had entertained of its dissolving the viscid mucus in this organ, and our disappointment. Some experiments, recorded by Gaber, in the Turin Transactions, seem to support its utility in this respect; but they were not made on the mucus of the stomach. In leucorrhœa, it has been supposed to be very beneficial.

Perhaps the idea of its dissolving viscid fluids occasioned its being employed in intermittents, in pleurisy, in mesenteric and other scrofulous tumours, in rheumatism, and gout. We see Kempf seriously engaged in examining its solvent power on the pleuritic crust of the blood; and the step from calculous to arthritic concretions was too obvious to be overlooked. We cannot deny its utility in gout; but in the other complaints it is certainly of very little importance. If it possessed any power in dissolving viscid mucus, it would very probably be a more useful anthelmintic than it has been found.

From its astringent power it has been an useful ap-

plication in old ulcers; and from thence it seems to have been supposed serviceable in scurvy, in cancer, and in internal ulcers, when swallowed. Names of uncommon celebrity have given a sanction to its use in these complaints; and Vogel, in a dissertation published at Gottingen in 1769, speaks of its efficacy in cancer, given in the quantity of six and eight ounces of lime water, with as much common water, boiled with sarsaparilla or guaiacum; interposing, every four or eight days, Beecher's balsamic pills.

In Germany it has been very generally employed in internal ulcers of the uterus, the bladder, and even in ulcers of the lungs. In the latter, however, we are informed by Quarin that it is useless or hurtful. Girtanner recommends it as an injection in gonorrhœa; and, from the time of Hippocrates, it has been used as a lotion in all the variety of chronic cutaneous eruptions, especially if attended with exudations. For this purpose it is also taken internally; and it has been recommended to nurses, to prevent the child from being affected. Indeed, cutaneous eruptions are very intimately connected with a disordered state of the stomach, and often with a redundant acid. As an astringent it has been applied externally with a sponge to dropsical swellings; and Fabricius, *ab Aqua pendente*, informs us, that he cured an ascites by frequently applying a sponge moistened with lime water to the abdomen, and confining it with a tight bandage. Of its lithontriptic power we have spoken at some length in the article CALCULUS, q. v.

We find numerous cautions in various authors respecting its use in different situations where they suppose it to be injurious. We have already mentioned, however, the inconveniences that might result where the stomach and bowels are loaded with bile; and we should suppose it likewise improper in all cases of hectic fever. We are told, however, that it must be also avoided in all fevers; in hot climates; in dry and hot temperaments; in congestions of blood, either affecting the head or kidneys; in spasms; in the early stages of dysentery; 'in orgasms of the blood, and discharges depending on them;' in inflammatory habits and tense fibres; in obstructions of the bowels, or any diseases in them arising from scybala, till these are removed. Caution is at all times requisite; but we do not think it a medicine of so great power as to require so much attention. The last remark, we would, however, wish to enforce.

See CRETA; Neumann's Works; Experiments, &c. on Quick Lime, by Mr. Henry; Macbride's Essay on the dissolving Power of Quick Lime; Percival's Essays, Med. and Exp. edit. 2. p. 328; Lewis's Mat. Med.; and the Edinb. Ess. Phys. and Lit. vol. i. art. 13. and vol. ii. art. 8. Dr. Whytt on Oyster Shell Lime Water.

CA'LX ANTIMONII. See ANTIMONIUM.

CA'LX CUM KA'LI PU'RO. See CAUSTICUM COMMUNE FORTIUS.

CA'LX HYDRA'RGYRI ALBA. See ARGENTUM VIVUM.

CALY'PTER, (from *καλυπτω*, to hide). A carnosus excrescence covering the hæmorrhoidal vein.

CALY'PTRA, (from *καλυπτω*, to hide). A VEIL. It is the thin involucrum or cover of some seeds, used by former botanists to express that which Linnæus

means by *arillus*: also a thin cup which covers the *antheræ* of some of the mosses.

CA'LYX, CALIX, or EMPALEMENT, (from *καλυπτω*, *tego*, to cover). The first of the seven parts of fructification, by Linnæus defined to be the outer bark of the plant present in fructification. In general it is that green cup which supports the bottom of the corolla, and is otherwise called *perianthium* or cup, *involucrum*, *amentum* or katkin, *spatha* or sheath, *gluma* or husk, *calyptra* or veil, *volva* or curtain, as it happens to be differently circumstanced. It is generally single; in some plants double; and in others entirely wanting. It is commonly divided into the same number of segments with the corolla. The calyx commonly withers when the fruit is ripe, which distinguishes it from *bractææ* in dubious cases. It is generally less in point of height, but more substantial than the corolla.

CAM. An abbreviation of Joach. Camerarius de Plantis Epitome.

CA'MARA, or CAMA'RIMUM, (from *καμαρα*, a vault). The fornix of the brain. Likewise the vaulted part of the auricle leading to the external foramen.

CA'MARA. See VIBURNUM.

CAMARO'MA, CAMARO'SIS, CAMERA'TIO, (from *καμαρα*, a vault,) an arched roof; a fracture of the skull, which appears like an arch of a vault.

CA'MARUM, vel CA'MMORUM, (from *καμαρα*, a tortoise). A species of shrimp of the crab kind, which has a shell like a tortoise; also the *aconites*, and, according to some authors, *cicuta*.

CAMBING, a tree of the Molucca islands, whose genus is unknown, but whose bark has been recommended in dysenteries.

CAMBO'DIA, CAMBO'GIA, CAMBO'GIUM, (from *Cambogia*, from whence it is brought). The Indian yellow orange of Malabar, *coddam pulli*. It is the *garunia Cambogia* of Gærtner, the *Cambogia gutta* Lin. Sp. Pl. 728. The fruit is slightly acid, and supposed to be astringent. See MANGOUSTAN.

CA'MBRO BRITA'NICA. See CHAMÆMORUS.

CAMBU'CA, or CAMBU'CA MEMBRA'TA. *Bubo, ulcus*, or abscess on the pudenda; also a boil in the groin.

CA'MBUI. The wild AMERICAN MYRTLE of Piso and Marcgraave. There are two species. Their fruit, flowers, and leaves, are fragrant and astringent. One species is low and bushy, the other very tall. Ray says there is a third species which is white, but is very rare.

CAMELI'NA, (from *καμηλος*, a camel; because they are fond of it). See ERYSIMUM.

CAMERA'TIO. See CAMAROMA.

CA'MES, or CA'MET. See ARGENTUM.

CA'MINGA. See CANELLA ALBA.

CAM'NUS. A furnace and its chimney. In Ruilandus it signifies a bell.

CAM'SIA Fœ'TUS (from the Arabic term *kamisah*, an under garment). See CHORIUM.

CAMMARUS. The LOBSTER, or GRAY FISH; so named from the shape of its shell. See CANCER FLUVIATILIS.

CA'MMORUM, (quia homines *κακω κορω* perimat,) NIGHTSHADE; because if eaten it destroys in a deplorable manner. See CAMARUM.

CAMOT'ES I'NDICA. See BATTATAS HISPANICA.

CAMO'MILLA, corrupted from CHAMÆMELUM, which see.

CAMPA'NA. A BELL; so called because Paulinus, the bishop of Nola in Campania, first used bells for religious purposes. In chemistry it is a receptacle for the gas of sulphur, where it is concentrated and collected together into a fluid, the *oleum sulphuris per Campanam*, which is only the modern sulphuric acid.

CAMPA'NULÆ, (a dim. of *Campana*). See CERVICARIA.

CA'MPE, (from *καμπω*, to bend). A flexure or bending. It is also used for the ham, because it is the part usually bent; and for a joint, or an articulation.

CAMPECHE'NSE LI'GNUM; brought from the bay of Campeachy in America. LOGWOOD; also called *Acacia Zeylanica*, *lignum Camfescanum*, *saffian lignum*, *tsiam pangam*, *lignum Campechianum*, *Indicum montanum lignum*, *lignum tinctile Campech.* CAMPEACHY, BRASIL, or JAMAICA WOOD.

It is the wood of a prickley pod bearing tree, a native of Campeachy island. It is brought to Europe in large compact logs of a red colour. Its fruit resemble cloves in their quality. It is the *hæmatoxyton campechianum* Lin. Sp. Plant. 549. Nat. order *lomentaceæ*. HÆMATOXYLON, (from *αἷμα*, blood, and *ξύλον*, wood,) also called *erythroxyton*.

This wood, of which the tree is a native of Honduras, is chiefly brought for the dyers, but used medicinally as an astringent or corroborant. It is peculiarly efficacious in diarrhœas, and in the last stages of dysentery. When the obstructing causes are removed it restrains the discharge, without contracting the fibres like astringents: it sheaths acrimony, and its astringent taste is combined with a sweetish mucilaginous one; strengthens the bowels, and perhaps the general habit. It is an agreeable medicine, being free from any thing disgusting to the taste, and almost void of smell.

The London college direct a pound of the shavings of logwood to be boiled in a gallon of distilled water to one half; this must be repeated four times. The fluids must be mixed, strained, and boiled to a proper consistence. The shavings are ordered to prevent it from being mixed with the Jamaica, or other cheaper woods; which might be the case if bought in powder. The dose is from ℥ i. to ʒ ss. repeated according to the urgency of the symptoms.

Rectified spirit of wine takes up more from this wood than water; therefore it is better to digest its powder in as much spirit as will cover it three or four fingers' breadth above its surface, then boil the residuum in water, as directed above. The watery menstrua are first evaporated to the consistence of honey, then the spirituous extract, formed by drawing off the spirit, is mixed with it.

The decoction of logwood is made by boiling three ounces of powdered logwood in four pints of water to two, at the end of which two drachms of cinnamon are added, and boiled together a few minutes. When cool the decoction is strained.

Both the extract and decoction are agreeable, mild, and safe, when stronger astringents are less advisable; and may be used with equal safety whether a fever

attends or not. These preparations make the stools and urine appear like blood. The decoction may be taken in the quantity of four ounces three or four times a day.

The preparations of this wood are chiefly held in esteem for their astringency, and may be given safely in fluxes and at the close of dysentery; but in the beginning they are hurtful. Cullen.

When flatulencies attend in diarrhœas and dysenteries, a few grains of the cortex elutheriæ is a proper addition to each dose of the above extract or decoction. See Lewis's Mat. Med. Neumann's Chemical Works, and Cullen's Mat. Med.

CAMPHO'RA, (from the Arabic term *caphura*). CAMPHOR; called also *caf*, *cafar*, *ligatura veneris*, *caphora*; *capur*, *alkosor*, *altefor*; CAMPHOR. It is a solid concrete, chiefly obtained from the woody part of some trees which are met with in the island of Borneo in the East Indies, and in Japan; it is only from the latter that it is brought into Europe. The Indians have a species, which they distil from the roots of the true cinnamon tree, that they call *baros*; (see CINNAMOMUM;) and also a species which separates from the *camphoræ oleum* on re-distilling it. It sometimes oozes from the bark of the root of the cinnamon tree in the form of oily drops, which insensibly concrete into white grains: these are called *caphura baros Indorum*. In the state camphor is extracted from the roots of the camphor tree, it is named *camphora rudis*. The Japanese cut the wood of the roots and branches in small pieces, and boil them with water in an iron pot. The camphor sublimes in a clay head in friable, granulated masses of a yellowish or dark colour, like the coarsest sugar, mixed with straw, &c. The Chinese macerate the branches in water, and then place them in a pot over the fire: the contents are stirred with a willow rod, on which the camphor concretes. It is obtained chiefly from the *laurus camphora* Lin. Sp. Plant. 528. Nat. order *oleraceæ*. In smaller quantities it is obtained from several other vegetables. The thyme, the rosemary, the peppermint, the root of the canella, many of the labiated plants, and the whole tribe of the laurels, afford it.

As first sublimed or distilled from the wood, it is of a brownish colour, and composed of semi-pellucid grains, mixed with some impure matter; in this state it is imported by the Dutch, then called unpurified camphor. It is purified by a second sublimation, but after a manner only known to themselves, except the Venetians, who formerly were the only refiners of it. Bomare discovered in Holland that it was purified by sublimation. The last process in the management is so contrived, that the head of the subliming glass is kept warm enough to make the camphor run together into a mass of its own figure, in which form it is brought into the shops. Dr. Lewis says, that it may be purified in sp. vin. rect. by solution, and recovered from the spirit by distillation, the spirit all rising before the camphor; and after this it may be formed into loaves by fusion, with a gentle heat, in a close vessel.

The ancient Greeks do not mention camphor: it was first used in medicine by the Arabians.

Camphor is a vegetable concrete, white, semitransparent, brittle, of a shining fracture, and of a crys-

talline texture, unctuous to the touch, with a fragrant smell, somewhat like that of rosemary, and a bitter, aromatic, pungent taste, accompanied with a sense of coolness on the tongue: it is volatile like essential oils, but without their acrimony; it also differs both from them and from the sebaceous oils, in suffering no sensible alteration from long keeping, in being totally volatile in a warm air, without any change or separation of its parts, and subliming unaltered in the heat of boiling water. It is lighter than water, burns in it without receiving any empyreumatic impressions, nor is it decomposed by any degree of fire to which it can be exposed in close vessels, though readily combustible in the open air. It combines with concentrated vitriolic, nitric, and acetic acids, rectified spirit of wine, oils, resins, balsams, alcohol, and æther. Of resins, balsams, and oils, it considerably diminishes the consistence. It does not dissolve, except in a very small proportion, and by the assistance of sugar, in water, in the weaker acids, or alkaline liquors. It melts into an oily appearance with a less degree of heat than that of boiling water; laid on a red hot iron it totally evaporates in a bright white flame and copious fumes, which, condensing, form a soot.

As camphor is found in so many different vegetables, it has been generally recognised as a vegetable principle. It contains an acid united with an oil, and the former may be separated by means of nitric acid. In the best camphor some of the essential oil is separated, and the jets of this oil occasion the peculiar motions of the camphor when swimming in water, described by Prevost and Venturi in the *Annales de Chimie*, vol. xix.

Camphor is known to be good, if, when it is put upon hot bread, it turns moist; if it becomes dry it is adulterated: it should be kept close in a bottle or a bladder, not to prevent it from losing its quality, but to preserve the whole of it from being lost by evaporation.

As camphor is so useful a medicine, it is necessary to examine its effects on the human machine in the clearest point of view. The first question is, whether its power is of a stimulant or sedative nature? Dr. Cullen seems clearly to have proved the last when taken into the stomach: externally it is certainly stimulant, for when taken into the mouth it has an acrid taste, and, though by its evaporation it excites a sense of cold air, what remains is a feeling of heat in the mouth and fauces. When taken into the stomach it often occasions pain and uneasiness, which Dr. Cullen imputes to the action of the acrimony upon the upper orifice. When applied to any ulcerated part, it perceptibly irritates and inflames. When thrown into the stomach of brute animals, it operates there by its effluvia; for though it has produced considerable effects on the body, neither the bulk nor weight is found sensibly diminished; hence he concludes the operations have been upon the nerves of the stomach, and to be entirely that of a sedative power. The sudden death of many animals occasioned by it, as experimentally proved, show still more evidently its sedative effects on the sensorium, destroying the mobility of the nervous power, and extinguishing the vital principle. Camphor first operates by inducing stupor and sleep, and the different symptoms of delirium; convulsions soon follow, and are a part of the same series of sedative effects. It evidently

shows no stimulant power on the sanguiferous system; for the pulse, where it has been observed, has been slower than before its effects took place by ten strokes in a minute. It is in general also softer and fuller, and a gentle diaphoresis is excited on the skin.

As camphor then seems to repress inordinate or irregular actions in the sanguiferous and nervous systems, while without any very striking or perceptible stimulus it determines to the skin, we may expect to find it highly useful in those affections where the action of either system is disturbed. If, however, we were to judge from its effects in diseases, we should pronounce it to be rather a stimulant than a sedative antispasmodic; since, when the actions are irregular and excessive, it requires more caution, and some additions of a refrigerant nature. No stimuli, on the contrary, are apparently required when the irregularity is attended with defective energy. It has been long since employed in *inflammatory fevers*, particularly when attended with delirium; but, in this state, the addition of nitre has generally been found necessary. When the delirium is violent, the doses which may be given, after due evacuations have been procured, are considerable; but, in general, an equal dose of nitre is necessary. This medicine is more convenient, as in the state which connects the more inflammatory with the lower or more putrid periods of the disease it is well adapted to each, if, on the one side, the nitre is omitted, and on the other, cordials are avoided. In the irregular delirium of the *nervous* and *putrid* fever it is highly useful; and while at any period its effects are assisted by the antimonial powder, so in these it may be advantageously combined with the aromatic confection, or, in a later stage, with volatile alkali. In short, we know no medicine that, with different additions, is so well adapted to every period of fever: it is soothing, calming, and composing. It prevents opium from producing irregular action in the brain; it prevents bark from inducing stricture on the skin; and stimulants from exciting a dry and uncomfortable heat. In the *lowest pestilential fevers* it is said to act as a cordial: in fact, it relieves the internal accumulations by its tendency to the surface, and seems to give strength when it only takes off oppression. These are its effects, not collected from books, but from experience; not suggested by theoretical speculations, but from attentive observation at the sick bed. Yet camphor has been said to be useless; an opinion which must be the result of prejudice, since it has been offered by those not without discernment, not without experience.

From the same train of reasoning we might suppose it highly useful in inflammatory or putrid sore throats. It has undoubtedly been found so, but the topical stimulus in the first instance has occasioned it to be swallowed with difficulty; and in the second, the necessity of giving the most active tonics and stimulants in the largest doses that can be taken, has often precluded the use of camphor. Yet it has been employed with success, though, for the reasons just assigned, we cannot speak of it from any very extensive experience.

If we pursue *inflammations* to the chest, we shall still find it an useful auxiliary. In *pleurisy* we seldom want its aid; and in the earlier stages of *peripneumony* the most active refrigerants are necessary. Yet, when the excess of inflammation is diminished, when the skin

remains dry, and expectoration does not come on, camphor, with antimonials, is highly useful. Common practice prefers, as we have formerly said, the kermes mineral, perhaps with reason; for should it not act as an expectorant, it will not so readily prove laxative; an effect always to be dreaded in peripneumony, as it checks expectoration. In the *putrid peripneumony*, camphor is the chief remedy. Though this disease is uncommon, it has been the author's fortune to witness four extensive epidemics of this kind; and camphor was among the most generally useful remedies.

We find little room for this medicine in *gastritis* or *enteritis*; but in the *peritonitis puerperarum* it is highly beneficial. This inflammation is not, however, confined to the puerperal state: we have often seen it, with no very dissimilar symptoms, in each sex, unconnected with parturition; and have found the camphor equally useful. In *inflammations of the kidneys and bladder* it seems a very efficacious medicine; yet chiefly applicable to that chronic inflammation of the neck of the bladder which often takes place from acrimony, or sometimes from abraded mucus. On the bladder and the genital system its sedative power is considerable, without the slightest mixture of stimulus; and, not to return again to the subject, we may remark, that in that weakened, irritable state of the genital powers, from excessive or unnatural indulgencies, it is essentially useful. In inflammations of the joints it has been commended, particularly in *gout* and *rheumatism*; yet we know of no very decided instances of its efficacy. In *inflammatory rheumatism*, with nitre and antimonials, it may be useful.

In the *exanthemata*, camphor is a medicine of singular utility. In *confluent small pox*, and particularly in repressed eruptions, it is peculiarly useful from its determination to the skin, without any injurious stimulus. In *scarlatina*, that equivocal disease, which, with the most violent external heat, is often putrid, it is equally advantageous: and, in *plague*, it has been highly extolled by those who have had more numerous opportunities of observing its effects than have been offered to us. In the *putrid measles* we should suppose it, from analogy, to be useful; but we recollect no instance of its employment in this disease, and it has never occurred to us.

We have said, that, with its power of diminishing irregular action, it leans rather to the side of a stimulant than a sedative power. Thus, in *mania*, where it has been employed with success, it is necessary to add nitre or the acetous acid. In convulsive disorders it is seldom trusted alone, but it has been advantageously joined with the metallic tonics. In *convulsive asthma* it has not been often employed; and the stimulus of its oil on the cardia has often rendered it inconvenient in *hysteria*. United, however, with the warm gums, it has been, in our hands, very useful.

When joined to other medicines, it adds to their efficacy, or corrects the inconveniences they might otherwise produce. Thus, in fevers, as we have said, it greatly assists the action of opium: it promotes the solution of gum resins, resins, and oil. By this power it may probably mitigate the acrimony of drastic purgatives, a quality assigned to it by many authors. By the same effect it assists the absorption of mercurial ointment; and sometimes seems to render it, by ex-

ternal friction, an useful antispasmodic. It has been said to mitigate its action; but this is probably unfounded. Camphor has also been supposed to correct the inconvenient stimulus of cantharides; yet we suspect that it rather, by its sedative power, relieves the inflammation they excite. When united with them in the blistering plaster it seems not to prevent strangury.

It has been said, by a French author, that camphor may be given in a clyster, in a dose of two drachms, in inflammations, or other irritations of the bladder or uterus. We once injected a drachm, and at another time, half that quantity, but from each an alarming coma was produced. The patients were, indeed, relieved; but at the expense of such anxiety, that we have never dared to repeat the practice.

Externally applied, it has been useful, in very small proportions in ophthalmia; and in external tumours, united with spirit of wine. In this form, also, it has been used with fomentations to gangrened parts with success.

The dose of camphor has been variously directed. It has been said that it should either be given in large doses not under twenty grains; or if in smaller, that they must be repeated at short intervals, should any sensible effects be expected. This, however, is too violent. In fevers, such large doses would be injurious from too great irritation, and we can seldom venture above six or eight grains. In nervous disorders this dose may be doubled: and in mania, twenty grains will not be too much. It may be divided and rubbed with nitre or sugar, and a few drops of spirits of wine; or united with mucilage of gum arabic, the camphor previously dissolved in a little spirit of wine, or expressed oil. Camphor, mixed with equal quantity of myrrh, makes an uniform solution in aqueous fluids; and this is the best mode of giving camphor in a liquid form, where myrrh may not be thought an improper combination with respect to the intent which we wish to produce. With the gum pills it readily unites, and it may be also formed into a convenient mass with the conserve of hips or stiff mucilage. This conserve most effectually covers it, if the form of a bolus is preferred.

An imprudent dose of camphor produces coldness of the extremities, vertigo, a small weak pulse, drowsiness, uneasiness about the precordia: but these effects are relieved by an emetic, followed with small doses of vinegar or other vegetable acids; and sometimes by mucilaginous drinks.

The camphorated emulsion may be prepared by adding a drachm of camphor to a pint of the almond emulsion, now called *lac amygdalæ*, ALMOND MILK; to mix the camphor, it will be necessary to use an additional quantity of the mucilage of gum arabic: a large spoonful, or more, may be given every two hours. Nitre, or acids, may be added, as the occasion may require. In the camphorated julep, little more than the smell of camphor is retained. The dose, in its best state, does not exceed a grain and a half.

The London college direct the following preparation of the *camphorated mixture*.

Take of camphor one drachm; rectified spirit of wine, ten drops; of double refined sugar, half an ounce; of boiling distilled water, a pint. Rub the camphor first with the rectified spirit, then with the sugar; lastly, add the water by degrees, and strain the mixture. This

is better made by mixing the *camphor* with double its quantity of gum arabic, for thus it is less apt to irritate the stomach; a large spoonful contains about a grain of camphor. Vinegar may be added instead of water; as it renders the camphor more agreeable to the stomach, improves its antiseptic power, and renders it, according to Mr. Parteger, more successful in mania.

The emulsion and the mixture of camphor are useful in low and putrid disorders, being, in these cases, the lightest and best cordials, especially for women or feeble men affected with spasmodic symptoms; and this effect shows, that the medicine may be useful in the smallest doses.

The London college also order the following *camphorated spirit* for external uses:

Take of camphor, four ounces; of rectified spirit of wine, a quart; mix them so that the camphor may be dissolved. This is often successful in removing pains, inflammations, numbness, or palsy, by rubbing the part affected with it. An ounce of camphor will dissolve in an equal quantity of spirit; and in these solutions it does not evaporate, for the spirit must all be evaporated before the camphor will exhale.

The *spiritus camphoræ tartarisatus*, is made by mixing equal parts of camphor and salt of tartar in a proper quantity of proof spirit, and drawing off one half. But this preparation does not possess any advantages above the sp. *camphoratus*.

The college of London used to add ʒi. of camphor to lb i. of the white ointment, and called it ung. alb. *camphoratus*; but have now rejected it, though it is esteemed as cooling, emollient, and discutient, and useful against cutaneous heats, tettery, or serpiginous eruptions.

Different preparations are called oils of camphor, several of which may be seen in Neumann's Chemical Works, and other writers; but they do not appear to possess any peculiar advantage above the crude camphor.

CAMP'HORÆ LINIMENTUM AMMONIATUM. See AMMONIA.

CAMP'HORÆ ELIX. HARTMANNI, i. e. *Spt. Camphoræ cum pauxillo croci Anglicani*.

CAMP'HORÆ FLORES. The subtle substance which first ascends in subliming camphor.

CAMP'HORÆ FLORES COMP. The compound flowers of camphor, made by subliming eight parts of camphor with one of the flowers of benjamin.

CAMP'HORÆ O'LEUM. See CINNAMOMUM.

CAMP'HORÆ SMA, (from *camphora*, so called from its smell). See MELISSA TURCICA.

CAMP'HORATA, (from *camphora*, so called because it resembles it in smell). STINKING GROUND FINE, called also CHAMÆPEUCE, and *camphorata hirsuta*. *Camphorosma Monspeliaca* Lin. Sp. Pl. 178. It is a low plant, a native of the warmer parts of Europe, smelling like camphor, but more disagreeable. It is much esteemed in fomentations against pain, and commended in gouty complaints. Miller's Bott. Off.

CAMP'HORATS, (from *camphora*). CAMPHORATS. Salts formed by the union of the camphoric acid with different bases.

CAMP'HORATUM O'LEUM. A mixture of olive oil, two parts, with one of camphor: of use in inflammatory swellings of the throat, if mixed with a proper cataplasm and applied to it. In ascites, when the abdomen is much distended, if rubbed on

freely every night and morning, it is supposed to be useful.

See Neumann's Chemical Works, Lewis's Mat. Med. Alexander's Exper. Essays, Rieger and Hoffman on *Camphor*.

CAMP'HORICUM A'CIDUM. CAMPHORIC ACID is produced by distilling the nitric acid, six or eight times, from camphor. It is a crystallized salt, which reddens syrup of violets and the tincture of turnsole; of a bitter taste, and differing from the oxalic acid in not precipitating lime from the muriatic acid.

CA'MPSIN. The Egyptian name for the south wind. See ÆTESIÆ.

CA'MPULUM, (from *καμπω*, to twist about). A distortion of the eye lids, or other parts.

CA'NABIL. See ERETRIA.

CANABINA AQUA'TICA. See BIDENS.

CA'NABIS I'NDICA and PEREGRINA, (*kanaba*, from *kanah*, to move). See BANGUE and CANNABIS.

CANADELLA. See CHANNA.

CANADENSE BA'LSAMUM. See BALSAMUM and ABIES.

CANALICULUS, vel CANALIS ARTERIOSUS. Dim. of Canalis. See ARTERIOSUS DUCTUS.

CANA'LIS, (from *canna*, a reed). A CANAL. It is also a round hollow instrument for embracing and holding a broken limb. Hippocrates speaks of its use, and Scultetus represents different sorts in his *Armentarium*, part. i. tab. 23. According to Gorræus, *canalis* signifies the hollow in the spine, which contains the medulla.

CANA'LES SEMICIRCULA'RES. The *semicircular canals* of the ear.

They are three in number, one superior and perpendicular, one posterior and perpendicular, and one horizontal; their size is nearly the same, but generally the superior perpendicular is the largest. They begin in the vestibulum, wind round the bone, and terminate in the vestibulum again: each at its origin has a separate orifice, but the two perpendiculars meet and return into the vestibulum by one common orifice. That these ducts contribute to hearing, appears from their being found in birds and fishes, though the cochlea is not found in either.

CANA'LIS SEMIS. PETROS. The BONY HALF CANAL. See AUDITUS.

CANALIS VENO'SUS. The vein of the funis umbilicalis proceeds from the placenta to the navel of the child, and thence to the vena porta, with which it communicates by its main trunk, where there is a canal, which goes to the vena cava hepatica. It is called canalis, and ductus venosus; it runs between the lobulus Spigelii, and the left or small lobe of the liver. This duct enters the vena cava hepatica of the left side, just where it pierces the great trunk of the vena cava inferior.

CANA'NGÆ O'LEUM. (Indian.) Hoffman mentions this oil as being scarce, and brought from India, adding that it is distilled from the flowers of the lime tree. It is in reality from those of the *uvaria* Lin. Sp. Pl. 756. The species *u. aromatica* is not found in his system. See Hoffman's Obs. Physico Chim. and in his Med. Rat. Syst. vol. i. § ii. cap. 6.

CAN'CAMUM GRÆCO'RUM. See COURBARI.

**CANCE'LLUS**, (dim. of *cancer*, a crab). The **WRONG HEIR**, also called *Bernhardus eremita*, *cancer in testes degens*.

It is a small species of cray fish, which the French call **BERNARD THE HERMIT**, because it shuns others, and retires into the first shell it meets with. It is found in the slime near the rocks, but commonly in a shell of a conic figure, and as large as a nut. There is a larger species in the American islands: it is three or four inches long. They call it the **SOLDIER**, because it fortifies itself in a shell which is not its own. Father Du Tertres says, half its body is like a grasshopper.

When hung in the sun they dissolve into a kind of oil, which is supposed to cure rheumatism if rubbed on the part.

**CA'NCER**. The **CRAB**, (*καρκινος*, from *καρχνος*, rough, because of the roughness and sharpness of its claws. *Cancer* in Latin corresponds with *καρκινος*, the *ἀσινκος*, or the *καρχμαρος* of the Greeks, and to the *crab* in the English).

**CANCER MARI'NUS**, (from *mare*, the sea). Is that called the **SEA CRAB**; named also *pagurus*, *cancer marinas* Lin.

**CANCER FLUVIA'TILIS**, (from *fluvius*, a river). The **RIVER CRAB**, or **CRAY FISH**; *cammarus* and *gammarus*; *cancer astacus* Lin. See **ASTACUS MARINUS**.

The black tips of the claw of *sea crabs* are levigated and used as an absorbent under the name of *pulv. è chel. cancerorum ppt.* The London college direct a compound powder, made with *crabs'* claws, red coral, and chalk; but they all consist of the same calcareous animal earth.

*Pulvis è chélis canceròrum compòsitus*, is made by uniting a pound of the tips of *crabs'* claws prepared to three ounces of chalk, and as much red coral.

The composition has been considered to be inelegant, for the *chelæ cancerorum* consists of a calcareous earth, part of which is combined with the phosphoric acid and glutinous matter; the *corallium rubrum* contains the same, and these are mixed with chalk, a somewhat more pure calcareous earth. The preparation is therefore far from a pure absorbent. The *creta* and *testæ ostreorum* will better supply the place; and if calcareous earth is desired to be combined with phosphoric acid, it may be found in the *cornu cervi ustum*. Observations on the Sp. Alterum Pharmacop. Londinensis, 1788.

The college of Edinburgh in a former edition directed the following preparation called *pulvis testaceus compòsitus*.

Take of oyster shells prepared, one pound; and of white chalk prepared, half a pound. Mix.

The use of all the absorbent earths, and preparations of shells, is to absorb acidities in the *primæ viæ*; and this prescription from the Edinburgh dispensatory is equally valuable as a medicine with any other preparation of the kind, however attended with pompous epithets. If they meet with no acid to dissolve them, they should be accompanied by gentle purges. They are suspected of promoting putrefaction, but produce this effect only by absorbing acid, as we have already explained. If oyster shells form with a very weak acid a mucilage, like that which lines the inner surface of the stomach, bladder, and blood vessels, this mucilage

may supply in some measure the want of the natural mucus when abraded.

See Lewis's *Materia Medica*, and Neumann's *Chemical Works*.

**CANCER**, (from *καρκινος*, a crab). By the term *cancer*, the Roman writers understood what the Greeks called gangrene and *sphacelus*; but the disease which is now called *cancer* is what the Greeks and Romans meant by *carcinoma* and *carcinos*. It is called also *lufus*, because it eats away the flesh like a wolf. See Celsus, lib. v. cap. xxviii.

Galen observes, that, as the *crab* is furnished with claws on both sides of its body, so in the *carcinoma*, or *carcinos*, the veins, which are extended from the tumour, represent with it a figure like a *crab*; hence is the disease called **CANCER**. Boerhaave adds, that if the stagnating matter of a *scirrhus* is put in motion, so as to inflame the vessels situated in its margin, it becomes malignant, and then is called a cancer.

With Hippocrates we may, perhaps, most properly consider all the species as comprised in the occult and open cancer. A cancer then is, according to P. Ægineta, a hard unequal tumour, with or without an ulcer. Hippocrates calls that an occult cancer that is not yet burst; and that an open one which is ulcerated.

Mr. Pearson says, when a malignant *scirrhus*, or a warty excrescence, hath proceeded to a period of ulceration, attended with a constant sense of ardent and occasionally shooting pains, is irregular in its figure, and presents an unequal surface; if it discharges sordid, sanious, or fetid matter; if the edges of the sore be thick, indurated, and often exquisitely painful, sometimes inverted, at other times retorted, and exhibit a serrated appearance; and should the ulcer in its progress be frequently attended with hæmorrhage, in consequence of the erosion of blood vessels; there will be little hazard of mistake in calling it a cancerous ulcer.

Dr. Cullen places this genus of disease in the class *locales* and order *tumores*. He defines it a painful *scirrhus* tumour, terminating in a fatal ulcer.

Any part of the body may be the seat of this disorder, though a gland is generally, if not constantly, its immediate situation. The obstruction is in the minute vessels, and the adjacent parts are affected in consequence.

"It is probable," according to Mr. Pearson, "that any gland in the living body may be the seat of a cancerous disease; but it appears more frequently as an idiopathic affection in those glands that form the several secretions, than in the absorbent glands; and of the secreting organs, those that separate the fluids, which are to be employed in the animal economy, suffer much oftener than the glands which secrete the excrementitious part of the blood. Indeed it may be doubted whether an absorbent gland ever be the primary seat of a true *scirrhus*. Daily experience evinces that these glands may suffer contamination from their connection with a cancerous part; but, under such circumstances, this morbid alteration being the effect of a disease in that neighbourhood, it ought to be regarded as a secondary and consequent affection. I never yet met with an unequivocal proof of a primary *scirrhus* in an **ABSORBENT GLAND**; and if a larger experience shall confirm this observation, and establish it as a general rule, it will afford a material assistance in forming the diag-

nosis of this disease. The general term *scirrhus* has been applied, with too little discrimination, to indurated tumours of the lymphatic glands. When these appendages of the absorbent system enlarge in the early part of life, the disease is commonly treated as strumous; but as a similar alteration of these parts may, and often does, occur at a more advanced period, there ought to be some very good reason for ascribing malignity to one rather than the other. In old people the tumour is indeed often larger, more indurated, and less tractable, than in children; but when the alteration originated in the lymphatic glands, it will very rarely be found to possess any thing cancerous in its nature." However, in men, a *cancer* most frequently seizes the tongue, mouth, or penis; in women, the breasts or the uterus, particularly about the cessation of their periodical discharges; and in children, the eyes. Sometimes at the breast there is a hard and unequal tumour, attended with pain, which is not quite constant, and a burning heat much like what happens in cancer, whence it is called *ZARUTHAN*, a *spurious cancer*.

Celibacy, as well as the cessation of the menses, conduces to the production of cancers in women, and consequently antiquated maids are the more subject to them: next are those mothers who have not suckled their children; then follow women who are past child bearing; and the least so are men, and those women who have borne children and nursed them with their own milk. Hollerius observes, that girls are subject to glandular tumours whose menstrual discharges are scanty.

A hard unequal tumour that is indolent, and without any discoloration in the skin, is called a *SCIRRHUS*; but when an itching is perceived in it, which is followed by a pricking, shooting, or lancinating pain, and a change of colour in the skin, it is usually denominated a *CANCER*. It generally is small in the beginning, and increases gradually; but though the skin changes to a red or livid appearance, and the state of the tumour from an indolent to a painful one, it is sometimes very difficult to say when the *scirrhus* really becomes a cancer, the progress being quick or slow, according to concurring causes. When the tumour is attended with a peculiar kind of burning, shooting pains, and the skin hath acquired the dusky purple or livid hue, it may then be deemed the malignant *scirrhus*, or confirmed cancer. Mr. Pearson further adds, when thus far advanced in women's breasts, the tumour sometimes increases speedily to a great size, having a knotty unequal surface, more glands becoming obstructed, the nipple sinks in, turgid veins are conspicuous, ramifying around, and resembling a crab's claws. These are the characteristics of an occult cancer on the external parts; and we may suspect the existence of one internally when such pain and heat as hath been described succeed in parts where the patient hath before been sensible of a weight and pressure, attended with obtuse pain. A cancerous tumour never melts down in suppuration like an inflammatory one; but when it is ready to break open, especially in the breast, it generally becomes prominent in some minute point, attended with an increase of the peculiar kind of burning, shooting pain, felt before at intervals, in a less degree, and deeper in the body of the gland. In the prominent part of the tumour, in this

state, a corroding ichor sometimes transudes through the skin, soon forming an ulcer; at other times a considerable quantity of a thin lymphatic fluid, tinged with blood from eroded vessels, is found on it. Ulcers of the cancerous nature discharge a thin, fetid, acrid sanies, which corrodes the parts, having thick dark coloured retorted lips; and fungous excrescences frequently rise from these ulcers, notwithstanding the corrosiveness of the discharge. In this state they are often attended with excruciating, pungent, lancinating, burning pains, and sometimes with bleeding.

Though a *scirrhus* may truly be deemed a cancer as soon as pain is perceived in it, yet every painful tumour is not a cancer; nor is it always easy to say whether a cancer is the disorder or not: irregular hard lumps may be perceived in the breast; but, on examining the other breast, where no uneasiness is perceived, the same kind of tumours are sometimes found, which renders the diagnostic uncertain. Yet, in every case, after the cessation of catamenia, hard unequal tumours in the breast are suspicious; nor, though without pain, are they to be supposed indolent or innoxious. We think, with Mr. Pearson, that the absorbent glands are seldom or never the seat of cancers; and, could we distinguish in the breast these from the true secretory organs, our distinction might be more correct. Lymphatic glands are, however, found in the breast, though not numerous. A few distinct tumours, traced in a chain to the axilla, are perhaps lymphatic glands, and will never become cancerous; yet no prudent physician will offer such a decided opinion even to the patient's friends.

The nature of cancer is unknown. It has long been disputed, whether it was a general disease, a portion of the fluids, determined by different causes to the affected part, or whether any accident to the organ diseased altered its former habits, so as to produce a poisonous corrosive fluid instead of the usual salutary one. Much serious argument, and, we may add, much idle jargon, have been employed on both sides. We shall endeavour, at least, to place the question on its proper footing; and, though we may not greatly elucidate the subject, yet we trust we may be able to direct the arguments and observations more conclusively in future.

If cancer were a general disease, we might expect it to be distinguished by a determined appearance in the look, or decided marks in the constitution: it might be sometimes hereditary, or perhaps contagious. We suspect that there are striking appearances in the complexion; for we have found cancers more frequent in the dark cadaverous complexions than in the fairer kind. The complexion we mean is distinct from the darkness of the atrabilious or melancholic habits: a blue tint seems mixed with the brown, and is chiefly conspicuous under the eyes, or in the parts usually fair. This may, perhaps, be a refinement without foundation, but we think we have often observed it. There is certainly no constitutional symptom by which it can be predicted, if, in women, a scanty and a dark coloured catamenial discharge be not a prognostic of the future disease. We would not, however, disseminate alarm; and can truly add, that in such cases the woman is by no means peculiarly liable to cancer; yet cancer sometimes follows the cessation of such a discharge. Cancer has certainly been traced in females of the same family; and those who have escaped, suf-

fer from irregular anomalous pains, and different, often unaccountable, complaints. That cancer is contagious we have not the slightest reason to believe: we mean from effluvia; for the matter inserted under the skin, or touched with the tongue, *has been said* to produce the complaint.

Such arguments will scarcely establish the general nature of the disease; but others, drawn from its history, may be more decisive. It is not uncommon to find a cancerous sore heal by the efforts of nature only; and it is equally common to find soon afterwards, diseases in different organs, as if some morbid matter had been deposited on them. We have seen an enteritis, with peculiar symptoms, follow; and we have, in more than one instance, found an apoplectic attack at no great distance. Fixed pains in the limbs, and an unconquerable sciatica, have been frequent followers. It may be asked, do cancers so often heal as to give such an extent of observation? We have seen six instances of this kind, and one or other complaint has followed: in one an apoplectic attack occurred twice, and the last was fatal. It is with pain we add another source of similar observations, we mean the extirpation of a cancerous tumour. Were the disease local only, the operation should be expected always to succeed; and indeed in the early stages, in tumours which have yet assumed no very decided character, which are moveable, and the constitution otherwise sound, no return is found often to take place. In other circumstances, however, a return is common. The blood then may be at last affected; and, if so, why not at first? Why should not a blow in the breast in every instance produce a cancer, if it does in any, but that the constitution is previously diseased? Thus a blow on the knee will produce a white swelling; but ten thousand children receive blows on the knees, and unless a scrofulous disposition should concur, no inconvenience arises.

If, however, the matter is generated in the constitution and determined to a gland; if, again absorbed and carried to another organ, various questions will arise.—Is the whole deposited on the part first affected? Does the poison possess an assimilatory power, or when one part is diseased, is it the focus in which all the matter is concentrated? We find it is fashionable to deny cancer to be a general disorder, and complaints, previous or subsequent to it, are explained away; yet, while we do not triumphantly urge difficulties on the opposite side, we trust that they will not be pressed against what we suggest only as the more probable opinion. We will, however, explain our own ideas of the state of the poison in this complaint.

In all cases of cancer, either a morbid matter seems to float in the constitution, or the fluids are in a depraved state, from which such a matter may be derived. The last is seemingly more often the case. When, then, a cause of inflammation supervenes; when a wound or a bruise occasions the necessity of a discharge; this wound will assume what is styled a bad aspect, any suppuration will become cancerous. In fact, what might be a mild, salutary suppuration in a healthy constitution, will thus be of an opposite kind. While the sore continues open, there is not always an absorption; for in the irritable, inflammatory state of ulcers from specific contagion, we see few, if any, in-

stances of the fluids being absorbed. Yet in cancer, after some time, we know that absorption does take place; and, when inflammation abates, and the sore is healed, we have every reason to think that the impediment to the action of the lymphatics is removed. The matter then, thus accumulated, and thus changed, may be taken up and again deposited.

If this reasoning be admitted, and we *know* that it will meet very accurately all the phenomena, we shall find that the fomes in the blood is not really cancerous, but capable of becoming so in consequence of its being subject to the process of suppuration in the injured part. Supposing, therefore, the injured part to be removed before suppuration has contributed to the change, the patient may remain safe; and supposing these depraved fluids not again to be brought to a suppurated gland, the disease may not recur. The whole of this reasoning may be pronounced theoretical. Admitted: it will, however, explain every appearance; it will elucidate every part of the best founded practical conduct. Let it be for a moment supposed fallacious; it will afford a clue to connect numerous facts and discordant directions.

But what, it may be asked, is this depraved state of the blood which will produce such a destructive enemy? We can answer, that it is an excess of ammonia, with a more copious development of an ingredient in the animal fluids which we have so anxiously pointed out, sulphur. The discharge from cancer, Dr. Crawford has informed us, is an hepatised ammonia; and we find in no secreted fluid any ingredient that does not exist in the blood. Its component parts may be varied in form, in proportion, in consistence, and acrimony, but they are still the same; and this position, not hastily hazarded, we trust will be kept in the mind of our readers. It shall at a future period be developed.

In this reasoning we have laid a particular stress on the changes produced by suppurated glands: it was not without reason; but the explanation of the reason would lead us from the point. In fact, there are few instances of glands suppurating, as the surgeon style it, kindly. Suppuration chiefly takes place in the cellular substance; and, when the glandular parts are affected, whether conglobate or conglomerate, the wound does not heal readily. When, however, in a cancerous habit a tumour or a wound assumes a peculiarly unpleasant appearance, if the part is not glandular, the wound may either heal, or the whole be taken out, if accessible, with little danger of returning; and we think it a strong proof of what we have alleged, that, when not in a gland, but in the lip or nose, the operation generally succeeds: in fact, the peculiar matter is not further contaminated by the unkindly suppuration. We have spoken also of cancers chiefly as a female complaint. It is not their peculiar misfortune; but in them it chiefly attacks the glands; in men, other parts. In women the operation does not often succeed; in men it seldom fails.

We must not, however, rest so strongly on the system just stated, to neglect the sentiments of other authors. It is certainly, as we have said, the more general and the more fashionable opinion that cancers are local complaints. This idea has not, however, been expanded so as to meet all the appearances, unless by

referring it to putrid or scrofulous tumours, except by the pathologists of the school of Mr. Hunter, who have spoken of diseased, and, more lately, of acquired actions. We purposely omit the opinion of Mr. Adams, which we shall afterwards consider more at length.

If the idea of 'taking on diseased action,' be any thing more than saying that a part is diseased, it has not been explained. If it is no more, it says nothing: a cancerous mamma is a diseased mamma, and of course has taken on diseased action. A new step has, however, been lately added, and a part has been said to acquire new actions. Thus, when nature cannot unite a fracture by a bony callus, she supplies its place by a cartilaginous medium. When the coat of an artery is weakened, a lamina of bone supplies the defect; "and in scirrhus formations or changes, a marked and very extraordinary attempt is very frequently evinced to correct the deranged state of things, by reducing the whole into one insensible and homogeneous mass: and here, at the same time, is afforded the most direct evidence of the disease of cancer arising and depending on simple altered organisation only. The very source and supply of the disease is an assimilation of various and unequal structures, giving rise to dissimilar actions. What then could nature do better (when all her attempts have failed to restore an equilibrium of parts) than what she very often effects, viz. reducing the whole into a bony mass? Here all discordancy of action is at once destroyed, and an attempt at natural cure in scirrhus is clearly evinced, which shuts out the idea of a 'specific virus.' This attempt at natural cure is frequently exemplified in the examinations of true scirrhi, a progressive change into bone being often evident; in many, the centres are completely ossified. Such attempts have been still more successfully accomplished in the ovaria, these parts having often been found wholly converted into bone by the cancerous action. See Baillie's Morbid Anatomy.

"Confused, therefore, as the cancerous mass may appear, yet more of arrangement would seem to exist than one might at first be aware of. Such would appear to be evinced with respect to the membranous intersections, or septa, most commonly observed in scirrhi; as particularly noticed by Dr. Baillie.

"Query:—In the view of natural cure, may not these septa serve as a surface of extension for bony actions, similar to what we see in the formation of the bones of the head?" Young on Cancers, p. 51, &c.

We have thus selected the author's words, as we were apprehensive of mutilating or misunderstanding his reasoning. According then to this author, if any part is diseased, or, to come nearer the point, if any gland is obstructed so that its usual actions are disturbed, it acquires other actions; chiefly, as it should seem, to supply the deficiency, to obliterate the part, or to restore it to a healthy state.

If we were to examine the changes attributed to these acquired actions in the passage quoted, we should find a more ready mode of explaining them; nor should we require so recondite a foundation, as Mr. Young's fundamental axiom, that 'the essence of organic life is immutable.' We should not, however, object to this reasoning, were the terminations of cancer ossifications; or indeed were there any acquired actions which would restore the organisation of the parts, or compensate

for its injured functions: on the contrary, by cancer the part is indeed destroyed, but sound parts suffer, and life itself is lost. We perceive, also, no explanation of the phenomena of cancer in this system of acquired actions, and, of course, need not dwell on it. Mr. Young's work is the latest on this subject; but, in the same school we have found nothing more satisfactory. We agree, however, with him, that scrofula and cancer are distinct diseases.

The only other system which it is necessary to notice is that of Mr. Adams, who considers cancers as owing to animals of the hydatid kind. To find them penetrating all the intricate convolutions of minute arteries, is, at first view, a striking objection to this system; yet they appear in the liver, in the ovaria, and other organs, where the access is equally difficult. This subject, of course, we must resume when we speak of this animal, and can only add, that the cause is highly probable; and were the opinion we have offered no longer tenable, we should not hesitate to adopt that of Mr. Adams. A singular case of cancer, strongly corroborative of the disease arising from hydatids, occurs in Dr. Hamilton's Observations on Scrofulous Affections, with Remarks on Scirrhus, &c.

The parts usually affected by cancer are, the mammae of females, the uterus, the testes, the glans penis, the tongue, the stomach, cheeks, lips, and angles of the eyes. These are not always glandular parts; nor, though a cancer of these is a more dangerous disease, though extirpation more seldom succeeds, yet in a depraved state of the fluids, any organ may suffer if a cause of suppuration occurs. The ovaria are said to be affected with cancer: more commonly, however, they become scirrhus; or enlarged by hydatids, forming local encysted dropsy. Of the prostate gland, also, cancer is a rare complaint, though in advanced age this part often becomes scirrhus. The breasts of females are seldom cancerous before the cessation of the menstrual discharge, *for whatever may be the appearance, a MILK ABSCESS NEVER BECOMES A CANCER.* We have seen it continue beyond the period of the cessation of the catamenia without any bad consequences: it has healed at last.

It is not easy to say why the parts mentioned should be peculiarly subject to the disease. The cause has been referred to a complicated structure; but there is no such structure in the tongue, in the lips, in the angles of the eyes. The sexual parts are certainly most subject to the complaint. Is it that the circulation is slower; that congestion is more likely to happen; and that any accidental cause of inflammation may excite the action of the obstructed portion? In every view of the disease the same difficulties will recur.

Of the causes of cancers we can say little. In the stomach, the dram drinker has been supposed more liable to the disease; and in general what induces a depraved state of the fluids, as irregularity in diet, ebriety, a sedentary life, and confined air, predispose to it. Celibacy, as we have observed, seems to be a predisposing cause; and we have suspected that when marriage has taken place at a late period, the disposition to cancer has been accelerated.

The progress of cancer is various; in some cases rapid, in others slow. In almost every stage nature seems to attempt relief, and granulations occasionally

spring up, giving hopes of a cure, which are soon disappointed. The discharge is not highly putrid, but has a peculiar hepatic smell, sufficiently well known. The taste is said not to be acrimonious, but insipid and 'mawkish.'

A cure is rarely made but with the knife or caustic; when these methods of relief are not used, the treatment is only palliative. If the tumour firmly adheres to the subjacent part, it can neither be extirpated nor wasted away by a caustic: if it is moveable, it may generally be taken away, cautiously avoiding such blood vessels as would endanger life by being wounded. In general, the larger are more dangerous than the less, the painful than the indolent, and the ulcerated than the occult. When a breast is once scirrhus, it seldom continues long in a state that threatens a cancer without affecting the axillary glands, occasionally the other breast, or the uterus. When a cancer in any part is attended with a hardness of the adjacent glands, success hath rarely followed an attempt to cure. In habits not otherwise disordered, an occult cancer should not be exasperated by emollients, stimulating application, or intemperance, for then it may remain a long time without inconvenience; though at the cessation of the menses in women they will be exasperated. If then it can be conveniently done, it may be most proper to extirpate early.

The remedies employed in this disease have been various; and, though we cannot always boast of success, we can often arrest the progress of the complaint, and, without curing, can, for a series of years, render it harmless. Our former explanations will at least connect the remedies, and perhaps render their application more clear.

If, in a cachectic habit, a tumour is formed on any of the external parts mentioned, indolent, discoloured, and occasionally painful, we have reason to suspect the approach of cancer. If in the breast of women about the cessation of the menstrual discharge, should there be even no pain, danger is to be apprehended. This is perhaps the period for topical, refrigerant applications, for topical discharges, and for internal alterative medicines. Leeches should be repeatedly applied, the parts bathed with saturnine lotions, the diet limited to the mildest nutriment, and wine avoided. In short, at this period, every thing that can prevent or lessen inflammation should be employed, while the activity of the smaller vessels may be gently stimulated to prevent or relieve congestion. We combine the stimulant and relaxant power very successfully in the form of Plummer's pill, to which a slight opiate may be added, taking care that no constipation of the bowels should increase the heat. After a short period, the external applications may be more stimulating. The aqua ammoniæ acetatæ may supersede Goulard's lotion; a small proportion of mercurial ointment with camphor may be gently rubbed in, *around* rather than *upon* the tumour, or a mercurial plaster applied. At the same period, issues have been sometimes formed in distant parts, but we have had little experience of *their* utility; yet the measure certainly merits a trial.

Internal cancers, however, give no certain index of their existence till they are advanced much further. Yet, if in a cachectic state, there are irregular and dark discharges of blood from the vagina, shooting pains in

the lower part of the belly, a sense of weight on turning in bed sensibly felt to fall on the lower side; above all, if, on examination, the uterus feels heavy, the os teneæ hard, and with irregular projections; there can be little doubt of the cause. When the discharge becomes more decidedly of a cancerous nature, every doubt must be removed. Cancer in the vagina, an uncommon case, but of which we have seen an instance, can be easily felt: in the rectum also the distinction is not difficult. In the stomach it is very doubtful, and is seldom ascertained till after death. Yet, whenever cancer is suspected in the internal parts, if no discharge has yet taken place, the same plan of internal remedies may be followed.

A question will arise, whether this (we now allude to the state of external cancers in the early period) is the proper time for the celebrated decostruents, hemlock and arsenic? Were our own experience to guide us, we should say, that, in this state, we have found neither useful. Of the former we would speak with some hesitation. It seems to have been first given in a random trial, and continued from the confident promises of those who had apparently used it with success. Of the integrity of Van Swieten, Storck, and Colin, we would not insinuate the slightest suspicion; yet we know that those who are willing to believe in the powers of a medicine, will always find some facts apparently to support them. We dare not say that hemlock is of no use; but if called on for facts to justify any assertion in its favour, we should find them with difficulty. After these observations we need not return to this remedy, but shall only add, that the doses, gradually increased, of the extract, soon become a cold inert mass on the stomach. The seeds are more active in a smaller bulk; but, in whatever form it is given, it should be increased till it exerts some evident power on the general system, either by affecting the head or stomach with giddiness or nausea.

We may, indeed, be asked, by what links we connect the effects of the hemlock with the accounts we have given of the disease? We see no connection; but may observe, in general, that all the poisonous plants excite a commotion in the system, with a design probably of counteracting their deleterious effects. When this commotion is general and considerable, the obstructions of a diseased part may experience some salutary change. This is the case with the aconite, the foxglove, the hemlock, and the whole tribe; and the suspicion receives no inconsiderable support from this circumstance, that these medicines are only serviceable when raised to such a dose as to produce violent effects. Few practitioners will, probably, doubt that hemlock has done infinitely more mischief in supposed cancers, than it has done good in real ones.

It may be asked, also, to what period of the complaint the internal use of arsenic should be confined? We suspect it is not proper in this early stage: at a later period it certainly acts as a tonic, and a moderately gentle stimulant. We have seen, from its use, an extensive sore filled with the most healthy granulations, the complexion become clear, the appetite improved, and the general health increased. Unfortunately, these good effects have not been permanent. By increasing the dose, we have gained a little more, but at last every advantage was apparently lost.

We have been led, however, from our path, by pursuing the effects of remedies not adapted for the stage of the complaint we were considering. When an accidental tumour is excited to suppuration in a diseased habit, and the plans formerly mentioned neither discuss it nor prevent inflammation, the sore appears to arise from distinct points in the manner described, which soon unite, and form one large, foul, ragged ulcer, with retracted or inverted edges. This ulcer is painful and irritable; but the sedative applications do not then succeed, and moderately stimulant ones seem to relieve. In fact, the inflammation is of the erysipelatous kind, and requires warmer applications than truly phlegmonic sores. At this period, medicines, we fear, are useless. The arsenic, the hemlock, the aconite, the bella donna, with innumerable other poisonous plants, have had their supporters, but success has not procured many imitators. The carrot poultice was thought useful: it corrected the factor, but did no more. The carbonic acid air had its day of triumph in many different forms, but is no longer remembered. Hemlock has been used in fomentations and in tepid baths, in which the patient has been directed to sit for twenty minutes, at times with some apparent utility, but often without effect. Toads have been induced to suck the sore, and it has been said that they expire in agonies, while the appearance of the ulcer is meliorated. If this were, however, the case, the practice would not have been abandoned. We have witnessed the experiment, but it was at an age when our observations could scarcely be trusted. At this period, mercury is, we think, injurious; but arsenic, which unites a tonic with an inferior stimulating power, will often produce temporary benefit.

We have described the effects of arsenic given internally, as well as the disappointment which often followed its continued use. Another metallic tonic has been employed, it is said with some success, in cancers, viz. the ferrum ammoniacale, formerly the flores Martiales. With this remedy we have had little experience; but have reason to believe, that, like the arsenic, its advantages are temporary only. It is assisted by a tincture of iron, united probably with æther; but which is imitated, with sufficient advantage, by mixing the tinctura ferri muriati with an equal portion of spirit of wine.

Before we speak more fully of external and other remedies, we may mention one form of cancer which does not essentially differ from the usual appearances of the disease but in its very rapid increase. It has been called the *occult cancer*, probably because it was supposed to be a sudden deposition of matter before concealed. The swelling is rapid, and increases soon to an alarming size, with very considerable hardness. Whether this be a real deposition from the blood, or whether peculiar causes assist its rapid increase, is of little consequence to enquire, as the treatment is the same, and the success, though not greater, certainly not less.

When a tumour in any part has not ulcerated, when attended with little pain, and freely moveable, extirpation is an operation equally easy and successful. In parts apparently not glandular, as in the cheeks, the lips, the glans penis, &c. it very often succeeds completely. In the breast, the disease is more likely to return; yet, in the state just described, even this is not very common. The further we recede from it, the less

favourable is the prognostic. The first Monro gives, in the Medical Essays of Edinburgh, a very unfavourable statement of the operation; but Mr. Hill, of Dumfries, seems to have been more successful. It may be, indeed, remarked, that a large proportion of the cancers he extirpated were from the lips and other parts; those of the breast were not equally numerous.

When female timidity refuses to submit to the knife, a caustic has been proposed, and the substance chosen has been arsenic. We have already spoken of this substance and its preparations, but, by accident, omitted one very commonly employed, the magnes arsenicalis. The omission was the more singular, as it stood in our list of arsenical preparations, and we mentioned the plasters formed from it. The preparation was first described by Hollandus about the latter end of the fourteenth century, and afterwards by Crollius, Angelus Sala, and Vitalis. It is made by melting together arsenic, sulphur, and antimony. The preparation has been improved by Mr. Justamond, who used it as a caustic, under the name of arsenicum antimoniatum, and was prepared by melting two parts of antimony with one of arsenic. The sulphur of the antimony supplies a sufficient portion in this instance to lessen the virulence of the metal.

We think, however, that arsenic is improperly called a caustic. This acts by destroying the part to which it is applied. Arsenic, on the contrary, separates the sound from the diseased portion, not by any action on the part itself, but by exciting the powers of nature; and a caustic is added to it to destroy the integuments. The effect of arsenic may be very properly illustrated by what takes place in mortifications. When, by warm fomentations, stimulants, and tonics, the disease is conquered, a red circle is observed at some little distance from the mortified part, which, by degrees, suppurates, separating the diseased from the healthy portion. Arsenic acts in the same way. No part is destroyed, but, by the inflammation excited, the diseased mass is separated from the sound. In this action, it coincides with what we have observed of its general effects, which we found to be those of a stimulant and tonic; and the opinion is supported by the similar effects of a remedy, whose powers we found greatly to resemble those of arsenic; we mean mercury. In the *bay sore*, which is a true cancer, occurring on the coast of Honduras, we are informed, by Dr. Moseley, that an effectual cure is obtained by an application of corrosive sublimate. About a scruple is sufficient for a cancer, which a plaster of diachylon, about the size of a crown piece, would cover. Mr. Justamond, in some instances, joins the corrosive sublimate with arsenic. Opium, added to both applications, mitigates the pain without injuring the efficacy of the remedy. The argentum nitratum, with opium, is sometimes applied the day before the arsenic, to destroy the integuments, in which it supplies the place of the crowfoot in Plunket's receipt.

When ulceration has begun and is spreading; when the tumour is fixed to the ribs; the glands leading to the axilla swelled; art can no longer promise relief. To ease the pain and lessen the factor of the discharge, are all its pretensions, and these objects are often attained by opium, hemlock, the carrot poultice, oxygenated muriatic acid, goose grass, and fixed air. Opium and hemlock may be given for the relief of pain.

internally, and applied externally in poultices or washes: the others are applied externally only. The fixed air has been thrown against the sore from an elastic bottle, or a bladder armed with a proper pipe; or the part has been bathed by the acidulous water. Mr. Justamond, for a similar purpose, advises the powder of the calamus aromaticus, or of the flowers of zinc; to either of which as much crude sal ammoniac as the state of the ulcer will allow may be added. Even in this state, however, the ulcer sometimes suddenly heals; but, it is, as we have said, to carry its destructive influence to other parts; and this unexpected change has given credit to the numerous nostrums so industriously recommended.

Mr. Bell, in his *Treatise on Ulcers*, edit. 3. p. 299, &c. observes, that *cancers* are most frequently in the lips in men, and the breasts in women. The sooner, we have remarked, the operation is performed, the greater is the chance of the extirpation proving effectual. This, however, is contradicted positively by Mr. Pearson. "If," says he, "the removal of the morbid part were equally complete in two patients, one of whom had been afflicted seven months, and the other seven years, with a cancer, I should esteem the latter in less danger of a relapse than the former. For example, when the breast is affected by a cancer, distant parts of that gland may become the seat of the morbid alteration about the same period. These several diseased portions may not advance with equal celerity; but, while one part acquires a considerable bulk, the other altered parts may be scarcely objects of attention. Under such circumstances, the more obviously morbid parts may be removed; but, the disease being only in progression, no man can be certain, without removing the whole breast, that he has not left some diseased fibres. If, however, the disease shall continue without increasing during several years, one may in general conclude that its boundaries are more accurately defined." Conscious that such accidents may occur, Mr. Bell therefore advises, when the complaint is on the breast, although part of it only may be affected, the whole should be always taken off. But, although it be proper to extirpate every part that is really diseased, none of the sound external teguments should be ever unnecessarily destroyed, nor should more of them be taken away than is requisite. A little before the sore heals up, an issue should be established, so as to discharge freely before the cicatrix is formed. If scirrhus or cancerous disorders appear in several different parts, the removal of any or all of them would not probably be effectual. If *cancers* adhere to another adjacent part, they rarely can be extirpated with safety; a cancerous tumour may be attached to a circumjacent muscle or tendon, and may admit of an operation: however, much prudence is requisite in attempting a desperate case. See also Bell's *Surgery*, vol. ii. 434, where he directs how to amputate cancerous breasts. See AMPUTATIO.

When tumours of the axillary glands occur, their extirpation also is generally recommended. We have, however, suspected that this is unnecessary, for we have found them remain indolent for years after the operation has succeeded. Yet it is a prudent precaution.

CANCER ON THE FACE is generally seated on the lips, nose, or eye lids. When these ulcerate, they are al-

ways attended with a hardness, which extends in proportion as that which formed the first tumour is destroyed by erosion, and is always preceded by a change in the colour of the skin, which, before it indurates, turns red; and, in extirpating, all that is thus florid must be cut away, as well as the part that is manifestly cancerous. See Le Dran's *Observations*. When a cancer on the lip becomes ulcerous, it appears at first like a crack, and then gradually widens. In extirpating cancerous lips, the operation is best performed as for the cure of the hare lip. Mr. Sheldon observes, that cancer in the cheek, which no operation can cure, proceeds from a polypus.

CANCER IN THE INTESTINES. In this case the patient is continually afflicted with a highly acrid and obstinate discharge from the bowels resembling dysentery; which corrodes all the parts it touches, and is attended with frequent convulsions and fixed pains.

CANCER IN THE TESTICLE. The most powerful means may be tried; great advantage hath followed the internal and external use of hemlock, but castration is generally the *sad* but safest resource.

CANCER IN THE WOMB. This disease, we have said, happens generally about the time of the menses disappearing, but may occur at any other period of life. It is known by tensive lancinating pains in the pelvis and womb; indurations in the part, sensible to the touch, a preceding immoderate discharge of the whites, sometimes of the catamenia, or both. *Ætius* remarks, that "there is a violent pain in the groins, upper part of the belly and loins, whilst the parts originally affected can hardly bear to be touched: but, if the cancer is ulcerated, besides the pain and hardness about the neck of the womb, there are ulcers with tumid, sordid, and whitish lips, and from them a fetid sanies flows." The discharge from these ulcers is very various, being sometimes bloody, sanious, or accompanied with sloughs. If the indurations are not ulcerated, the discharge is sanious and acrid. In time the labia swell, and are œdematous; and if, as sometimes happens, the inguinal glands are obstructed, the œdema extends along the thigh.

In this unhappy case, besides the general methods, a close adherence to the extract. or semina cicutæ must be insisted on; beginning with a small dose, and increasing it gradually. This sometimes moderates the pains better than opium. Mr. Justamond, in this case, depends much on the bath and injections of hemlock. See CANCER.

Mr. Le Febvre recommends, in case of cancerous ulcers in the womb, that injections should be frequently thrown up of a decoction of carrots and hemlock, having four grains of opium, and as much arsenic, dissolved in every pint. When in the bone or bones of a limb a cancer takes place, the amputation of that limb will be necessary.

The peculiar advantages of Mr. Fearon's mode of excision of the breast, and his after treatment, merit attention.

The patient being seated conveniently with her head supported upon a pillow, by an assistant behind, and her arms held by one on each side, the surgeon makes a horizontal incision, in the direction of the ribs, a little below the nipple; the assistants then draw the teguments as far asunder as possible, and press their fingers

on the bleeding arteries, whilst the surgeon is dissecting the diseased mass from the skin above, and the pectoral muscle or parts below: after which, the wound being carefully examined, every small indurated part is to be removed.

The hæmorrhage by this time generally ceases; but if an artery still bleeds freely, it must be secured by means of the tenaculum and ligature, the ends of which are left a proper length out of the wound. The whole is then cleaned; and the parts and edges of the wound are laid in even and perfect contact, and retained so by two, three, or more sutures of the interrupted kind, according to the extent of the wound, and by the applications of slips of adhesive plaster, in the intermediate spaces, across the line of incision.

About the third or fourth day the serous discharge appears through the bandages, and the slips of plaster grow loose and require to be removed: the stitches in the teguments are then to be divided with a pair of scissors. The incision is afterwards dressed daily with small slips of lint, spread thin with a mild cerate made of the purest oil and wax. The ligatures by which the arteries are secured, are gently drawn every day after the first inflammation is abated, and taken away in due time for the secondary union, or what is termed adhesive inflammation, to take place. The cure is greatly accelerated by repeatedly supporting the edges with a few slips of adhesive plaster.

When the skin is ulcerated or diseased, a second incision is made in as straight a line as the inclusion of the diseased part will admit, down to the extremity of the first; and the edges are brought together in the same manner as in the first incision. The incision is to be made below the nipple, because the natural position of the part more readily assists the union, and the breast is less subject to deformity.

Thus the cure is generally completed in a fortnight or three weeks; nay, sometimes in as many days as weeks, where the suppurative process has been allowed to take place. A large, thick, soft compress made of linen, which has been in use, is to be applied after each mode of dressing; and a linen, or rather a flannel roller, about five inches broad, and six or eight yards long, bound gently tight over all. The arm on the affected side is to be supported in the bent position by a handkerchief tied round the neck. It has been a former custom to suffer the wound to remain long open, with a view to drain off the remaining virus; but this has been found tedious and useless.

We have omitted mentioning one remedy, which, if we recollect rightly, is recommended in the Memoirs of the Royal Society of Medicine at Paris; we mean lizards. This remedy was said to have been used in South America; and, though a particular species was mentioned, it was added that almost every other had a similar effect; and we find, in some authors, the *lacerta agilis* recommended for this purpose. The whole lizard tribe, dried and powdered, is recommended as sudorifics and alterants. The lizards, in cancers, were said to promote a considerable discharge of yellow, offensive sweat, which relieved the pain and diminished the tumour. We know of no species that is poisonous.

CA'NCER MUNDITO'RUM. *Chimney sweeper's Cancer.* See SCROTUM.

CA'NCER O'SSIS. See SPINA VENTOSA.

CA'NCHRY, or CA'NCHRYS. See CACHRYS.

CANCINPE'RICON. Hot HORSE DUNG. See ANHELATIO.

CANCRO'RUM LAPIDES, (from *cancer*, a crab). See OCULI CANCRO'RUM.

CA'NCRUM O'RIS, (from *cancer*, a spreading ulcer). CANCER OF THE MOUTH; called also *aphthæ serpentes*, *librisulcium*, *gangrena oris*, by Le Dran *cheilocæce*. It is a deep, foul, irregular, fetid ulcer, with ragged edges, which appears upon the inside of the lips and cheeks; and is attended with a copious flow of offensive saliva.

This disease is seldom seen in adults, but it most commonly attacks children. When the ulceration begins at the inner part of the lip, it exhibits a deep, narrow, sulcated appearance, and quickly spreads along the inside of the cheek, which becomes hard, and tumefied externally. The gums are very frequently affected, the teeth are generally loose and diseased; matter is often found in the sockets, and abscesses sometimes burst externally through the cheek, the lip, or a little below the maxilla inferior: and it is not uncommon to see an exfoliation of the alveolar processes, or even of the greater part of the lower jaw. Among the children of poor people, where this disease is often neglected or mismanaged, a gangrene will sometimes supervene.

In order to the cure, it will be proper to remove any diseased teeth or bones if possible; to prescribe a milk and vegetable diet, and to allow a prudent use of fermented liquors; to give the Peruvian bark, sarsaparilla, elm bark, and mineral acids.

External applications may be preparations of copper: a diluted mineral acid: burnt alum: decoction of bark, with borax, or tincture of myrrh. See APHTHE: also Pearson's Principles of Surgery, vol. i. p. 262.

CANDE'LA. A CANDLE, (from *candeo*, to shine). Exhalations from candles are salutary or hurtful, according to the materials of which they are formed. Old tallow often sends off bad fumes; wax, though white, creates the head ach, and often hurts weak lungs; hogs' fat is very offensive; beef tallow alone is not good; that of sheep affords the best.

CANDE'LA FUMA'LIS, or *candela pro suffitu odorata*; called so from *fumus*, smoke, from their odoriferous effluvia; called also *tæda*, *avis*, and *avicula Cypria*. These are made of odoriferous powders, mixed with one third or more of the charcoal of willows or lime tree, and reduced to a consistence with turpentine, labdanum, &c. Resinous substances alone may be mixed with balsamics; they give out a grateful odour, purify the air, and raise the spirits. They were formerly burnt in times of pestilence: they are also, from their form, called *bacilli*, and *massæ ad fornacem*, because they are usually applied to a hot grate or chimney to diffuse their smell without lighting them. See Cho-

mel's Dict. Œconomique: for *Candela, medicata*, see BOUGIE.

CANDE'LA REGIA, and CANDELARIA. See VERBASCUM.

CAN'DUM, a corruption of *canthum*; SUGAR CANDY. See SACCCHARUM.

CANE'LA, (from *canna, a reed*). A word used by the ancients for CINNAMON, or rather CASSIA.

CANE'LLA, (from the same). See CINNAMOMUM.

CANE'LLA A'LBa, (from the same; because these barks have a reed like appearance, from being rolled up in that form). Called also *canella cubana*; *Malabarica*; *winterana*; *Jamaicensis*; *tubis minoribus alba*; *cinnamomum album*; *Malabaricum*; *aromaticum lignum*; *aromaticus cortex*; *caminga*; *caryophylli suavis odoris*; *winterania canella*; *cortex winteranus'spurius*; *cassia lignea Jamaicensis*; *arbor Jucadice*; WILD CINNAMON TREE. *Winterana canella* Lin. Supplem. 247. *Canella alba* Murray Syst. Veg. 443, and Swartz. Lin. Trans. v. i. p. 96. *Canella alba* Lin. Sp. Pl. Wilde-now, vol. ii. p. 851. Nat. order, *oleraceæ*.

The bark of this tree is commonly, but falsely, called *cortex winteranus*. It is a large tree, whose bark consists of two parts, an outward and an inward; the outer is as thin as a milled shilling, of an ash grey colour, with whiter spots here and there, and several shallow furrows of a darker colour running variously through it; the taste is aromatic. The inner bark, which only is employed, is thicker than that of cinnamon, being as thick as a milled crown piece, smooth, of a whiter colour than the outward, inclining to yellow, and of a more biting and aromatic taste, resembling that of cloves, and not glutinous when chewed, but dry, and crumbling between the teeth. It is called the West India cinnamon tree. The bark is of different thickness, according to the age and size of the branch from which it is taken.

It grows in Jamaica, Antigua, and other of the Caribbee islands. The bark is the chief part in use, the poor natives employ it instead of all other spices; its virtues, though similar, are very weak. It is sold in England for the cortex winteranus, for its virtues are the same: it yields a heavy oil, which, when mixed with a little oil of cloves, is sold for it; and Dr. Brown adds, the adulteration is no prejudice to the credit of the oil of cloves. It is a pungent, bitterish aromatic, not very agreeable in taste. Water extracts only the bitter, but proof spirit both the bitter and aroma. It is used in dyspepsia, and to warm some of the less agreeable or narcotic bitters. See Miller's Bot. Off. and Dr. Brown's Natural History of Jamaica. Woodville's Med. Botan.

CANELLA JAVENSIS, MALABARICA. See FOLIUM, and CASSIA LIGNEA.

CANELLA SYLVESTRIS MALABARICA. See FOLIUM.

CANELLA CUURDO, ZEYLANICA. See CINNAMOMUM.

CANELLI'FERA MALABA'RICA, (from *canella*, and *fero, to bear*). See CASSIA LIGNEA.

CANICA, a spice used in the island of Cuba, probably the pimento; or from some of the species of myrrhs.

CANICÆ. Coarse meal was anciently thus called,

from *canis, a dog*, because it was food for dogs. Hence *panis canicaceus*, very coarse bread.

CANICIDA, (from *canis, a dog*, and *cædo, to kill*, so called because they are destroyed by eating it). See ACONITUM.

CANICI'DIUM, (from *canis, a dog*, and *cædo, to cut*). A dissection of living dogs.

CANICULA'RIS, (from *canicula, the dog star*). DOG DAYS. This is the time when the canicula, or dog star, rises and sets with the sun. Some centuries ago they began about the middle of July, or somewhat later, and ended about the latter end of August or beginning of September; but the heliacal rising and setting of this star are now at a different period: these days, however, still retain in our almanac this appellation, and the idea of the dog days is connected with extreme heat. In some countries they continue to maintain the opinion, that bleeding and other evacuations are not efficacious in this season, or rather in very hot weather, because of the unusual languor of the patient; and probably with reason.

CANI'NA APPETE'NTIA, (from *canis, a dog*, and *aphetens, hungering*). *Fâmes*. See BOULIMUS.

CANI'NA BRA'SSICA. See MERCURIALIS SYLVESTRIS.

CANI'NA L'INGUA. See CYNOGLOSSUM.

CANI'NA MA'LUS. See MANDRAGORA.

CANI'NA RA'BIES. See HYDROPHOBIA.

CANI'NI DE'NTES, called also *dentes cynodontes*. The teeth betwixt the incisores and the grinders, of which there is one in each side, both in the upper and lower jaw. See DENS.

Mr. John Hunter, in his Natural History of the Human Teeth, names these *cuspidati*, because, though made somewhat like the incisores, they have the two sides of the edge sloped off to a point, and this point is very sharp. Their fangs are longer than those of the incisores, and, therefore, from the fangs of those in the upper jaw being supposed to extend the greatest part of the way to the eye, they have been called the EYE TEETH. Their use seems to be to hold what is caught or taken. In Varro and Pliny they are called *columellares*.

CANI'NI MINORES. The incisorii laterales musculi sometimes send a few fibres to the musculi canini, to which Winslow gives the above name.

CANI'NI MUSCULI. Winslow says that each of the two musc. *canini* are fixed above the socket of the dens *caninus*, and terminate in the arch of the orbicularis labiorum.

CANI'NUS SE'NTIS, (from *canis, a dog*, and *sentis, a thorn*, from its being prickly like a thorn). See CYNOSBATUS.

CANI'RAM. (Indian.) Called also *malus Malabarica*. It is a large tree, bearing a smooth gold coloured apple, whose pulp is white and mucilaginous: this fruit is remarkably bitter, and so are its seeds, and indeed the whole tree. The root is cathartic, the bark restraining. Raii Hist. The root of the *strychnos nux vomica* Lin. Sp. Pl. 271.

CANIRU'BUS, (from *canis, a dog*, and *rubus, a bramble*). See CYNOSBATUS.

CA'NIS, also *cy'on*. A DOG. Gloves made of dogs' skins are worn in summer to keep the skin smooth and cool. The external surface of these skins

is smooth, and, as is common with polished bodies, reflect the heat. The white dung of this animal was formerly in esteem, but is not now used. See ALBUM GRÆCUM.

CA'NIS. See PE'NIS.

CA'NIS INTERFECTOR. See CEVADILLA.

CA'NIS PONTICUS. See CASTOR.

CANIT'IES, (from *canus*, grey headed). Grey-ness of the hairs, or grey headed.

CANNA, (from the Hebrew *kanna*, a reed, or *hol-low cane*). It is applied to many substances, from some similarity in their appearances; viz. *cánna doméstica májor cruris*, and *cánna májor*. See TIBIA.

CANNA FI'STULA. See CASSIA FISTULARIS.

CANNA INDICA. See SAGITTARIA ALEXIPHARMI-CA.

CANNA MI'NOR CRU'RIS. See FIBULA.

CANNABI'NA, (from *canna*, a reed, so named from its reed like appearance). See ACMELLA.

CANNABI'NA AQUA'TICA. See BIDENS.

CANNABI'NUM. See EUPATORIUM.

CA'NNABIS. HEMP, or SEED BEARING HEMP; *cannabis sativa* Lin. Sp. Pl. 1452. It is a tall annual herb with digitated leaves, cultivated in the fields on account of the mechanic uses of its tough rind. Some of the plants, called male, produce flowers composed of yellowish stamina set in five leaved cups; others, called female, produce seeds moderately large, covered with a shining dark grey coloured shell, under which is lodged a white kernel.

This plant hath a rank smell of the narcotic kind, which is supposed to injure the health; the effluvia of the fresh herb are said to weaken the eyes and affect the head; and the water in which the herb hath been steeped, for facilitating the separation of the tough rind, is thought to be a violent and sudden poison. Both in smell and taste it is highly deleterious.

The leaves of an oriental *hemp*, called *bang* or *bangué*, and by the Egyptians *assis*, are said to be used in the eastern countries as a narcotic and aphrodisiac. See BANGUE.

The faint smell of the seeds goes off in keeping; their taste is unctuous and sweetish, accompanied with a slight warmth. On expression, they yield much insipid oil, which unites with water by trituration into an emulsion. Decoctions of them in milk are commended in coughs, heat of urine, and in all cases where the mucus has been abraded: their use, in general, depends on their emollient and demulcent qualities. Miller's Bot. Off.

CA'NNABIS I'NDICA PEREGRI'NA. See BANGUE and CANABIS.

CANNA'CORUS RADI'CE CROCE'A, (from *κωνν*, a reed, and *αροπος*, a flag). See CURCUMA.

CA'NNULA, (a dim. of *canna*, a reed). A name for several instruments in surgery: they are tubes of different shapes and sizes; introduced into openings for the conveyance of a fluid from the part.

CANO'NIAI, (from *κανων*, a rule of measure). Hippocrates, in his book De Aëre, &c. gives this appellation to persons who have not prominent bellies. He would intimate that they are formed as it were by a straight rule: hence the term. This word, *canoniai*, is corruptly used for *canonii*.

CANOPI'TE. The name of a collyrium mentioned by Celsus.

CANO'PUM. In P. Ægineta it is both the flower and the bark of the elder tree.

CANSCHENA-POU. See MANDARU.

CANSJA'VA. See BANGUE.

CANTA'BRICA, also called *convolvulus minimus spica foliis; convolv. linaria folio; convolvulus cantabrica* Lin. Sp. Pl. 225. Pliny says it is an herb that was discovered, in the time of Augustus, in the country of the Cantabri in Spain. It grows wild in the field, flowers in June, and is commended against worms. Like all the convolvuli it is actively cathartic. See CONVOLVULUS CANTAB.

CANTA'BRUM, (from the Hebrew word *kanta*). See FURFUR.

CA'NTACON. GARDEN SAFFRON.

CA'NTARA. See NUX VOMICA SERAPIONIS.

CA'NTHARI FIGULI'NI. Cucurbits made of potter's ware. See CUCURBITA.

CANTHA'RIDES, (from *καραβος*, a beetle, to whose tribe it belongs). FRENCH FLIES, *Musca Hispanica*, SPANISH FLIES, *cantharis major Meloe vesicatorius, alatus viridissimus nitens, antennis nigris*. Lin. Another kind is called BUPRESTIS. In the system of La Treille the cantharis is separated from the genus *meloe*; and the insects with filiform horns, or antennæ, half as long as the body, composed of eleven joints, are united into one family, styled the *cantharidæ*. The genus *cantharus* contains twenty-two or twenty-three species. After the blistering cantharis, the most known are the *c. dubia* and *Syria*. Those in general use were formerly brought only from Spain, whence they were called *Spanish flies*; but they are met with in France, Italy, Germany, and other countries. Neumann says that they are found chiefly in the spring season, and on poplar and ash trees; but they occur also on nut, rose, and other trees, whose leaves they devour; and when this food fails, they attack corn and grass, in which they make the most destructive ravages.

They are an insect of the beetle kind, known by their shining gold green colour, which is also of a bluish cast. They have a strong and sickly smell; when tasted they make no impression on the tongue at first, but presently an acrimony and pitchy flavour are perceived.

The largest and best are brought from Italy; they should be chosen fresh coloured, entire, and free from dust. Neumann says, that after long keeping they fall into a grey brown powder, and in this state are unfit for use, their intrinsic qualities perishing with their external form. Experience, however, contradicts this idea.

Baglivi supposed that cantharides were introduced into medicine by the Arabian physicians, though they were evidently known to Hippocrates; but the animal appears to have been different. From the description of Dioscorides, the ancient physicians apparently employed the *mylabrum cichorci*. The Chinese, at this moment, use the same insect for the purpose of blistering; and the *mylabrum* is very common in the east, where Dioscorides lived. The attention paid to the cantharis has occasioned the other kinds to be neglected. Many of the species are perhaps equally active, and others may, from a less degree of acrimony,

be adapted for internal use. Of the other genera, which may be equally useful, the meloe, the mylabrum, the scarabæus, tenebrio, cicindela, and coccinella, may be suggested as subjects of trial. Many of the caterpillars contain on their bodies an acrid dust, which, dispersed in the air, irritates the skin and the eyes.

Cantharides appear in troops or swarms, and are discovered by their fetid smell. They are usually shook from the tree into a cloth, and exposed in a sieve to the vapour of vinegar; or they are collected in a fine cloth, and repeatedly immersed in vinegar. Another method is, to spread cloths under the trees and boil vinegar around: they are then placed for a little time in jars before they are exposed to the air to dry. They are dried in the sun, though more frequently in an airy place, from whence the sun is excluded, or covered with paper. In turning them, the workmen wear gloves, as they would otherwise experience troublesome heats of urine, ophthalmies, and pains in the neck. Cantharides, when well dried, are so light that fifty scarcely weigh a drachm.

Every animal has its enemy, and even this acrid insect is preyed on by another. Cantharides do not lose their virtue by keeping, or by having been for a long time powdered. When kept, some insect reduces them to dust, which is, however, equally efficacious with the cantharis recently powdered, for the animal seems to devour only what we shall afterwards distinguish as the parenchyma.

The chemical history of cantharides has not been sufficiently examined; and what is known has not yet been published in any English work. We have only received tolerably accurate accounts from MM. Thouvenel and Beaupoil; but, as the last, though not perfectly satisfactory, are more so than the former, we shall chiefly rest on his experiments from the 48th volume of the *Annales de Chimie*; premising, however, very shortly the conclusions of Thouvenel, which we have only seen in the first volume of the *History and Memoirs of the Royal Society of Medicine at Paris*, p. 333. These insects, it is observed by M. Thouvenel, besides the parenchyma, which forms one-half of their weight, affords, 1st, An extractive matter of a green yellow colour, resembling that of ants (see *FORMICA*); 2dly, A yellow insipid oil, resembling the spirituous tincture of these animals; 3dly, A green oily concrete matter examined with much care, not unlike wax, but of a pungent taste, and resembling the insects in smell; and affording, by analysis, the same component parts. In this, M. Thouvenel thinks the chief virtue of cantharides resides; and he seems to be convinced that the extractive matter envelopes the oily, so as to prevent the latter from being wholly soluble in vinous spirits. He was thence led to employ proof spirit; and this menstruum dissolves all the green active matter with so little of the extractive, as not to impede its virtues. This tincture M. Thouvenel has employed in his medical experiments; and, when applied externally, he found it a tonic, a resolvent, useful in rheumatisms, sciatica, wandering gout, and pains in the side.

M. Beaupoil has engaged in the subject at a greater extent. He has described the specific characters of the cantharides, the means employed to collect them, and the preparation they undergo previous to their intro-

duction as objects of commerce. In the second part he has slightly glanced at their use, from the time of Hippocrates to the present. In these parts there is nothing new. The third part relates to their analysis; and the fourth to the effects of the cantharides entire, or their component parts, on himself and different animals.

In his chemical examination he found the same ingredients as M. Thouvenel; but he examined them separately, and in this the merits of his labour consist.

The extractive matter reddened the tincture of Tournesol, but appeared of an animal nature, quickly putrefying, with a strong smell of ammonia. In distillation the black portion, not soluble in alcohol, swelled, gave out an acid fluid, a thick oil, and carbonate of ammonia, leaving a dry, shining, friable coal. The portion which alcohol dissolved, preserved, when inspissated, the smell and taste of the extract; it dissolved perfectly in water combined with potash, without separating any ammonia. In distillation it afforded similar ingredients with the insoluble portion, but in less quantity. On examination of the acid, it approached in its properties the phosphoric, though it differed from it, and seemed of a peculiar nature. It was certainly not derived from the vinegar, with which the animals are generally killed.

The green matter is not changed by the air; is insoluble in cold water, and melts in hot water, swimming on the surface like oil. Alcohol and ether dissolve it, and water separates it from these menstrua. The oxygenated muriatic acid gradually decomposes it. The substance loses its smell and colour; becomes thick and glutinous; preserving, notwithstanding repeated affusions of water, the smell of the oxygenated acid. Weak nitrous acid gives it a brown red colour, a rancid, pungent smell; adding greatly to its consistence. Caustic soda unites with it, without separating any ammonia; and the compound is disunited by acids. In a high degree of heat it forms an oily, slightly transparent fluid, which, on cooling, soon becomes solid. When urged by heat it separates into a yellow oil like that from distilled wax, and an acid water without an atom of ammonia. The parenchyma, left after the different macerations, infusions, and decoctions, when examined by caustic potash, gives a very sensible smell of ammonia. When this disappeared, the addition of muriatic acid formed a precipitate wholly of an animal nature. In the cinders, when burnt, were found carbonate of lime, calcareous phosphat, sulphat, and muriat of lime, with oxide of iron. An ounce of cantharides, in this way, afforded one drachm two grains of the black insoluble matter; as much of the yellow; about six grains more of the green matter; four drachms thirty-six grains of parenchyma; an indeterminate quantity of acid; twelve grains of calcareous phosphat; of carbonate of lime and oxide of iron two grains each, with four grains of sulphat and muriat of lime.

M. Beaupoil found from his experiments, that cantharides, given without any preparation, chiefly affected the œsophagus, the stomach, and the small intestines. Animals not killed by them suffered great pain and violent inclination to vomit; 2dly, The watery extract produced the same effects in less doses, and showed a more decided action on the urinary organs; 3dly, The black insoluble matter is less active than the extract;

and, though it produced the former inconveniences, was seldom fatal; 4thly, The green matter seemed in no respect deleterious, and the yellow was scarcely more active; 5thly, The extract, the green and the yellow matter, applied to the skin, produced blisters in nearly the same time; but the yellow matter seems not to act till it is divided by wax in the form of a cerate. The author repeated these experiments on himself, and found the vesicatory properties of the cantharides resided essentially in the extractive and green part of the insect, but that the extractive exclusively acted on the urinary and genital organs.

M. Deyeux, to whom we owe this abstract in the *Annals*, very properly observes, that it is by no means complete. He particularly remarks it as singular, that the green matter should act as a blister, while it produces no effects on the animal economy. The author has promised to examine the subject again, and we may find some room for his further elucidations in a subsequent article.

It has been thought that they peculiarly affect the kidneys and urinary passages, proving diuretic; though whether they affect the former may be doubted, if we can believe the evidence of Dr. C. Smith and Dr. Cullen, to which our own experience may be added. Werlhof, however, gives a remarkable instance of the diuretic powers of cantharides; and tells us he had frequently experienced them in dropsy and other diseases. He gave a grain of the powder in a dose, repeating it every four hours; and it was only after the third dose, in a case of suppression of urine of many days standing, that it began to yield: still Werlhof discontinued the use of cantharides in dropsy and other diseases; and, as when the strength decays suppression spontaneously yields, we suspect that weakness rather than the remedy occasioned the flow. A blister to the loins has increased a flow of urine, but this remedy seems to act on another principle. Externally they are caustic, and are used to raise blisters, for which end Aretæus first rubbed them on the head.

In nephritic cases with inflammation, in calculus of the kidneys and bladder, occasionally in pregnancy, their use is not to be admitted.

However used, they are apt to produce a strangury and inflammation of the urinary passages. When blisters are applied, the assistance of nitre, oily drinks, mucilaginous soap, and camphor, in large doses, are required. Pressing a piece of gauze into the plaster will often prevent strangury, or removing it when the blister is first raised. Washing the blistered part, when dressed, with warm milk, greatly relieves these symptoms. When imprudently taken into the stomach, they cause great heat, inflammation, bloody urine, a priapism, thirst, and a cadaverous breath. Nitre, camphor, milk, oil, mucilage of gum arabic, and copious diluting drinks, are the antidotes.

A dose of the powder may be from half a grain to six grains; and of the tincture from five to fifty drops, twice a day. By gradually increasing a small dose, a much larger quantity may be taken.

The powdered flies, the spirituous extract, or the watery one, applied to the skin, blister it equally; but the best preparation for internal use is the tincture. Mead recommends them in cutaneous complaints; and

in the moist tettery eruptions of old people they have, we think, been serviceable. In incontinence of urine, cantharides are useful medicines; and in blenorragia and leucorrhœa, they are sometimes employed, it is said, with effect. When not used to raise blisters, they are beneficial as topical stimulants; and the tincture is occasionally employed for this purpose rubbed on paralytic limbs.

The London college directs the following preparation of the *TINCTURA CANTHARIDIS*.—Take of cantharides bruised, two drachms; of cochineal, half a drachm; of proof spirit of wine, a pint and a half; digest for eight days, and strain.

Balsams are sometimes added; and the tincture, with this addition, is thought more useful when the kidneys, womb, or bladder, are ulcerated, or the urethra is corroded; but additions are best joined extemporaneously, or interposed by themselves at proper intervals. The diuretic power of the flies is much improved by the addition of *sps. ætheris nitrosi*.

The *UNGUENTUM CANTHARIDIS*, formerly *unguentum ad vesicatoria*, is made by boiling two ounces of cantharides in eight ounces of water to four. To the strained liquor add eight ounces of the ointment of yellow resin. Evaporate this mixture in a water bath, saturated with sea salt, to the thickness of an ointment.

Its use is to dress blisters that must be kept constantly open.

*EMPLASTRUM VESICATORIUM*. Now *emплаstrum cantharidis*.—Take of Spanish flies, one pound in powder; plaster of wax, two pounds; prepared hog's lard, half a pound: having melted the plaster and lard, a little before they coagulate, sprinkle in the flies. Most skins are softened by bathing them with warm vinegar; and if a blistering plaster is applied immediately after, in some instances it produces a speedier effect. Complaints have been often made of the failure of blisters, which have arisen from neglect or ignorance: the apothecary, therefore, should be careful to have the flies good, but not in too fine a powder; and the plaster must be neither made in too great quantity at once, nor spread with too hot a spatula.

*CERATUM CANTHARIDIS*, is made by mixing one drachm of Spanish flies with six drachms of cerate of spermaceti softened by heat.

In cases where the common plasters are thought to be too active, Dr. Percival commends the following composition and manner of application. It is chiefly used to keep up the discharge from blisters.

*EMPL. VESICATOR. MITIUS*.—R. empl. vesicat. Ph. Lond. p. i. vel ij. empl. stomach. p. i. vel ij. camphor in *spt. vin. solut.* ʒ i. vel ij. m.

If a plaster of this composition be moderately warmed before the fire, then covered with a fine soft piece of gauze, it will occasion much less irritation than the usual one, produce no strangury, or but in a slight degree, and when to be removed will separate from the skin with great facility. Nor will this covering prevent its vesicating effects. Blisters may be thus applied when the skin is disposed to erysipelatos inflammation from its great sensibility, or when the evacuating power is wanted without the stimulus. See *BLISTERS*.

See Lewis's *Mat. Med.* Percival's *Essays Med. and*

Exp. edit. 2. p. 183, 248. Mémoires de la Société Royale de Médecine, v. 1. Annales de Chimie, v. 48.

CA'NTHI, CA'NTHUS. *Κανθός*, a primitive in the Greek. AN ANGLE OF THE EYE. *Anguli oculi*, also *epicanthides*. The cavities at the extremities of the eyelids, called the corners of the eyes; the greater canthus is next to the nose; the lesser canthus lies towards the temples.

CANTIA'NUS PU'LVIS. The Countess of Kent's powder. It is made with the rad. contrayervæ; coralium album crystal. terra Lemnia cerussa antimonii; mosch. ambergrise and saffron.

If cochineal be added, it is called *pulv. cant. rub.*; if calcined toads, *pulv. cant. niger*.

CA'NTION. A term for saccharum, sugar; but in conjunction with it, for sugar candy. See SACCHARUM.

CA'NTIUM, or CA'NTUM. A word used by the Greeks to signify angular, and applied to crystallized sugars, particular sugars in more regular crystals, candy.

CANTUARIE'NSES A'QUA. CANTERBURY WATERS. At Canterbury there are five wells not far from each other; they are strongly impregnated with iron, sulphur, and carbonic acid gas. Their taste is somewhat hard and austere; their smell is sulphureous. They are said to succeed in disorders of the stomach, in gouty complaints, the jaundice, diseases of the skin, and chlorosis.

CA'OVA. See COFFEA.

CAOUTCHOUC. (French). INDIAN RUBBER, OR ELASTIC GUM. Called also *Cayenne resin*, and *cautchuc*. It is prepared from the juice of a tree in Cayenne or other parts of South America. The Mexicans call it *olin*, or *olli*; the Spaniards of that kingdom, *ulé*; Aublet, *hevea Guianensis*; Jacquin, *echites corymbosa*; and Linnæus, in his *Supplementum Plantarum*, *iatropha elastica*. The hevea is the proper genus; though it is procured also from the urceola, described in the Asiatic Researches. v. 5. the artocarpus, the Indian, and probably our own, fig tree. The hevea is a monoicous plant of the family of the tithymaloïdes, nearly allied to the croton. The Indians obtain the juice of this tree by incisions made through the bark in its lower part, from whence it oozes out, under the form of vegetable milk, and is received in a vessel placed under the incisions. The milk, on exposure, gradually inspissates into a soft, reddish, elastic resin, and is commonly brought to Europe in the form of pear shaped bottles. It is soluble in rectified oil of turpentine, oil of wax, and of lavender, but more perfectly in ether. M. Bernard, in the Journal de Physique for 1781, has given many experiments on this substance, and has shown it to consist of a fat oil, insoluble in water or ardent spirit, but soluble in any oily fluid. The volatile alkali which it contains, is apparently furnished by the smoke in which the bottles are dried. The distinguishing properties of the substance are, its solidity, flexibility, and elasticity, and its quality of resisting the action of aqueous, spirituous, saline, oily, and other common solvents: from these properties it becomes extremely fit for *bougies*, *catheters*, *syringes*, and *pessaries*; to which purposes it is only medically applied.

CAPELI'NA, (from *capeline*, a woman's hat, or *bandage*; French). Or *capitalis reflexa*, CAPELINE DE LA TÊTE, *deligatio*, species 8.

A REFLEX BANDAGE. It is a double headed roller, about twenty-four feet long, and the breadth of four inches, sometimes narrower; the middle is fixed to the occiput, and, after two or three circular rounds, the rollers intersect each other upon the forehead and occiput; then one roller being reflected over the vertex or sagittal suture to the forehead, the other is continued in a circular tract; they cross each other upon the forehead, after which crossing the first head is carried back obliquely towards the occiput, and reflected by the side of the other; the last is continued in a circular direction, but the first is brought again over the sagittal suture, backward and forward, and so continued till the whole head is covered. It must be applied smooth and even upon the part which it surrounds, or on which it reflects. It is used in the hydrocephalus, but is not of any advantage.

CA'PER, and CA'PRA, (from *carpo*, to crop; because they are apt to crop the fruit and twigs from every plant and tree which they can come at). The HE and SHE GOAT; or *capra domestica*.

Dr. Cullen, in his class of *nutrentia*, reckons the milk of animals, amongst which he enumerates that of goats, and sets them down in proportion to their solid contents: thus, *women's*, *ass's*, *mare's*, *cow's*, *sheep's*, and *goat's*; and says, that the first three agree very much in their qualities, having little solid contents; and, when evaporated to dryness, having those very soluble, containing much saccharine matter; of very ready ascendency; and, when coagulated, their coagulum tender, and easily broken down. The last three are different, but the gradation is more obvious. Cow's milk comes nearest to the former milks: goat's milk is less fluid, less sweet, less flatulent; has the largest proportion of insoluble parts after coagulation, and indeed the largest proportion of the coagulable part. Its oily and coagulable parts do not spontaneously separate: they never rise in cream, or allow butter to be readily extracted. Hence the virtues of these milks are obvious, being *more nourishing*, though at the same time *less easily soluble in weak stomachs* than the first three, *less acescent than these*, and *so more rarely laxative*, and *peculiarly fitted for the diet of convalescents without fever*. The first three are *less nourishing*, *more soluble*, *more laxative*, *more acescent*, and *adapted to convalescents with fever*. Mat. Med. p. 112. Lond. 1772. See also LAC.

Goat's whey is *aperient*, *attenuating*, and *laxative*; it is generally preferred.

CA'PHURA BA'ROS INDO'RUM. See CAMPHORA.

CA'PHURÆ OL. An aromatic essential oil distilled from the root of the cinnamon tree.

CAPICATI'NGA. (Indian.) Species of acorns which grow in the West Indies, larger and more useful than those of Europe, with the same qualities in a greater degree. See CALAMUS AROMATICUS ASIATICUS.

CAPILA'CTEUM, (from *capillus*, a hair, and *lactum*, milky). See APHROGALA.

CAPILLA'CEUS, (from *capillus*, a hair,) resembling hairs or threads.

**CAPILLAME'NTA.** *Capillaments* are those slender filaments that spring up within the leaves of a flower, and are more usually called the stamina; whence a capillaceous flower is also a staminate one. Again, by *capillaments* are meant those slender parts which resemble hairs, and are produced from vegetables; as, for instance, from seeds or roots.

**CAPILLAME'NTUM.** The hairy or villous integuments belonging to animals. Called also *capilli-tium*, when applied to the hairy scalp in the human subject.

**CAPILIA'RES VERMI'CULI.** See CRINONES, and DRACUNCULI.

**CAPILLA'RIA VA'SA,** (from *capillus*, a hair).

**CAPILLARY VESSELS.** The smallest vessels in our bodies are so called, because they appear as small as hairs.

**CAPILLARIS.** Any thing that resembles hairs, applied to LEAVES that are longer than the setaceous, or bristle shaped leaf; to GLANDS resembling hairs; to FILAMENTS; to the STYLE; and to the PAPPUS or DOWN affixed to some seed. Capillary plants are those which have leaves of this description; and they are all supposed pectoral or demulcent. See ADIANTHUM.

**CAPILLATIO,** (from *capillus*, a hair). A capillary fracture of the cranium. See TRICHISMOS.

**CAPILLI'TIUM.** See CAPILLAMENTUM, and TRICHIASIS.

**CAPILLORUM DEFLU'VIUM,** (from *capillus*, and *defluo*, to fall off). See ALOPECIA.

**CAPILLUS,** (quasi *capitis pilus*, the hair of the head,) also *crinis*. The HAIR. *Capillus*, though strictly the hair of the head, is used also for hair in general. The hairs are hollow, and furnished with vessels; are knotted at certain distances, like some sorts of grass, and send out branches at their joints. The disorder called *plica polonica* proves them to be hollow. The branching of the hair is visible at the extremities with a microscope, and the hair is apt to split if worn long and kept dry. Each of these hairs has a bulbous root of an oval shape, which is lodged in the skin. It has been supposed, that as long as any moisture remains about the roots of the hair it continues to grow, though the body be dead and mouldering to dust; but this is a popular superstition, wholly without foundation.

Dr. Cheyne observes, that the strength of the hair is proportional to that of the constitution.

For its principal disorders, see ALOPECIA.

**CAPILLUS VE'NERIS CANADE'NSIS.** See ADIANTHUM CANADENSE.

**CAPILLUS VE'NERIS.** See ADIANTHUM VERUM.

**CAPIPLE'NIUM,** (from *caput*, the head, and *plenus*, full). See CATARRHUS. It is a barbarous word, but Baglivi uses it to signify that continual heaviness or disorder in the head which the Greeks call *carebaria*.

**CAPISTRA'TIO,** (from *capistrum*, a bridle). See PHIMOSIS.

**CAPISTRUM.** The name of some chirurgical bandages about the head, resembling a bridle, or rather a horse's head stall. See also TRISMUS.

**CAPISTRUM A'URI.** The soldering of gold. It is a name given to borax, because of its use in soldering this metal. See BORAX.

**CAPISTRY.** See FASCIA, N° 6.

**CAPITA'LIA,** (from *caput*, head). See CEPHALICA.

**CAPITA'NIS REFLE'XA.** See CAPELINA.

**CAPITA'TE PLA'NTÆ,** are plants whose seeds, with their down, being included within a squamous calyx, are conglobated into a roundish figure resembling a head. Hence are called *cephaloïdes*, or *cephalôtos*.

**CAPITE'LLUM,** (from *caput*, head). The head or seed vessels, frequently applied to mosses, &c. as in capitulum. Some suppose it to signify soapy water; others a lixivium.

**CAPITILU'VIUM,** (from *caput*, the head, and *lavo*, to wash). A bath or lotion for the head.

**CA'PITIS OBLI'QUUS INFERIOR** and *májor*. See OBLIQUUS INFERIOR.

**CA'PITIS PAR TERTIUM FALLOPII.** See COMPLEXUS MINOR.

**CA'PITIS POSTICUS.** See RECTUS MAJOR.

**CA'PITIS RECTUS.** See RECTUS MINOR.

**CA'PITIS VENA.** See CEPHALICA VENA.

**CAPIT'TULUM,** (a dim. of *caput*, the head). In botany, a species of inflorescence, in which several flowers form a kind of ball. In chemistry it is an alembic. (See ALEMBICUS.) In anatomy it is a smaller process or protuberance of a bone received by another bone.

**CAPIVI BA'LSAMUM.** (Indian.) BALSAM CAPIVI, called also *copaiba*, *capivus*, *album balsamum*. The tree which affords it is called *arbor balsamifera Brasiliensis*, *copaiba Brasiliensibus*, and *baccifera arbor Brasiliensis*, *fructu monophreno folio sesquipedali*. The tree grows spontaneously in the woods of Brasil, St. Vincent, and other of the British American islands. Deep incisions are made into the trunks of this tree during the hotter summer months; and one tree sometimes is met with that affords five or six gallons of balsam, but the same tree never yields it twice.

This balsam is at first limpid and colourless, and smells like calambour wood; as brought into Europe it is generally yellowish, and somewhat thicker than olive oil; by long keeping it becomes still thicker, but does not dry. In all states of its consistency, it continues clear and transparent. To the smell it is grateful, to the taste bitterish and biting; not intensely so, but durable.

To prove its genuineness, drop it on paper; if it spreads not, as oil, nor penetrates, it is good; on the contrary, if it spreads or sinks through, it is adulterated. It is also esteemed genuine when a drop, falling from the point of a needle into cold water, sinks to the bottom, or is suspended in the middle; but if it is suspended at the top, or spreads, it is spurious. If genuine, it is said that it does not give the violet smell to the urine of those who take it.

Distilled with water it yields half its weight, or nearly so, of essential oil; the remaining resin is tenacious and inodorous. If it is distilled in a retort, without any addition, by a fire gradually raised, it sends over first a light yellow oil, which smells strongly of the juice; then a dark coloured oil, and after it a fine blue oil, both which are pungent to the taste, having also an empyreumatic flavour, but not an ungrateful one. For its other properties and its use, see BALSAMUM COPAIBÆ.

CAPIVUS ALBUS. See CAPIVI BALSAMUM.

CAPNELAION, CAPNELÆUM. In Galen's works it is said to be a resin that flows spontaneously from some tree in Lacedæmon. In Cilicia it is called *capnelaion*, from *καπνος*, *smoke*, and *ελαιον*, *oil*, *smoky oil*; so called from its smoky exhalations when exposed to heat; but in Lacedæmon, and in some other places, it is called *πρωτόπυρρον*, *the first product*. Fæsius says it seems to be called *capnelaion*, because of the smoke it gives when placed near the fire.

CAPNI'STON, (from *καπνος*, *smoke*). A name of an oil prepared of several kinds of spices and oil, by kindling the spices, and thus impregnating the oil.

CAPNI'TIS, (from *καπνος*, *smoke*; so called from its smoky colour). See TUTIA.

CAPNOS. (Greek). SMOKE; so called, because if its juice is applied to the eyes, it produces the same effect as smoke. See FUMARIA.

CAPO, CAPUS. A name of the American TOAD. See BUFO. Also a CAPON, quia *testiculi ejus sunt capti*. The design of castrating a cock is to render him a fit leader for the other poultry, more fleshy, and more easily fattened.

CA'PO MOLAGO. See PIPER INDICUM.

CAPOLIN MEXICANO'RUM HERNANDEZ. (Indian). SWEET INDIAN CHERRIES, called also *cerasus dulcis Indica*. The bark is restringent. There are three species, the *xitoma capolin*, the *helocapolin*, and the *tolacapolin*. Raii Hist. We cannot discover this plant in any system.

CAPOTES. See COVALAM.

CAPPARIS, (from the Arabic term *cabar*). *Capparis spinosa* Lin. Sp. Pl. 720. The CAPER BUSH. It is a low prickly bush, grows wild in Italy, Spain, and the southern parts of France. Those of Provence are the best; those of Tunis, where they also grow, are very inferior. The plant, however, is originally an Asiatic one. The bark of the root is bitterish and acrid to the taste, and is ranked among aperients and diuretics. The green buds of the flowers are pickled in vinegar and salt, and are used at the table to assist the appetite. In Holland and Germany they substitute the buds of the flowers of the *cytisogenista scoparia vulgaris flore luteo* for the *capers*, and pickle them in the same manner. The plant grows in the crevices of the rocks and of old walls. The buds are numerous, and daily gathered, as they soon grow too large. Those which escape, and when the fruit becomes the size of a gerkin, are preserved in sugar. Capers are separated according to their different sizes by sieves, with suitable apertures: the small and green ones are preferred, which has led to a suspicion that an artificial colour is sometimes given. See CONDIMENTS.

CAPPARIS FABAGO, CAPPARIS PORTULACA, C. B. See FABAGO.

CAPRA ALPINA. The CHAMOIS, called also *ruficapra* and *dorcas*, the ROCK GOAT. It is met with on the Alps belonging to Switzerland, and in Germany. It is a species of wild goat, in shape and size resembling the tame one, with short horns, the ends of which are hooked. The balls found in their stomachs are called *ægagrophila* and *bezoar Germanicum*, formed of hairs which they lick. Such are found also in the stomachs of cows, hogs, and stags with us: when taken

from ruminating animals, they are called *bulithum*, or *cow's bezoar*; from stags, *elaphophila*.

CA'PRA DOMESTICA. See CAPER.

CA'PRA MOSCHI. See MOSCHUS.

CA'PRA STREPSICEROS, (from *στρεψω*, *to turn*; so named from his crooked horn). See ANTILOPUS.

CAPREOLA'RIS, CAPREOLA'RIA, (from *caprea*, *a tendril of a vine*). See SPERMATICA CORDA.

CAPREO'LUS, A TENDRIL; in anatomy, is the HELIX of the ear (see AURICULA); and in zoology the ROE BUCK, which is also called *caprea Plinii*, and *dorcas*. It is found in Scotland and other parts.

CAPRICE'RVA OCCIDENTA'LIS, (from *caprer*, *a goat*, and *cervus*, *a stag*). A West Indian deer participating both of the nature of the deer and stag, affording the West Indian bezoar.

CAPRICE'RVA ORIENTA'LIS. The deer in which the East Indian bezoar is found.

CAPRICO'RNUS. See PLUMBUM.

CAPRI'FICUS, (from *caprer*, *a goat*, and *ficus*, *a fig*; because they are the chief food of goats). See FICUS SATIVA.

CAPRIFO'LIUM, (from *caprea*, *a tendril*, and *folium*, *a leaf*; so called from its tendrils). HONEY SUCKLE or WOODBINE. Also called *matrisylva*, *periclymenum*, *chamæcerasus*. It is the *Lonicera periclymenum* Lin. Sp. Pl. 247; and is a climbing shrub, common in shady places; for the beauty and sweetness of its flowers it is cultivated in gardens: its medical properties do not recommend it in practice, though some attribute extraordinary efficacy to it. The seeds are highly acrid; and, as their colour is alluring, children are often injured by eating them.

CAPRIMU'LGA, (from *capra*, *a she goat*, and *milgeo*, *to milk*; so called because it was supposed to suck the milk from the goats in the night time). It is a large kind of viper, not poisonous.

CA'PSICUM, CA'PSICUM A'NNUUM, (from *καψα*, *a bag*, from the shape of its pods). See PIPER INDICUM.

CAPSULA, (a diminutive, from *capsa*, *a little bag* or *case*, or *chest*). In surgery it is a bag made of the broken or distended membrana cellularis, or other membrane, formed by nature to inclose or lodge some extravasated juice, or other matter contained in those tumours called encysted; the same with *cystis*. But in botany it is the short pod, or husk of a plant, containing the seed. According to the number of cells for seed, the pod is called unicapsular, bicapsular, &c. It has several membranes of which it is composed. 1st, The outer coverings called *valvulae*. 2d, The partitions, *dissepimenta*. 3d, Central pillar, *columella*. 4th, Cells, *loculamenta*.

CAPSULA COMMUNIS GLISSONII, VE'NÆ PORTÆ. It is a production of the peritoneum, including the vena porta and biliary duct in the liver. It is also called *vagina portæ*. Glisson first described it particularly.

CAPSULA CO'RDIS. See PERICARDIUM.

CAPSULÆ ATRABILA'RIÆ, RENALES. Also called *glandulae supra renales, et renales; renes succenturiati*.

They are two little, oblong, flat bodies, lying at the upper end and inside, or the extremity of each kidney;

the right behind the vena cava, and the left behind the spleen and pancreas, being attached by vessels to those of the kidneys. When cut into, there seems to be a small cavity, containing a deep green fluid; and if viewed when fresh, a white substance where the vessels ramify; the inner part is a tender substance like the liver, so that it readily breaks down. Both the external and internal parts are vascular, and two or three large vessels may be observed in the middle. Eustachius was the first who described these glands. They are larger in the fœtus than in the adult, but their use is not certainly known.

**CAPSULÆ RES ARTERIÆ**, (from *capsula*). The arteries of the renal glands are thus called, because they are inclosed by a capsule; and arise from the aorta, above the arteria renalis, and give out the arteriæ adiposæ, which go to the fat of the kidneys. Sometimes they come from the trunk of the cœliaca. The right *capsular artery* comes, most commonly, from the arteria renalis, of the same side, near its origin; the left from the aorta above the renalis.

**CAPSULÆ RES VENÆ**, are branches from the emulgents, and go into the renal glands.

**CAPSULÆ RES SEMINALES**. The extreme parts of the vasa deferentia, which have their cavities dilated like *capsules*. Their use is to transmit the semen from the testes to the vesiculæ seminales.

**CAPSULARIA LIGAMENTA**, (from the same). **CAPSULAR LIGAMENTS**, also called *mucilaginous ligamenta*, as they contain many glands to separate the synovia. Every articulating bone is furnished with a capsular ligament, composed of two layers; the external is the stronger, being made by the periosteum; the inner is thin and uniform.

The use of the capsular ligament is, 1st, to connect the bones, which is performed by the outer lamella; 2dly, to confine the synovia, which is the office of the inner layer.

They are long and large in those bones that are designed for rotation, to give room for motion; and tendons are frequently inserted into them, that by their action they may draw them outward, and prevent their being compressed.

They are generally of an equal thickness all round in the enarthrosis and arthrodia; but in the ginglymus they are thick on the sides, and thin on the fore and hind parts, as in those places their thickness would have been inconvenient, by hindering the due flexion and extension of the joint; but the tendons strengthen the joint in that part, and partly compensate for the weakness of the ligament. In complete luxations, the capsular ligament is generally, if not always, ruptured. That of the os femoris is extended from below the neck of the bone, to admit of a more extensive rotation.

The capsular ligament of the head of the humerus proceeds from the edge of the glenoid cavity in the scapula; is continued over the head of the os humeri; fixed near its edge towards the muscular surfaces of the great and small tuberosities, and runs down on the neck of the bone, below the lowest part of the cartilaginous hemisphere. In all this course, the capsular ligament is closely fixed in the bone, except a small portion, where it passes over the inner articular tendon of the biceps muscle.

The capsular ligament always includes the whole joint. On collections within the capsular ligaments of the joints, see Bell's Surgery, vol. v. 485. On concretions and preternatural excrescences within the capsular ligaments of the joints, see Bell's Surgery, vol. v. 491.

**CAPUR**. (Arabic.) See **CAMPORA**.

**CAPUS**. See **CAPO**.

**CAPUT**, (from the Hebrew term *kabah*, an *helmet*). The **HEAD**. The parts in the lower cavities are the seat of the vital, and in the upper, of the animal powers; the latter is the seat from whence all sensation is derived. See **CEREBELLUM** and **CEREBRUM**.

Besides the external integuments of the head, there is an aponeurotic expansion which covers it like a cap. It is also spread round the neck and on the shoulders like a riding hood; for which reason Winslow calls it *coif*, and the superior portion of it the **APONEUROTIC CAP**. It is very strong, and appears to be made of two strata of fibres crossing each other; as it spreads to the neck it becomes thinner, and is lost insensibly on the clavicles. It sends out a production on each side from above downward, and from without inward, which having passed over the superior extremity of the musculus mastoideus, runs behind that muscle toward the transverse apophysis of the vertebræ of the neck, where it communicates with the intertransversalia ligamenta. See **PERICRANIUM**.

The head comprehends the cranium and the face; the cranium is distinguished into the upper and lower parts. The base of the skull externally is very uneven; internally it is divided into three pair of cavities, and one azygous cavity. The first pair are above the orbit, in which the anterior lobes of the cerebrum are placed; and the next pair contains the middle lobes; the posterior pair are placed behind the foramen magnum occipitale, where the posterior lobes of the cerebellum are lodged. The azygous cavity is situated upon that part of the sphenoid bone called the ephippium, or sella turcica, where the glandula pituitaria lies.

The bones of the upper part of the cranium are nearly of the same thickness. Where the bone is thick there is a larger space occupied by the medullium, which consists of cancelli, formed by the interlacing fibres, as in the heads of the long bones; where they are very thin there is no medullium, whence in the latter case the cranium is transparent, in the former opaque. The cranium is laterally depressed, which serves to enlarge the sphere of vision, and to increase the strength of the skull on its fore and hind parts, by making them more convex; which is a necessary contrivance to prevent injuries from falls, for we seldom fall on the sides. See **FACIES** and **CRANIUM**.

The best way of forming a perfect idea of the bones of the head is to have a skull, the bones of which are separated by art; and another, in which they are connected in their proper articulations.

The nerves from the fifth pair, and the portia dura, so called from its former consistence, of the seventh, are distributed through the external parts of the head.

Through the small foramina of the os ethmoides the

filaments of the first pair of nerves pass to the nose, and are called olfactory nerves.

In the os sphenoides, immediately behind, is the foramen opticum, through which the second pair of nerves, called the optic, pass. This hole, which is seated below the anterior clinoid process, likewise admits the branch of the carotid artery that goes to the eye.

The foramen lacerum superius on each side lies between the transverse spinous, and orbital processes of the os sphenoides: through this hole the three pair of nerves, called motores oculi; the fourth pair or pathetic; the first branch of the fifth pair; the whole sixth pair, except one reflected branch; and an artery from the internal carotids, pass to the orbit.

Behind the last mentioned hole, in the same bone, is the foramen rotundum, through which the second branch of the fifth pair of nerves, called the superior maxillary nerves, pass to the bottom of the orbit.

Between the pars petrosa of the os temporis, and the process of the os sphenoides, is an oblong aperture, through which the carotid artery passes, running inwards and upwards to the sella turcica, and thence to the clinoid processes, where it passes through the dura mater.

The portio mollis of the seventh pair of nerves, called the auditory nerve, is distributed to the meatus auditorius internus; the portia dura comes out by the aqueduct. The eighth pair of nerves, called the par vagum, pass out by that common hole, between the temporal and occipital bones; where likewise the internal jugular vein, which is a continuation of the transverse sinus, goes out of the cranium.

The ninth pair of nerves pass through the holes of the occiput above the condyles.

The tenth pair of nerves pass through the foramen magnum, where likewise the vertebral arteries enter.

The external eminences are, the two mastoid processes, the two styloid processes, the two condyloid processes, the two pterygoid, the two arches called zygomata, the external spine of the occiput, the condyloid and coronoid apophyses of the lower jaw.

The principal uses of the bones of the head are, to contain the brain, to be the seat of the organs of sensation, to serve for mastication, respiration, and the formation of the voice. There is sometimes a disorder of the head, which draws it to one side, called *contorsio*.

Eustachius' tables of the bones of the head are good. See Winslow's Anatomy, and Monro's Osteology.

CA'PUT. See CAPITA, and PROCESSUS.

CA'PUT CONCU'TIENS. See INTERTRANSVERSALES SOLLI.

CA'PUT GALLINAE. See ONOBYCHIS.

CA'PUT MO'NACHI. See DENS LEONIS.

CA'PUT MO'RTUUM. A DEAD HEAD. In chemistry it imports the dry faeces left in a vessel after the moisture hath been distilled from it. It is also called *terra damnata*, and *mortua terra*. The earthy part of moist bodies serves as a basis to the other principles; it is that which unites and gives them solidity. When the active principles are extracted, it is consequently called *caput mortuum*.

CA'PUT OBSTIPUUM. See CERVIX.

CARA BRASILIENSIBUS, called also *igname* *Canhamé*; *battatus Hispanica*. It is a name given by the

old Roman authors to a plant with large and esculent roots. The soldiers of Cæsar are said, in some of their marches when distressed for provision, to have made a sort of bread of this root; and P. Ægineta and Dioscorides inform us that this plant was of the *fastinaca*, or parsnip kind. It was probably the *elophoboscum*, or wild parsnip, which has roots long and thick, and of as good a taste as those cultivated in gardens, only they were not quite so tender. It is supposed that our word carrot is derived from this CARA.

CA'RAB. See SILIQUA.

CARABA'CCIUM LI'GNUM. The wood tastes like cloves, but very mild, and quite grateful, of a cinnamon colour. It is brought from India, but not much known in practice. Baglivi thinks that it corrects acrimony, and a scorbutic dissolution of the blood. See CASSIA CARYOPHILLATA.

CA'RABE, (from *carab*, to offer, Pers). See SUC-CINUM.

CA'RABE FU'NERUM. See BITUMEN.

CA'RABUS, (from *καρα*, the head; from *πατα* to *καταβαίνειν*, according to Schrevelius, it walks upon its head). This word is variously understood; with some it signifies an insect of the beetle kind, or those which are bred in dried woods, and belong to the scarabæi; with others, the cray fish; and sometimes it is used for the locusta marina.

CA'RABUS, CHRYSOCÉ'PHALUS, and FERRU'GINEUS of Fabricis. These insects have been recommended for the tooth ach. They must be pressed between the fingers, which must then be rubbed on the gum and tooth affected.

CARACO'SMOS. A name of the sour mare's milk which the Tartars are fond of.

CARA'GNA. See CARANNA.

CARA'MBOLOS. (Indian.) *Averhoa carambola* Lin. Sp. Pl. 613. This tree bears fruit three times in a year. It grows in the East Indies. To its different parts are attributed as many medical virtues. The fruit is agreeably acrid, and recommended in bilious fevers and dysenteries. Raii Hist.

CARAME'NO. See HYBOUCOUHU AMERICANUS.

CARA'NNA. (Spanish.) Also called *caragna*; *bre-lisis*. It is a concrete resinous juice brought from New Spain, and other parts of America, in little masses, rolled up in the leaves of flags, outwardly of a dark brown colour, inwardly brown, with a cast of red, variegated with irregular white streaks, somewhat soft and tenacious as it first comes over, but in time growing dry and friable. The whiter the gum, the better it is, especially if of the consistence of a plaster. Its virtues are the same as those of *tacamahaca*, but more active. It hath an agreeable smell, with a bitter and slightly pungent taste. Rectified spirit dissolves three-fourths of it, and water dissolves the rest, except the impurities. By distillation it affords much essential oil of an orange colour. It is fragrant, and to the taste moderately pungent. If the spirituous tincture be inspissated, it yields a tenacious resin, and an oily matter, which separates and floats on the surface: it is considerably aromatic, and moderately bitter. Etmüller says, that this gum is useful against pains in the stomach, and in the joints, if applied in the form of a

plaster. The tree which affords it is unknown. It is suspected to be a palm. See Lewis's Mat. Med.

CARA'NTIA. See SILIQUA DULCIS.

CARA-SCHU'LLI. (Indian.) *Frutex Indicus spinosus*. An Indian shrub like the caper bush. A decoction of the root provokes urine. Raii Hist.

CARAVA'TA. See CACAO.

CARBASUS. (Greek.) Scribonius Largus uses this word to signify the thin linen, or soft threads, on which the surgeons spread their ointments, viz. LINT; called also *achne*, *carfia*; in France, *charpie*; in Scotland, *caddes*. It is called likewise *linteum*, *linen*, *tents*, *rollers*, *compresses*; *moros* is an appellation for *lint*, whence *diamotosis*, the introduction of lint into a wound or ulcer. Where lint is applied to absorb the matter from a wound, pledgets of fine sponge are more effectual, and should be preferred where any inconvenience is apprehended from the sharpness of the matter.

CARBO, (from the Hebrew term *charak*, to burn, or *charbah*, burnt). But charcoal is generally understood by this word when *fossilis* is not joined with it. It is also a name of the *carbunculus*.

CARBO FOSSILIS, (from *charbah*, burnt). PITCOAL, or SCOTCH COAL. Hoffman says, that when it is analysed by distilling in a retort, over an open fire, it first yields a phlegm, then an acrid sulphureous spirit, then a subtle oil, then a grosser oil, which falls to the bottom of the receiver; then, by a brisker fire, an acidulated salt, like that of amber; in the retort there is left a black earth that is light, and which, on the application of fire, emits neither flame nor smoke. The gross empyreumatic oil contains a quantity of mineral sulphur: thus coal, as all bitumens are, is an oleo sulphureous acid, with a light calcareous earth.

These coals are only used for the advantage of their heat by burning them in stoves; but for purposes not connected with medicine, they undergo a process previous to their being used, that is, they are charred, or reduced to COAKS or CINDERS: this is effected by a method similar to that of making charcoal of wood: by this operation they are deprived of their phlegm, their acid liquor, and much of their fluid oil.

CARBO VEGETABILIS, or CHARCOAL OF WOOD, is the coal into which wood is converted by the process of charring.

Pieces of wood are so disposed as to form a pile, generally conical; this pile is covered with turf, to prevent the too free draught of air, by which the wood would be reduced to ashes, and not to coal. The pile is then kindled, and the fire continued till the watery and the more volatile parts of the wood are dissipated, that is, till no more smoke arises, at which time the wood is thoroughly red hot. The external air is then to be totally excluded by covering the pile with earth, and thus the fire is extinguished.

In chemistry, by the word *coal* is understood any substance containing oil, which hath been exposed to fire in a close vessel so that it can sustain a red heat without further decomposition; but the use of these coals or coaks in smelting iron is scarcely a part of our subject, and must not detain us at this time. Charcoal is of very considerable service in many processes connected with diet. From the indestructible nature of charcoal, charring the inner surface of casks

renders them more fit for preserving water; and, from some late experiments, it appears that water may be kept at sea without any change for an indefinite period, by this simple previous operation on the staves. Honey is cleared from its bad colour, and occasionally offensive taste, by its means; ardent spirits are deprived of an empyreumatic, or other bad flavour, and rancid oil by an admixture of charcoal is restored to its former state of purity. Vinegar concentrated by freezing, and afterwards distilled from powdered charcoal, becomes highly pure and fragrant. Crystals of tartar are whitened, and many of the neutral salts crystallize more perfectly, by previously digesting their solutions with this substance.

Heated charcoal absorbs air very completely, and forms a more perfect vacuum than the best air pump. In other circumstances it absorbs it in part only, preferring the oxygenous part to the azote. Cold charcoal absorbs atmospheric air without any decomposition. Fresh made charcoal absorbs water very copiously, and deposits a great part of the air it had taken up. It is an excellent conductor of electricity.

In medicine it is used as an application to cancers, and to putrid ulcers; occasionally also as a dentifrice, but it appears to possess little peculiar merit.

Charcoal from different woods are preferred in different arts, but its use in medicine and pharmacy is the same from whatever source it be obtained.

The vapours that arise from charcoal are extremely pernicious, producing a species of apoplexy in those persons who are exposed to them. They produce at first a sense of uneasiness, a chilliness, nausea, and headach. These are followed by a loss of sense, a fixed look, a rigidity of the whole body, a ghastly countenance, a small, frequent, and irregular pulse, and death.

In this case the noxious vapours act on the brain and nerves, through the medium of the lungs; these vapours, and those from fermenting vegetables, putrefying animal substances, or from caverns, operate in the same manner; and as accumulated and confined, their effect is more or less instantaneous. They attack the vital principle, and extinguish it at once if copious: a less quantity produces the symptoms of debility in the nervous system. To prevent suffering from this cause, close rooms where these substances are burning must be avoided; they are only safe when a candle will continue to burn in them. The vapours of deep wells are of this kind, but those of mines are different, and consist of hydrogenous gas. In some kinds of azotic gas, which are highly deleterious, a candle will burn freely.

When affected, the patient must be exposed to the open air; if he can swallow, acidulated liquors may be given: if he is insensible, cold water must be thrown on his face; strong vinegar rubbed about his nostrils, and held under them; stimulating clysters are also necessary. To remove the spasms, the *sps. atheris vitriolicus compositus* will be useful. If these fail, let a strong healthy person breathe forcibly into the mouth of the patient so as to distend his lungs, or they may be distended more advantageously by oxygenous gas.

CARBON, or CARBONE. This substance has not yet been procured in a separate state; the idea of it is an abstract, not a sensible one: yet it is not, like phlogiston, an imaginary principle, for though on the whole

the evidence of its existence is not more strong, it does not by its presence involve any contradictory quality.

The essence of carbon has been thought to consist in its absorbing light, and appearing of a black colour; but the purest form in which it is offered to our observation is that of the sparkling diamond. In the carbonic acid gas it is combined only with oxygen, for Lavoisier found that this gas contained 28 parts of carbon, and 72 of oxygen. Charcoal itself, is supposed to be carbon, with a smaller proportion of oxygen; and diamond approaches still nearer to the carbon: so that charcoal has been called an oxide of diamond.

Carbon unites with many bodies, which are denominated carbonates and carburets. It does not, however, combine in the form of charcoal with oxygen gas, till its temperature be raised to 370° of Fahrenheit, its point of ignition. It then burns in this gas with a brilliant flame, and the carbonic acid gas is the result. This gas also escapes in respiration, and in many other animal processes. In the form of carbonic acid, it exists copiously in the earth, united with limestone, and is found in many other bodies. It occurs alone in caverns, and particularly in the grotto del Cani in Sicily.

It particularly engages our attention in this work, as it is the distinguishing ingredient in vegetable bodies, while the azote equally discriminates animal substances. It is derived from the earth, for of whatever kind manures are, they all contain carbon, or greedily extract it from the air. From thence it is introduced into the animal system; and, combining with oxygen, is discharged in respiration in the form of carbonic acid gas. We have already noticed this change, particularly under the article of CALIDUM INNATUM, and shall return to it under that of RESPIRATION. In the system it produces no particular effect. In the stomach, as we have seen under the head of AQUE MINERALES, it acts as a stimulant, and relieves vomiting.

CARBONAS. CARBONATE. Salts formed by the union of carbonic acid with different bases; as *carbona cupri*, carbonate of copper.

CARBO'NICUM A'CIDUM. Carbon united with a larger proportion of oxygen than in charcoal, see AER.

CARBOS. CANAL COAL. See AMPELITIS.

CARBU'NCULUS. A CARBUNCLE, (from *carbo*, a burning coal). It is called *carbo, rubinus verus*; *code-sella*, *erythema gangrænosum*, *granatristum*, *anthrax*, *pruna*, and Avicenna names it *Persicus ignis*, particularly that species which is attended with pustules and vesications. Paulus Ægineta says it is a crusty ulcer, beginning, for the most part, with a pustule like a burn, and sometimes without it; at first, the patient scratches the part, whence arise one or more pustules, small as a grain of millet, which, breaking, become a crusty ulcer, as if it was produced by an actual cautery; the crust is rather of an ash colour or blackish; it adheres, and is fixed on its base to the part, and spreads by its phagedenic property; the flesh all around is inflamed and black, and shines like bitumen. Heister says, a carbuncle is an inflammation, which, in pestilential times, rises with such vesicles as are the usual effects of a burn; this inflammation, for the most part, suddenly degenerates into a sphacelus, and corrupts the subjacent parts to the bones, rendering them as black as a coal; and this seems to be the reason why

the Latins call them *carbunculi*, and the Greeks *anthraces*.

In the Edinb. Med. Commentaries, vol. vi. p. 165, it is observed that carbuncles are a gangrenous spot upon the skin, having the appearance of a burn with red, livid, or black vesicles, bounded by an inflammatory ring, which soon terminates in a hard black eschar. The anthrax, an affection of the same nature with the carbuncle, only the former is more prominent, penetrates deeper into the adipose membrane, and occasions a higher degree of inflammation.

Dr. Cullen places it as a variety of phlogosis erythema, on account of its violence, making it synonymous with anthrax, and the erythema gangrænosum of Sauvages. Carbuncles generally break out suddenly and unexpectedly, in an hour or two at the most, and are attended with pain and heat. The inflammation proceeds so quickly to mortification, that there is seldom any evident tumour raised, the parts turning black, and ending in real gangrene, often in the course of twenty-four hours from the first attack. But when a tumour does arise, as soon as it is opened, it discharges a livid sanies, or sometimes limpid water. It is black within, which shows that a sphacelus has seized the subjacent flesh, and is making rapid progress. In those that recover, a separation is made betwixt the sound and the disordered flesh, by means of a suppuration. There is no part of the body but what may be their seat; and they are generally attended with buboes. The proximate cause is the inflammation from pestilential contagion, with a putrescent state of the system. Danger is great when the colour is livid; the milder sort are first red and then yellow. When they are seated on the face, neck, breast, and arm pits, they are generally fatal. When they occur, as they sometimes do, internally upon any of the viscera, they must, in every instance, probably prove fatal, as we are not acquainted with any remedies which can ever prevent their progress to mortification. Externally, indeed, when they are not very extensive, nor seated on any of the large blood vessels and nerves, they are frequently conquered, that is, by the destruction of the part affected.

Van Swieten describes another sort of carbuncle in his Comments on Boerhaave's Aphorisms; and says, it is an ulcer, which, when after a violent and commonly very painful inflammation, there happens a rupture of the skin in several places, and fragments of the corrupted panculus adiposus are discharged at its orifices.

In the view we have thus given, carbuncle appears as a putrid, irritable sore, whose origin is in the cellular substance, and which is intimately connected with putrid or pestilential diseases, the production of a hot climate, or the attendant of weak debilitated constitutions. Anthrax, however, as observed in this country, assumes a different form. A hard substance forms in a fleshy part, often in the back or thigh, with a violent throbbing pain and a burning heat. It frequently happens to old persons, and sometimes seems to be a critical deposition, an effort of nature to discharge some morbid fluids. This hard body suppurates with difficulty, and imperfectly; but if the constitution is sufficiently strong to carry on the process, the whole is separated, and the cavity fills with healthy granulations; the constitution regaining its strength, often with reno-

vated vigour. It happens, however, frequently in the weak and aged; in persons loaded with fat, and often breathing with difficulty. The latter can seldom bear the tonic powers of bark without suffocation, and to the former any dose of bark or any cordial is generally insufficient. They yield to the discharge, or sink more rapidly from sphacelus.

The substance of this hard tumour seems to be a congeries of the sebaceous glands under the skin, for if on the first appearance of the tumour, the point, which is obvious, be opened, and the tumour gently pressed, a quantity of sebaceous matter is forced out. The throbbing and heat, however, soon return, and the operation must be often repeated. We have frequently, in this way, checked anthrax in its germ.

It more often happens that the tumour is suddenly formed of a considerable size. If this be the case, or the pressing out be neglected, suppuration goes on; not indeed in the tumour, for the sebaceous matter does not admit of this change, but in the parts around, and the tumour is then thrown out like a cancer by the effect of arsenic. The cavity is generally large, and the discharge considerable: few constitutions are equal to it, especially when debilitated by age, the previous fever, and the violent pain.

Every stimulant application externally, and the warmest tonics, with wine and opiates internally, are requisite. Yet these, as we have said, are often useless, or unequal to support the patient under circumstances so violent and distressing. It has been proposed to make incisions into the tumour, and to fill it with stimulating substances; but we have never found this plan of service, for the tumour itself never suppurates. Might the application of corrosive sublimate or arsenic succeed?

See Heister's Surgery, Bell on Uleers, edit. 3. p. 97—99. Kirkland's Med. Surgery, vol. i. 320, vol. ii. 280, 389. Pearson's Principles of Surgery, vol. i. 136. White's Surgery, 15.

CARCA'PULI FRU'CTU MA'LO AU'REO Æ'MULO; CODDAMPU'LLI. (Indian.) The INDIAN YELLOW ORANGE TREE of MALABAR, called also *ghoraka*.

It is a tall large tree, with yellow flowers, and large round fruit, that is ribbed and whitish, when ripe of an agreeable acid and sweetish taste, and with seeds of an azure blue colour. This fruit recovers lost appetite, and is restringent. The same tree, however, affords the GAMBOGE, q. v.

CARCA'PULI LINCO'TANI. This differs from the above in its flower and fruit. The fruit of this species is sweet, round, and of the size of a cherry. It is also called *kanna ghoraka*. They both afford the gamboge, but this latter the best.

CA'RCAROS, (from *καρκαίρω*, to resound). See PHRICODES.

CA'RCAS. See CATAPUTIA, under RICINOIDES.

CA'RCAX, (from *καρά*, a head). A species of poppy with a very large head.

CA'RCER. Paracelsus means by it a remedy proper for restraining disordered motions of body and mind, as in curing the chorea sancti Viti.

CARCHE'SIUS. The name of some bandages noticed by Galen, and described by Oribasius. Properly,

a rope which goes round the top of a ship's mast, and keeps it steady on both sides.

CARCINE'THRON, (from *καρκινος*, a crab, so called from its being jointed like the claws of a crab). A name in Oribasius for the *polygonum*, or common knot grass.

CARCINO'DES, (from *καρκινωμα*, and *ειδος*, forma). A tumour resembling a cancer.

CARCINO'MA, and CARCI'NOS. See CANCER. It sometimes signifies the cancer only in its ulcerated state; or cancerous ulcer, however produced.

CARDAMA'NTICA, (a dim. of *καρδαμον*, *nasturtium*). See CARDAMINES.

CARDAME'LEUM. (Greek.) The name of a medicine mentioned by Galen.

CARDAMI'NDUM MINUS, (from *καρδαμον*, and *ινδος*, Indian cresses). See NASTURTIIUM INDICUM.

CARDAMI'NES, (from *καρδια*, the heart, because it comforts and strengthens the heart). Also called *cardamantica*, *nasturtium aquaticum*, *culi flos*, *iberis*, *herba veteribus ignota*, *sophia*; MEADOW CRESSES, LADIES SMOCK, and CUCKOW FLOWER. The *cardamine pratensis* Lin. Sp. Plant. 915. Nat. order *siliquosæ*.

The cardamine was formerly esteemed as a diuretic and sudorific, and then was supposed to be a powerful antispasmodic. It grows in meadows, and flowers in April.

Sir Geo. Baker, in the Lond. Med. Trans. vol. i. p. 442, relates a case of a spasmodic asthma, that after resisting all other means, was cured by taking the flowers of this plant, at first ʒ i. twice a day, and afterwards ʒ ss. in each dose. The chorea sancti Viti was cured by ʒ ss. twice a day. The case was obstinate while other means were used, but soon gave way to these flowers. To these he adds a case in which palsy, a difficulty of swallowing, and convulsions, were complicated; and though these disorders had been of long standing, relief was obtained by ʒ ss. of these flowers taken twice a day. He further observes, that they improve the appetite, that ʒ i. hath succeeded as an antispasmodic, where opium, camphor, and valerian failed; and that they have been given to ʒ iss. three times a day.

Greeding, though he tried this medicine in large doses in a great number of cases, experienced its good effect only in one. We have never experienced them in one.

Linnaeus observes, that these flowers are pungent to the taste, but their pungency is inconsiderable; and they have scarcely ever succeeded in our hands as an antispasmodic, nor have they seemed to possess any medicinal powers. Dioscorides says, they are warm and diuretic; Galen, that they resemble water cresses in taste and virtues; Dale, that they are antispasmodic; and Dr. T. Robinson, that they are powerfully antiepileptic.

Dr. Cullen mentions this plant, and particularly its flowers, to be far inferior to several others of the *siliquosæ* in its sensible qualities; and he noticed them only on the authority of Sir Geo. Baker, referring to his paper on this subject above quoted.

CARDAMO'MUM, (from *καρδαμον*, and *αμωμον*, because it participates of the nature of both). The COMMON OR LESSER CARDAMOMS, called also *elettari*.

*cardam. minus.* The lesser cardamom seeds are the produce of the *amomum cardamomum* Lin. Sp. Plant. 2. But later authors have referred it to another species, the *a. repens* of Willdenow, vol. i. page 9. Nat. order *scitamineæ*.

Cardamoms are a dried pod with seeds, brought from Malabar in the East Indies: the best come from Comagene, Armenia, and the Bosphorus. They grow also in Arabia. These pods are divided internally into three cells, in each of which are two rows of triangular seeds, of a brownish colour on the outside, and white within. The plant grows in the form of our reeds.

The lesser cardamoms have short triangular husks, scarce half an inch long. The seeds freed from these husks are a grateful aromatic, warm, but not fiery, and not subject like pepper to create immoderate heat. The husks should only be separated when used; for the seeds lose much of their flavour if taken out. They give out all their virtue to spirit, and nearly so to water. In distillation with water, a large quantity of essential oil rises; it is pungent to the taste, and smells strong of the seeds; the remaining decoction is bitter and mucilaginous, but void of the flavour and warmth of the seeds. A spirituous tincture, when evaporated, leaves the virtues of the seeds almost wholly in the extract, which is more grateful than the seeds themselves. They are considered as gentle stimulants of the stomach, cordial, carminative, and antispasmodic; without that irritation and heat which many other of the spices are apt to produce. All the spirituous preparations are more agreeable than the watery.

The TINCTURE OF CARDAMOMS is made by digesting three ounces of the bruised seeds in a quart of spirit for eight days. It possesses all the virtues of the seeds; and among all the aromatics there are none that answer so well, in general, as this tincture, for rendering mineral waters and other saline liquors easy and agreeable in the stomach. The dose is one drachm to three.

COMPOUND TINCTURE OF CARDAMOMS, formerly *tinctura stomachica*, is made of smaller cardamom seeds husked, caraway seeds, cochineal, of each powdered two drachms; cinnamon bruised, half an ounce; raisins, stoned, four ounces; proof spirit, two pints; digested for fourteen days, and strained. This is often ordered by itself, or in draughts, from two drachms to half an ounce, joined with æther, and tinct. opii, in gouty and other spasmodic affections of the stomach and precordia.

CARDAMO'MUM MAJUS. The GREATER CARDAMOMS. The *amomum grana paradisi* Lin. Sp. Pl. 2. Their pods are about an inch long, triangular, and with two rows of seeds in each. The husks are tough, and thicker than those of the lesser kind. They grow in Java and the East Indies.

CARDAMO'MUM MEDIUM, grows in pods of a round figure. These two, though of the same nature, are weaker than the first kind, and consequently disused. See Cullen's Mater. Medic. Woodville's Medic. Botany.

CARDAMO'MUM PIPERATUM. See PARADISI GRANA.

CARDAMO'MUM SIBIRIENSE. See ANISUM INDICUM.

CARDEGI INDI. See FOLIUM.

CARDIA, (from καρδιά, cor). By this term the an-

cients meant the heart; but we call the upper orifice of the stomach cardia, from its vicinity to, and consent with, the heart. See COR, CARDIALGIA, MEDITULLIUM, and LIPOTHYMLA.

CARDIACA HERBA. MOTHERWORT. It is also called *agripalma gallis*, *marrubium*, and *cardiaca crispa* Ruellii; *leonurus cardiaca* Lin. Sp. Pl. 817.

It is called *cardiaca* because it is supposed to relieve in fainting and disorders of the stomach, particularly in children and in hypochondriacs. It is biennial, grows waste in wild grounds, and flowers in July.

It hath been celebrated in disorders of the stomach, proceeding from thick phlegm. It is said to loosen the belly, promote perspiration, urine, and the catamenia. The leaves and tops have a strong, rather a disagreeable, smell, and a bitter taste, and it has probably been useful in hysteric affections. By keeping, or by boiling, the disagreeable smell is dissipated. An extract of a pungent bitter quality is obtained by evaporating the watery decoction. But an infusion of the tops before it flowers is the best preparation. See Dale, Miller's Bot. Off. Lewis's Mat. Med.

CARDIACA, CORDIALS, (from καρδιά, the heart and upper orifice of the stomach, because they act on the heart by their application to the stomach). In pharmacy it signifies CORDIAL, and is also named *cordialia*, *analeptica*, *resumptiva*, and by Paracelsus, *defensiva*.

The word *cordial* is of a large extent. Things of very opposite natures may prove cordials by relieving the same symptoms when produced by opposite causes. To understand their operation, it is necessary to consider that a languor or faintness may be the consequence either of what oppresses or of what exhausts the vital powers; what retards the progress of the vital principle, or impedes its influence, produces the same sensation as its diminution. In both these cases, medicines of opposite natures produce the same effect, by adding force to the fibres: thus, under an oppression of spirits, from heat, when no extraordinary action or indisposition of body hath exhausted them, a glass of cold water is a *cordial*, for it stimulates the fibres, and rouses them to their wonted action; and when, from violent exercise or a tedious disease a person faints, warm medicines, or aromatic and spirituous liquors, are also *cordial*, by producing the same effect. But in general, by *cordials*, is understood those preparations whose warm and active parts, immediately on being received into the stomach, produce a cheerfulness, and are suited to increase the strength and vigour of the heart. Valcarengus observes, that a *cordial* is whatever destroys, or at least blunts, the force of a morbid cause, restores the lost tone of the solids, and gives due motion to the fluids; by that means procuring a just equilibrium.

CARDIACA PASSIO. The CARDIAC PASSION is a disorder frequently mentioned by the ancients; but by the moderns it is mostly treated of under the name of SYNCOPE, and, indeed, from the description of the ancients, it may well be referred to that article. The name *cardiaca passio* is from the part supposed to be affected. Cælius Aurelianus says, "that this disorder, according to some, derived its name from the part affected; for they imagined that the heart is the principal seat of it." Soranus declines giving a

definition, and says, "that there is no perceptible sign of any tumour about the heart," which some suppose; and he asserts, "that it is a quick and instantaneous solution, or relaxation." Hippocrates mentions this disorder in his first and second books of Epidemics. Erasistratus also speaks of it in his books concerning the belly. Artinodorus Sidensis says, it is a tumour about the heart: but from the description of Cœlius Aurelianus, in his *De Acut. Morb. lib. ii.* the syncope is very clearly and accurately described. See LYPOTHYMIA.

CARDIACÆ ARTE'RIÆ, et VE'NÆ. See CORONARIÆ ARTERIÆ, et VENÆ.

CARDIACUS MO'RBUS. (Falconer in the *Memoirs of the Medical Society*, vol. vi.) See NERVOSA FEBRIS.

CARDIA'LGIA. THE HEARTBURN, or rather a pain and uneasiness at the upper orifice of the stomach; (from *καρδία*, the left orifice of the stomach, and *αλγία*, to be pained). Called also *ardor ventriculi*, and properly so, when attended, as it sometimes is, with considerable heat; likewise *cordolium*, pain or uneasiness about the upper orifice of that organ, and *cardiogmus*.

Dr. Cullen ranks it as synonymous with *dyspepsia*; and considers it as arising either from a disease of the stomach itself, or from an affection of some other part, or of the whole habit. SYNOP. NOSOLOG. METHOD. Gen. 45.

This disorder is called *soda*, *heartburn*, or *spurious cardialgia*; *pain in the stomach*, or *the true cardialgia*, also *cardimona*. In the SPURIOUS kind the pain is not so great, nor does the strength fail, nor is there any remarkable inquietude. In the TRUE, there is pain in the stomach, or about its upper orifice, but generally about the pit of the stomach: it is sometimes attended with great anxiety, difficulty of breathing, want of strength, inquietude, retching to vomit, coldness, and trembling of the extremities. Sometimes the uneasy sensation extends the whole length of the œsophagus, with a pressure or constriction, and usually attacks by fits.

The upper orifice is the usual seat of this disorder; it is sometimes in the lower; and is occasionally the disorder of the whole viscus. In those who have died of this disorder, on dissection the right orifice only hath appeared to be in an unnatural state.

Were we to be minutely exact, we should refer every cause of cardialgia to the weakened powers of digestion; since, if these are strong, no inconvenience arises from any aliment: so true is the axiom, *sanis omnia sana*.

To avoid, however, all minute disquisition, we shall refer the causes to a disease of the stomach and its contents, to a disorder of distant parts, or the whole system, with which this organ sympathises. The disease of the stomach, we have said, is weakness; and the disordered contents, from this cause, are acid, oily, acrid, or bilious substances, which its debilitated powers are unable to combine with the alimentary mass. Acid is generally accused, and the anti-cardialgics are generally alkalis and absorbent earths. It is, indeed, the most frequent cause, whether the disease be idiopathic or symptomatic. The acid swims on the surface of the contents of the stomach, and gives the sensation of burning heat to the cardia. It arises from

acescents, rather than acids; from fruit, vegetables, and saccharine substances. Oily foods are, however, an equally frequent cause. A red herring, for instance, will often produce it; the fat of meat, butter, and every similar matter will, in many constitutions, bring on the complaint, particularly if the process of digestion is disturbed in its commencement. Acrid is a term too general, yet it is meant to include highly seasoned dishes, pepper, and various spices, which have been long acknowledged as causes, though not frequent ones, of cardialgia. That bile in the stomach is a cause, we cannot so confidently affirm; yet it has been enumerated as such: and if heartburn is attended with a putrid taste on the back part of the tongue, the disease may be pronounced to arise from bile. We suspect, however, that the opinion has arisen from its being an attendant on jaundice; and we well know, that when bile, the usual neutraliser of acid, is absent, it may probably abound. In any circumstance, if the usual mucus of the stomach be abraded, or the organ inflamed, the most common and salutary aliménts may occasion this impression from the increased sensibility of the organ: thus it seems sometimes to arise from corrosive poisons; we have seen it from swallowing, by mistake, the volatile sal ammoniac; and in this way it is found to be the effect of inflammation and abscess in the stomach.

In general, as Dr. Hunter has supposed, it is the fumes of these substances rather than the substances themselves which occasion the complaint. The stomach is seldom perfectly full; and, though its action may sometimes raise the contents to the cardia, the contact must be only occasional and temporary.

The more general causes which affect the stomach by sympathy are gout and nephritic complaints. From a fact recorded by Van Helmont, it seems, that any affection of the joints may in this way disorder the stomach. Violent passions have equally produced it. Cold feet seem sometimes to have the same effect, and the relief is then generally preceded by a return of perspiration in the extremities. A recession of eruptions has been supposed to be a cause; and, as in such cases the stomach generally suffers, not without some reason.

To relieve the complaint, the diet should be light, generally of the animal kind: what is drunk should not be apt to ferment; brandy and water, or water in which toasted bread is steeped, will generally agree; or camomile tea, which soothes the spasmodic motions of the stomach. Lime water, the mineral alkaline waters, and distilled water, are proper for common drink.

The cure depends on the cause. As in every instance the stomach is weakened, bitters, and perhaps chalybeates with aromatics, should accompany the appropriate remedies. We need not repeat what we have said of antacids; but, in the heartburn from oily or acrid substances, immediate relief is obtained from sucking gum arabic. If it *should* arise from bile, vegetable acids will almost immediately remove it. Vomits are often advantageously premised.

When not arising from the contents of the stomach, general warmth, particularly of the feet, is essentially useful; and even rubbing them with flour of mustard has produced good effects. Tonics of every kind are

indispensable additions to the other remedies; and, when from gout, aromatics should be joined. In every species, also, the bowels should be kept free, and the warmer resinous purgatives are best adapted to the complaint. Any external applications that may be thought necessary should be placed on the pit of the stomach.

CARDIA'LGIA INFLAMMA'TORIA. See INFLAMMATIO VENTRICULI.

CARDIA'LGIA SPULATORIA. See PYROSIS.

CARDIME'LECH, (from καρδιά, *cor*, and the Hebrew term *melek*, a governor). A fictitious term in Doleus's Encyclopedia, by which he would express a particular active principle residing in the heart, appointed to what we call the vital functions.

CARDIMO'NA. See CARDIALGIA.

CARDINAME'NTUM, (from *cardo*, a hinge). A hinge-like articulation. See DIARTHROSIS.

CARDIO'GMUS, (from καρδιωσσω, to have a gnawing pain at the mouth of the stomach). Synonymous with Cardialgia.

CARDIO'NCHUS, (from καρδιά, the head, and ογκος, a tumour). See also ANEURISMA PRÆCORDIORUM.

CARDIOTRO'TUS, (from καρδιά, the heart, and τήρωσις, to wound). One who hath a wound in his heart.

CARDI'TIS, (from καρδιά, heart). See INFLAMMATIO CORDIS.

CAR'DO. A HINGE. See GINGLYMUS.

CA'RDONET. See CINARA SYLVESTRIS.

CARDO'NIUM, in the phrase of Paracelsus, is wine medicated with herbs.

CARDOPA'TIUM. See CARLINA.

CARDUO-CNI'CUS, (from *carduus*, a thistle, κνικος, *carthamus*, the distaff thistle). See ATRACTYLIS.

CA'RDUUS, (from κείρω, to abrade; so named from its roughness, which abrades and tears whatever it meets with). The THISTLE. The general characters of which are as follow: the leaves are set alternately on the branches, and are prickly; the heads are mostly squamous and prickly; prickles are on most or all parts of the plant, and they are mostly lactescent.

CA'RDUS BENEDI'CTUS. See BENEDICTUS. The BLESSED or HOLY THISTLE; also called *cnicus sylvestris*. It is the *centaurea benedicta* Lin. Sp. Pl. 1296. Nat. ord. *Composito capitatæ*. *Cynarocephali* of Jus-sieu. It is a native of Spain and some of the Archipelago islands, and is annually sown with us in gardens.

The leaves have a penetrating bitter taste, not very strong or durable in the mouth; when fresh they are more pleasant than when dry. The plant should be hung up loosely in an airy place after it is well dried; for, if pressed close, it rots. The best time for gathering it is when in flower.

This plant obtained the name benedictus from its being supposed to possess extraordinary medical virtues; but it is not found to excel several other of the simple bitters; though Bergius considers it as antacid, corroborant, stomachic, sudorific, diuretic, and eccoprotic. See AMARA.

Camomile flowers are now generally substituted for the *carduus benedictus*, and are thought to be of at least equal value.

When this herb is used to excite vomiting, a decoction of it in water is preferable, for thus its more nauseous parts are extracted: cold water, in an hour or two, imbibes a light grateful bitter; but if the infusion be continued much longer, the nauseous part is also taken up. Rectified spirit extracts only the agreeable bitter, and, though heated, it does not easily take up the offensive parts.

A light, cold, watery infusion, with fresh lemon or orange peel, improves the appetite, and is useful when the digestive powers are weak: it sits easy on the stomach, and no bitter is less heating. Dr. Cullen thinks this plant a simple and pure, though not a very strong, bitter; and that, therefore, it possesses none of the extraordinary virtues ascribed to it. An ounce of the dried leaves may be infused two hours in a pint of cold soft water, and it may be flavoured at pleasure with any aromatic. It may be made stronger by returning the liquor on fresh parcels of the leaves or tops. It affords nothing valuable by distillation. See Lewis's Mat. Med. Miller's Bot. Off. Dale.

CA'RDUS HÆMORRHODA'LIS. So called because it relieves the pains of the hæmorrhoids, if beat into a poultice and applied; also called *carduus vinearum repens*, *sonchi folio*, *cirsium arvense*, *ceanothos*; *serratulu arvensis* Lin. Sp. Pl. 1149. The COMMON CREEPING WAY THISTLE.

Its roots are whitish, but now and then are of a darker hue, and have a strong smell: it sends forth fibres that creep on the ground, and propagates itself to a great distance: it is common in tillage ground and highways, flowering in July and August.

CA'RDUS LACTEUS, also called *carduus Mariæ*, *carduus Marianus* Lin. Sp. Pl. 1153. *carduus albis maculis notatus vulgaris*. c. b. COMMON MILK THISTLE, or LADY'S THISTLE. It is distinguished from all other thistles in England, by having its leaves cut in several laciniae, full of hard sharp prickles, having all the upper part spotted with long and broad white spots. It grows on banks, and flowers in June. The leaves and seeds have similar virtues to those of the *carduus benedictus*, but in an inferior degree. It is said to be efficacious against pungent pains. Miller's Bot. Off.

CA'RDUS LACTEUS SYRIA'EUS, Lin. Sp. Pl. 1153. also called *carduus albis maculis notatus exoticus*. *Bede-guar Arabum Rauwolfii*, *cnicus albis maculis notatus*. The SPANISH MILK THISTLE.

This and the next species are perennial, have long, narrow, deeply jagged leaves, that are prickly and lying on the ground; in the middle of the plant grows a large roundish head, without any stalk, encompassed with smaller leaves, which may be eat like an artichoke; the flowers issue from the middle of the head.

CA'RDUS PINEA THEOPHRASTI; *carlina aulos gum-mifera*, *chameleon albus Dioscoridis*, and PINE THISTLE; *atractylis gummifera* Lin. Sp. Pl. 1161. Its flowers are composed of purplish flosculi, like those of the common thistle. It is a native of Italy and of Candy. Its roots are larger than those of the carline thistle, and smell stronger; if wounded when fresh they yield a viscous milky juice, which concretes into tenacious masses, at first whitish, and resembling wax, when much handled, growing black; supposed to be the *ixion*, *ixia*, and *acanthina mastiche* of the ancients; the people of

Apulia gather this gum, and name it *cera di cardo*. It was formerly chewed for the same purposes as the mastich gum: the root hath the same virtues as the carline thistle roots.

CA'RDUUS SPINOSISSIMUS *sphærocéphalus rigidis aculeis armata*; c. b. *cârdui Arábici*, PARK. THEAT. *spîna Arábica offic.* ARABIAN THISTLE. *Carduus nutans* Lin. Sp. Pl. 1150. It seems to have qualities similar to those of the spina alba.

CA'RDUUS A'CANTHUS. See ACANTHUS.

CA'RDUUS BRASILIA'NUS FO'LII A'LOES. See ANANAS.

CA'RDUUS A'LITILIS; *domesticus; sativus, non spinosus; sativus*. See CINARA.

CA'RDUUS HUMILIS GUMMIFERA. See CARDUUS PINEA.

CA'RDUUS LUTEUS. See ATRACTYLIS.

CA'RDUUS SOLSTITI'ALIS. See CALCITRAPA OFFICIN.

CA'RDUUS SATIVUS. See CARTHAMUS.

CA'RDUUS STELL'ATUS. See CALCITRAPA.

CA'RDUUS STELL'ATUS LUTEUS. See CALCITRAPA OFFICIN.

CA'RDUUS ESCULENTUS; *spinosissimus elatior*. See CINARA SPINOSA.

CAREBA'RIA, (from *καρη*, the head, and *βαρος*, heaviness). See CAPIPLENIUM.

CARE'NA. The twenty-fourth part of a drop.

CARE'TTI. See BONDUCH INDORUM.

CA'REUM, CA'RI. (See CARUM.) From *Caria*, the country from whence they were brought.

CA'RICA. A DRY FIG, (from *Carica*, the place where they were cultivated). See FICUS SATIVA.

CA'RICUM, vel CA'RYCUM, (from *Caricus*, the inventor). The name of a medicine for deterring ulcers, prepared of the black hellebore, cantharides, and several other ingredients.

It is also the name of an oil mentioned in Athenæus, lib. ii.

CA'RIES, (from *καρη*, to abrade, or from *karah*, to dig in, a Chaldee word); according to Mr. Sharp, it is a partial mortification of the bone, which separates from the sound part sooner or later. Dr. Cullen places this disease in the class *locales* and order *dyalyses*, and names it *exulceratio ossis*. But as every species of *caries*, attended with loss of substance, may be termed an ulcer, Mr. Bell, to prevent confusion, considers *caries* as an accidental symptom of ulcers, and speaks of it under the general name of CARIOUS ULCER. It is an ulcer, however, of a gangrenous kind, but differing from mortification of the bone, which will be considered under the term NECROSIS. In short, these diseases bear the same relation to each other as a foul putrid ulcer and a sphacelus.

This disorder, called *caries*, *sphacelus*, *teredo*, or *treton*, happens when the bone is deprived of its periosteum, and, having lost its natural colour, becomes oily, yellow, brown, and at last black. This state, which is the first degree of the disorder, was called by the ancients OS VITIATUM, OSSIS NIGRITIËS. When the disease advances the bone is corroded, discharging a sanies which consumes the adjacent flesh. Of the many names given to the *caries*, which are collected under *spina ventosa*, the following are only necessary: When the cause is external, it is the SPINA VENTOSA; or, with Severinus, when it happens to children, it may

be called PÆDARTHROCAÏES: when the cause is external, *caries*.

That an inflammation of the periosteum is tending to a *caries* of the bone, is known, first, *from the signs of inflammation preceding*; secondly, *a freedom from pain in the affected part, without a manifest cause, and from a dense, slow, increasing, and not very painful, tumour of the incumbent parts*. But among the signs of a beginning *caries*, the sudden removal of pain is fallacious; for this happens in inflammation of the periosteum, when this membrane is corroded so as to admit the matter to escape betwixt the muscles, though, in general, when pain is relieved by a resolution of inflammation, it goes off gradually only; for a perfect resolution hardly, if ever, happens after a violent inflammation. Again, when a *caries* is threatened, the taint is propagated through the cellular membrane, which, by slight causes, is often raised into a large tumour: but, as all the symptoms of an inflammation lessen when a *caries* is present, the tumour will not have the hardness and resistance observable in a phlegmon, but will be flaccid, and hardly sensible of pain. If the incumbent part changes to a livid colour, or a dark sanious discharge issues from a part in the direction of a bone, the bone is then, without doubt, in a mortifying state.

Celsus, the best ancient author, at least on the cure of *caries*, observes, lib. viii. cap. 3. "We may soon, by means of a probe, discover a *caries* of the bone, since the probe will penetrate less or more, according as the *caries* is superficial or deep." When the probe comes to the sound part of the bone, it is resisted. Wiseman, vol. i. p. 296. edit. 5. says, "If the bone be bare, its corruption is easily discerned, though sometimes it be covered with a grumous or viscous matter, which rubbed off, the bone appeareth white, brown, or black. If the white be porous, the *caries* may be deeper and more dangerous than if it were black and hard. If the bone lies so hid as that you cannot feel it with your probe, yet you may judge it carious from the quantity or quality of the matter. If the bone lies near, and the flesh is lax and white, it is strongly suspicious that the bone is carious: but if the matter stinks, or is oily, it is a more certain sign of rottenness. Ulcers of long continuance near a bone do also foreshow a *caries*, according to Hippocrates. Also the difficulty of cicatrizing them, and the frequent and sudden eruption of them after they are cured, give a suspicion of a foul bone. But if the bone is much corrupted, the matter is fetid, and the probe will penetrate into it."

The friability of carious bones is occasioned by the acrimony of their humours, and chiefly of their corrupted medullary oil; for since its separation destroys the cohesion, by decomposing the bony substance, the peculiarly disagreeable fetid smell, which arises from carious bones, is from this corrupted medullary oil.

When a *caries* is under an ulcer, the flesh over the *caries* is soft, flaccid, and fungous; the lips of the ulcer inverted, the sanies clear, fetid, and full of small black scales. The ulcer heals only superficially, and soon breaks out again. Ulcer has been accused of producing *caries*, but the latter is more frequently the cause of the former. See ULCER with a *caries*, under ULCUS.

In the Edinb. Med. Essays, Dr. Monro gives a par-

ticular account of several species of this disorder, viz. 1. The DRY OR GANGRENOUS CARIES, which is, where the bone is smooth and firm, and throws out little matter; its surface at first is not of a very dark colour, but before exfoliation it turns very brown or black. This kind exfoliates with less difficulty than any other. 2. The WORM EATEN CARIES, or ULCER of the BONES, hath not such a dark colour as the former, it discharges more matter; the cavernous or spongy texture of the bone becomes conspicuous. 3. The CARNEOUS CARIES, or ulcer of the bones with hypersarcosis: this sort differs from the worm eaten caries only in the addition of spongy flesh growing in the cells of the bone; this spongy flesh often bleeds, if touched with the greatest caution. 4. The PHAGEDENIC CARIES with hypersarcosis: in this case the periosteum is thickened, the bone softened, and its surface is eroded, a yellow red spongy substance sprouts out; the difference betwixt this and the carneous caries is, that in the latter the spongy flesh grows out of the caverns, while their grey or brown coloured spongy bony sides still remain; but in the former, the bony fibres disappear wherever the spongy flesh comes, so that one can scarcely determine by the probe whether or no the bone is carious: upon scraping away the flesh, so destructive to the bone, its surface appears rough indeed, but not much eroded, nor greatly altered in its colour. 5. The SCROFULOUS CARIES is sometimes observed when an abscess is opened; the bone at the bottom of it appears white and smooth, without its periosteum or any connection to the neighbouring parts, except by its ligaments at the extremities; and this kind of caries most commonly happens in scrofulous habits. 6. The SEIRRHO-CANCEROUS CARIES: in one species of exostosis the tumefied bone is softer in one part than in the other, and is not composed of regular fibres, nor cavernous, but as if the ossifying juice had been thrown out irregularly, over which a cartilaginous or tendinous substance had spread; and from this a firm shining smooth flesh grows out, which, after the teguments are removed, sends forth a thin stinking acrid sanies. The patient complains often of throbbing pains in the part, and sometimes considerable hæmorrhages are made from imperceptible vessels on its surface. 7. The SPREADING CANCEROUS CARIES: in the spreading eating cancers the bones are wasted, as well as the soft parts, and the appearances are the same in both, unless that the bones do not consume quite so fast. 8. The SYPHILITIC CARIES affects chiefly the tibia, frontal bone, the ossa nasi and palati, and the sternum. 9. The ANEURISMATIC CARIES affects any bones in the neighbourhood of an aneurism.

In considering a caries of the bones, we should remember, that the bones have their vessels and circulating fluids, and the same general texture which the soft parts have; so that solidity, and a stronger cohesion of parts, are their only evident distinguishing characters.

Caries of spongy bones is cured with greater difficulty than of compact ones. Caries of the bones of the carpus and tarsus is, from their vicinity, easily communicated to the neighbouring ones. The disease, when it occurs in the deeper seated bones near the trunk, is seldom to be relieved or cured. It partakes also of the danger of its cause; since, as cancer and scrofula are incurable, little expectation can be enter-

tained of caries from either source. In young persons also it is more easily cured than in old.

Heister observes, that the cure of a caries depends on removing easily and speedily all the corrupted parts of the bone, and that in the gentlest cases this is done by *rectified spirit of wine* being applied by means of lint dipped in it; or *alcohol caryophyllatum*, made by mixing alcohol. ℥ iij. ol. caryoph. ℥ i. This applied upon lint to carious bones quickens the exfoliation. Vinegar used in the same manner has been thought to answer the purpose equally well. In more violent cases, a *solution of mercury in aqua fortis* is required, and in the most malignant the *actual cautery* will be necessary: but these hinder suppuration, and retard the operation intended. See EXFOLIATIO.

An exfoliation of the carious laminae of the bone sometimes takes place in two or three weeks, and in other instances the laminae are not removed in a year.

It is necessary to examine strictly all circumstances, and to discover, if possible, what cause, either general or topical, may have induced the disease, that endeavours may be used to remove it, if it still subsist: the *lues venerea*, *scrofula*, *scurvy*, *gangrene*, *abscess*, *wounds*, *contusions*, and many other diseases may be the cause.

When the bone is perceived to separate, if the pus which flows from under it is mild and in a due quantity, it will be the best application, and nothing is to be done but to remove the pieces of bone as often as they are perceived to be loose. If the quantity of pus is too small, ung. resinæ flavæ, or a similar digestive, is useful. If the opening in the integuments is so small that the matter detained is either absorbed into the circulation or forms sinous ulcers, the aperture must be enlarged by means of sponge tents, and kept open by dosils of lint. Indeed, if the exfoliation is likely to be tedious, in some cases it may be hastened by the use of a caustic or actual cautery, though in general the suppuration, which contributes to throw off the diseased part, is thereby retarded; or the rasp may be used: if instead of the actual cautery a potential one is preferred, the common caustic is the best.

When caries is accompanied by an acrid discharge, which consumes the surrounding parts, this fluid may be absorbed by dry powders, and pledgets dipped in tincture of aloes and myrrh; or, in more violent cases, in a solution of nitrat of silver. The disease is then reduced to a necrosis. The dried piece should afterwards be moved frequently, and the fungous flesh, which would prevent exfoliation, prevented from rising. Sometimes, however, the strongest caustics will not desiccate the bone. The fluid discharge dilutes and lessens their action, and the actual cautery becomes necessary.

In the WORM EATEN CARIES it is necessary to destroy all the affected part of the bone as soon as conveniently can be done, by rasping, chiseling, or trepanning, according as each instrument can be applied; after which, the method above described is to be pursued. When the ulcer is deep, honey, dissolved in vinegar and water, may be injected into it every day.

In the CARNEOUS CARIES, the fungous and corrupted parts are best destroyed by a caustic; though Gough, in his Cases and Remarks, vol. ii. p. 352, gives an instance of the inefficacy of caustics in this case, and of

the necessity of using the actual cautery, which he in general prefers.

The PHAGEDE'NIC CARIES may be reduced by one or two applications of the potential cautery to the most simple kind of caries; but sometimes great difficulties attend it.

In the SCROFULOUS CARIES, the teguments which cover the abscess formed on the bone must be destroyed with a caustic; the eschar cut through the middle to evacuate the matter; and to save the eschar as long as possible, mild applications only should be laid on the sore; then, to assist the discharge of the matter, it should be washed with water; but if fetid, with vinegar and water.

In general a mild treatment is to be preferred. In the slighter cases we must endeavour to excite and continue a degree of inflammation in the adjoining sound part of the diseased bone, so that it may be the means of separating the mortified part. This is done by making a number of small perforations all over the surface of the carious bone, to such a depth as to give the patient a very little pain, and no further: this operation may be renewed in different parts every third day, or thereabout; thus suppuration will take place, and a consequent separation of the carious part. But when the disease is extensive, and goes deeper than the second lamella of the bone, instead of little perforations made by the pin which fixes the trepan, it will be advisable to use the small head of a trepan. This instrument, applied at proper distances over the surface of the caries, and carried just so deep as to produce a little uneasiness, will occasion the necessary inflammation and suppuration. As soon as any of the parts loosen at the edges, their final separation may be always hastened by daily insinuating below them the end of a common spatula, so as to press their edges a very little upwards. After the use of those instruments, apply to the ulcer the same dressings as in cases of a simple ulcer; and to moderate the fetor of the caries, they may be covered with lint, moistened with a strong decoction of the cort. Peruv. and fol. juglandis. After the separation, the dressings are the same as in cases of simple ulcers in fleshy parts. If the caries penetrates very deep into the substance of a bone, so that a considerable portion is affected, or, as frequently happens, the disease extends even round the bone, the shortest method is to take out at once all the diseased parts, either with the head of a trepan frequently applied, or by means of a small spring saw. This may be performed on the skull, hands, feet, legs, or arms. See the article TIBIA for the process.

In the SCIRRHO-CANCEROUS CARIES, as in cancers of the glands, extirpation is the only remedy; but here also the disorder is apt to return in another part.

The SPREADING CANCEROUS CARIES seldom heals: it may be dressed with lint, or a cautery may be applied; but it generally breaks out again after a seeming cure.

In the SYPHILITIC CARIES, we must at first check the original disease. To the bones of the head, however, we cannot apply caustics, except to the mastoid process of the temporal bone. The other affected bones must be removed by the trepan. The other bones of the face, as the antrum maxillare from abscess

there, or the os unguis from fistula lachrymalis, when carious, readily exfoliate. If the causes are removed the parts heal without any particular management.

Parts of the sternum are from different causes carious; and these may be safely removed, since the pleura thickens and becomes cartilaginous. It may be also defended by a piece of leather or pasteboard. When it is thought dangerous to remove it, the bone may be perforated in a depending part to prevent the confinement of matter.

Some assert that sea water is more efficacious in caries of the bones than in glandular swellings.

A caries of the whole bone or bones, forming a limb, is sometimes productive of the necessity of amputation: particularly when the internal surface of such bones is affected as well as the external, through the whole extent, or near it. In such instances, if the whole bone is not removed by amputation, the patient will perish. It too often happens that in young subjects, with the best health, the whole habit will be so injured by the carious bone, and a hectic fever of the putrid kind, with all its horrid train of symptoms, will quickly destroy the patient.

CAR'IMA. (Indian.) See CASSADA.

CARIM-CURI'NI. (Indian.) *Justicia ecbolium* Lin. Sp. Pl. 20. An Indian shrub, the bark of which is used in a decoction against the gout; and a decoction of the leaves against a disury. Raii Hist.

CAR'INA. The keel of a boat or ship. In botany it is the inferior petal of a papilionaceous corolla; inclosing the stamens and pistil, usually shaped like a boat.

In zoology it is applied to the first rudiments of the spine of a chicken during its incubation.

CARIO'SSE. See ADY.

CA'RIMUM TE'RRÆ. LIME. See CALX.

CARIVI'LLANDI. See SARSAPARILLA.

CARLI'NA, or CAROLINA, (from *Carolus*, *Charles the Great*; because it was believed that it was shown to him by an angel; and that by the use of it his army was preserved from the plague). CARLINE THISTLE. The species used in medicine is the *Carlina acaulis* Lin. Sp. Pl. 1160. It is also called *cardo-patium*, *crocodilion*, *heracantha*, *ixia*, *chamæleon albus*, *acauclos magno flore albo*, *Carlina humilis*, the LOW CARLINE THISTLE.

The species with the flower, composed of a number of white petals set around a middle disk, is a native of the mountainous parts of Italy and Germany. The roots have a strong disagreeable smell, and weak, bitterish, subacid, aromatic taste. They are diaphoretic, hysteric, and anthelmintic; used in hysteria, tumours of the abdomen, and diseases of the skin. The dose from ʒi. to ʒi.

CARLI'NA ACAULIS GUMMIFERA. See CARDUS PINEA.

CARLO SANCTO, RADIX. ST. CHARLES'S ROOT.

It is found in Mechoacan, a province of America : its bark is easily separated from it, and hath an aromatic flavour, with a bitter acrid taste. The root itself consists of slender fibrils. The bark is sudorific, and strengthens the gums and stomach : the Spaniards call it *St. Charles*, and dedicate it to him on account of its great virtues.

CARMES, EAU DE. CARMELITE WATER, called also MAGISTERIAL WATER of BAUME'. It hath its name from being invented by the Carmelites at Paris.

Take of fresh baum, six ounces; fresh lemon peel, the yellow part, two ounces; nutmegs and coriander seeds, of each half an ounce; bruise them, and put them into rectified spirit of wine and pure water, of each a pint and a half: let them stand in a moderate heat for three days, then draw off two pints and a half in a vapour bath. Rectify the distilled liquor by a second distillation in a water bath, drawing off only two pints.

Mr. Beaumé observes, that all aromatic spirits ought to be prepared in the same manner; that in this rectification only the more volatile, subtile, aromatic parts, arise; a white, acrid, bitter liquor, loaded with the grosser oil, deprived of all the specific flavour of the ingredients, remains. He further observes, that aromatic spirituous waters have less odour when newly distilled than after they have been kept about six months; and he found that the good effects of age were produced in a short time by means of cold; and that, by plunging quart bottles of the liquor into a mixture of pounded ice and sea salt for six or eight hours, it proves as grateful as that which hath been kept many years. Simple waters also, after having been frozen, prove far more agreeable than they were before. Geoffroy takes notice of this melioration by frost. See Hist. Acad. 1713.

CARMINA, VERSES. So called because charms usually consisted of verses. Also INCHANTMENTS. See AMULETA.

CARMINA'NTIA, or CARMINATI'VA. CARMINATIVES. In general, by these words are meant such medicines as are used to expel wind from the alimentary canal. The ancients had much of mystery in their practice, and celebrated these medicines by singing verses when they administered them, as by their frequent speedy relief they seemed to act as by a charm; so from *carmen*, the Latin word for a *verse*, the word *carminative* is derived. Others derive it from *carmino*, to card wool, or cleanse it from foulness, or from *carmina*, charms. They were supposed to attenuate and discuss wind or vapours, and promote their discharge by perspiration. We have already had occasion to mention, that, in the process of digestion, much air is expelled, which is again combined with the alimentary mass, and afterwards separated by the different secretory organs. When this process is disturbed by accident, or not properly carried on in consequence of weakness, the air is not combined, but accumulates in the stomach, producing pain from the distention. But, though the accumulation of wind will alone create great inconvenience, and prevent its own escape, yet it seems seldom to amount to a disease, except the stomach be spasmodically contracted. When such spasms take place, wind, before unnoticed, creates uneasiness. Carminatives, therefore, at present, are confined to such medicines as, by their stimulating and antispasmodic

power, increase the action of the primæ viæ, take off spasmodic affections, and thus promote the expulsion of flatulencies.

Our own lighter aromatics, particularly peppermint, are highly useful; occasionally combined with ardent spirits. The fetid gums also, as the asafœtida and galbanum, are employed with great success; but, perhaps, the chief and most effectual carminative is opium.

CARNE'E COLUMNÆ. See COR.

CARNI'CULA, (from *carnis*, the genitive of *caro*, *flesh*). Fallopius uses this word instead of *caruncula*, to signify in particular the flesh which surrounds the gums.

CARNIFO'RMIS ABSCE'SSUS, (from *caro*, *flesh*, and *forma*, *likeness*). An abscess with a hardened orifice, and of a firm substance, or hard consistence, like a shell; not much elevated into a tumour, but broad and expanded, with membranes, fibres, and capillaries, usually interspersed. It generally rises where the muscles are inserted into the joints. Severinus.

CARNI'VOROUS, (from *caro*, *flesh*, and *voro*, to devour). FLESH DEVOURING. An appellation of the *assius lapis*. Animals also are thus called whose food is flesh.

CARNO'SA CU'TIS, (from *caro*, *flesh*). See PANICULUS CARNOSUS.

CARNO'SA MUSCULO'SA MEMBRA'NA. See FRONTALIS MUSCULUS.

CAR. STEPH. PRÆD. RUST. An abbreviation of Caroli Stephani Prædium Rust. Paris, 1629.

CA'RO, FLESH. By some it is said to mean, strictly speaking, DEAD FLESH, (from *careo*, to want, *quia caret animâ*, it wants life; but others think it more properly comes from the Hebrew term *karah*, food). In ANATOMY it is only the red part or belly of a muscle. In BOTANY it is the pulp of a fruit.

CA'RO ADNATA. Ad testem, et ad vasa. See SARCOCELE.

CA'RO MUSCULO'SA QUADRA'TA. See PALMARIS BREVIS.

CAR'ROBA, (from *charab*, Arabic). See SILIQUA DULCIS.

CARCE'NUM, (from *καρὰ*, the head, and *οἶνον*, *vinum*, so called because it affects the head). See MUSTUM.

CARO'LI. See CHANCER.

CAROLI'NA. See CARLINA.

CARO'PI. See ANOMUM VERUM.

CARO'RA, also *cynnina* and *cymia*. The name of a vessel that resembles an urinal.

CAR'ROS. See CARUM.

CA'ROS, CA'RUS, Καρῶς, or *carus*, synonymous with *sofor*, (from *καρὰ*, the head, which is chiefly affected). It is a slight degree of apoplexy, in which some broken incoherent answers are obtained from the patient. When called, he scarcely opens his eyes; yet, if stimulated, he hath feeling enough to manifest his uneasiness. The walnut tree is named from this disease, CARYON, q. v.

The *coma lethargus*, *coma vigil*, *coma somnolentum*, *cataphora*, differ only in degree; but apoplexy is the most violent of these diseases. Galen says, that if the *carus* oppresses respiration, as in those who snore in their sleep, it must be considered as apoplexy. See COMA.

Boerhaave observes, that a *carus* is a slight apoplexy from a hot cause, attended with a fever; and a lethargy is a slight apoplexy from a cold cause.

Hippocrates sometimes calls this disorder *aphonia*; Galen, in his *Method. Med. lib. xiii. catoche*; Cælius Aurelianus, *gravatio*; and Pliny, *gravedo*. Dr. Cullen arranges *carus* as synonymous with *apoplexia*. In a *carus* there are insensibility and sleepiness, with quiet respiration. It sometimes signifies a loss of sense and voluntary motion, respiration remaining uninjured.

The immediate cause of sleepy affections seems to be a defect of, or an impediment to the passage of the vital principle. The remote causes are, whatever diminishes the vis vitæ, or that can obstruct its influence; as tumours pressing on the brain, a turgescency of the vessels from obstructed menses and hæmorrhoids, a too free use of spirituous liquors, exposure to offensive vapours, blows on the head, &c.

Co'MA VI'GIL is known by a burning and extensive pain in the head, attended with a sense of ebullition in it. There is a strong inclination to sleep, but the patient either does not sleep, or awakes immediately with little or no relief: there is, however, no delirium. This disorder is always symptomatic, often attends acute fevers, and occasionally is the prelude of a phrensy, sometimes of an hemiplegia.

Co'MA SOMNOLE'NTUM, (from *somnus*, *sleep*). In this disorder the patient is languid, and his chief complaint is a constant drowsiness. He often falls asleep at meals, in conversation, and in the midst of business; and, when awaked, he soon sleeps again. Luxurious old men are most subject to it. It is a primary disorder, and unattended with fever, but often the first symptom of apoplexy. This and the former species equally arise from over distended vessels: but, in the coma vigil, the distention is only in a degree to produce irritation; in the second it is increased so as to occasion compression.

CA'RUS is a profound sleep, from which the patient is with great difficulty roused, though he seems sensible of pinching, or pricking him with pins, he either does not speak, or he immediately relapses into the same degree of sleep. This disorder is either idiopathic or symptomatic, and often attended with a fever. When symptomatic, it is said to be of three kinds; but is only the same disease in the different periods of that complaint, of which it is a symptom. The first happens early in acute fevers; and, if convulsions and hiccough come on, is soon fatal. The second appears after acute fevers; and, when the patient is exceedingly weak, the sleep will continue for several days: if it happens in acute fevers on critical days, with a sweat, and the countenance not changed, it is salutary. The third happens a day or two before death, when, the patient's strength being exhausted, he lies deprived of sense and motion, as it were in a profound sleep, and under it expires. In this state the countenance sinks.

LETHA'RGUS, (from *λεθη*, *forgetfulness*, and *αργος*, *slow*), also called *vetérnus*, a LETHARGY; is a heavy perpetual sleep, with scarcely any intervals of waking. When awakened, the patient answers; but, ignorant or forgetful of what he said, he immediately sinks into the same state of sleep: indeed it is attended with such a stupidity and forgetfulness, that whatever the patient

begins to do, he forgets to proceed in it, and falls asleep. It is attended with a fever, which is chiefly discovered by the frequency of the pulse; and does not invade so suddenly as an apoplexy, nor kill so soon. By some it is considered as generally symptomatic; it is often the attendant of fevers, and usually a very dangerous symptom. In this disease there seems to be an utter loss of all the rational powers, and inaptitude to motion, whence some have named it *desidia obliuosa*. Dr. Cullen thinks it a symptomatic apoplexy.

Bonetus, in his *Sepulchretum Anatomicum*, observes, that in those who died of sleepy disorders, a copious serum was found diffused through the substance of the brain, chiefly in the cortical part: in some he found the ventricles replete with serum, and the cortical part unaffected; and these, he says, were never troubled with lethargic diseases. But he observes, that the more this watery fluid penetrated into the medullary part of the brain, the more obstinate was the sleepiness during the life of the patient. In some who died of drowsiness, he found abscesses, tumours, and scirrhus of the brain; but these were only on its anterior and cortical region. In some he found the vessels of the pia mater very much distended with blood.

The CoMA VI'GIL should be distinguished from the pervigilium; each of these disorders from one another; and all from apoplexy, hysteric fits, syncope, and hydrocephalus.

In whatever view we consider this disease, it will appear to be chiefly a less violent apoplexy, varying in its degrees rather than its nature or causes. To distinguish the different species from each other, or from apoplexy, is therefore of little practical importance; but these diseases often so nearly resemble a fit of hysteria, syncope, or the advanced state of hydrocephalus, that some little attention will be required.

The previous state of the patient will point out the hysteric paroxysm. In this last disease, however, the pulse assumes every variety both in strength and quickness; but the constitutions which each affects are very different, and the previous indisposition of the stomach, the attack commencing with flatulence, the neck swelling, the absence of either a fulness or redness in the face, which occurs when *carus* proceeds from over distended vessels, or a peculiar sinking in the features, when from narcotic vapours, sufficiently distinguish the complaint. In an hysteric fit the countenance is little altered.

Nearly the same symptoms distinguish *carus* from syncope; to which we may add, that the latter, if common, cannot easily be mistaken; if a single occurrence, the cause will point out its nature. The distinction of hydrocephalus is not so easy. In the early state of irritation the disease does not resemble *carus*: in its latter period, the strabismus, and the slow pulse, sufficiently point out water in the head. Yet there are cases where neither occurs, and where even the pupil dilates and contracts. The history of the complaint must then come in aid, and little difficulty will arise. If we suppose an error, no great harm can result; and, in doubtful cases, the practitioner should act as if it were *carus*.

A more important consideration is, whether *carus* be idiopathic or symptomatic. It is often a symptom only of disordered stomach; and, as we have remarked, it

is a symptom of fevers. In the whole course of medical practice, we know no case of greater difficulty than the distinction of complaints affecting the head and the stomach with respect to the primary affection. After a long practice, we are often deceived; nor can any precise limits be drawn. Every case is peculiar to itself; and the practitioner can only be assisted by an attentive examination of the origin and progress of the complaint, the effects of remedies, and the various *jvantia* and *lædientia* of the dietetic kind. Even the apparently pathognomic symptom of a noise in the ears is, in elderly persons, more frequently the effect of weakness than of over distended vessels.

When a complaint of this kind occurs in fevers, it is, as we have hinted, a dangerous symptom; and it then seldom arises from over distended vessels, but from weakness. In slow fevers, however, which approach insidiously, this symptom unexpectedly comes on; and all the evacuants, with every method of rousing the patient, are employed, till the powers of life, at once exhausted, yield. We may repeat the metaphor formerly employed, which the young eager practitioner should constantly keep in mind: a gentle gale may animate the flame which a violent wind will extinguish.

An attack of apparent carus, or even of its increased degree approaching apoplexy, often happens in young and strong persons from long exposure to the sun. In such cases we have seen leeches, blisters, and the whole train of evacuants, employed with little success. The disease is in fact a less degree of the *coup de soleil*; and moderately warm stimulants, with tonics, and, above all, rest, with patience, are only adequate to the relief. Its immediate cause is obscure; but, whatever it may be, we are not yet in a condition to explain it. Various preliminary facts must be previously stated.

Narcotic poisons and effluvia are more common causes of carus than of apoplexy. These also require a stimulating plan. Cold water dashed on the surface, oxygenous gas injected into the lungs, volatile spirits applied to the nose, and stimulating cataplasms to the feet, are all necessary. In other respects the treatment does not essentially differ from that of apoplexy.

CAROTĀ. See DAUCUS.

CAROTIDÆ ARTERIÆ. The CAROTID ARTERIES; from *καρὰ*, the head, or *καρπος*, sleep; since, when the current of blood is diminished through these vessels, stupor follows.

From the fore part of the curvature of the aorta, just before the trachea, the right subclavian and the carotid mostly arise in one common trunk, which runs upwards a little way, and then divides. The left carotid rises singly, and runs upwards on the side of the trachea. Both these carotids run up as high as the side of the larynx, even to the upper part of the thyroid cartilage, before they give off one branch, and there they divide into the external and internal: the latter goes to the inside of the cranium; the former, which is the largest, gives branches to all the external parts of the head.

The external carotid is anterior, the internal is posterior; the external situated more inward and nearer the larynx. It is the smallest, runs insensibly outward between the external angle of the lower jaw and the parotid gland, which it supplies as it passes; afterwards it ascends on the fore side of the ear, and ends in the

temples. It sends off the gutturalis superior, sublingualis, maxillaria inferior, maxillaria externa, &c. The internal carotid leaving the general trunk is, at first, a little incurvated. It is situated a little more backward than the external, and generally runs up, without any ramification, as high as the lower orifice of the great canal of the apophysis petrosa of the os temporis: it enters this orifice, and the cranium, through an irregular aperture in the sphenoidal bone; and, except one branch, which goes to the eye, it is wholly spent upon the brain. See Winslow's Anatomy.

CA'RPASUS, (so named *παρα το καρπον ποιησαι*, because it makes the person who eats it appear as if he was asleep). An herb, the juice of which was formerly called *ophocarhason*, *ophocarpathon*, or *ophocalhason*: according to Galen, it resembles myrrh; but is esteemed highly poisonous. It is not certainly known what it is; yet Bruce thought he had found it in a species of acacia, called *sassa*, which is not poisonous. It differs little from the mimosa Nilotica.

CA'RPATA. See CATAPUTIA MINOR.

CARPA'THICUM. From the fresh cones of the trees which yield the common turpentine is distilled a fine essential oil, said to be *carpathicum*, or *Germánia Æleum*.

CARPERITA'RIA. See BARBAREA.

CARPE'SIUM, (from *καρπος*, fruit). This is an aromatic vegetable; it is often mentioned by the ancients, and is probably the *carpesium cernuum* Lin. Sp. Pl. 1203.

CARPHOS. See FÆNUM GRÆCUM.

CA'RPUS, (from *καρφη*, a straw). In Hippocrates it signifies a straw, a mote, or any small substance. It also signifies a small pustule, for the cure of which Ætius, Tetrab. i. recommends rubbing them with dried seeds of the herb mercury.

CA'RPĪA, (from *καρπο*, to pluck off, as lint is from linen cloth). See CARBASUS.

CA'RPĪO, (from *καρπο*, to seize; so called because of its voraciousness). Called also *carpia*, *cyprinus*. The CARP. Fish of this kind fed in rivers are better than those fed in ponds; and of these the largest and fullest are the best. They live on herbs, slime, and the smaller fishes. They are nutritive, but not highly flavoured, and the fat is indigestible. The head is the finest part of the fish; and of the head, the tongue is the most delicate.

CARPOBA'LSAMUM, from *καρπος*, fruit, and *βελανιδιον*, balsam). It is the fruit of the tree that yields the BALM OF GILEAD. See BALSAMUM.

CARPOLO'GIA, (from *καρπο*, to pluck, or pull gently). A delirious motion of the hands; as when a patient seems to be gathering something from off the bed clothes, which yet is imperfectly performed, because of the trembling which affects them. It is usually a fatal symptom in fevers.

CA'RPOS. (Greek.) See FRUCTUS and SEMEN.

CARPUS. *Καρπῶς*, a Greek primitive, a WRIST, called by the ancients *brachiale*. It consists of eight bones; viz. the *os scaphoides*, *lunare*, *cuneiforme*, *pisiforme*, *trapezium*, *trapezoides* *magnum*, and *unciforme*. The first three make an oblong head, by which they are articulated to the lower extremity of the bones of the fore arm by arthrodia. The articulation of these three bones, with the bones of the inferior row, is such

as allows of motion, especially backward and forward, to which the arthrodia of the os magnum with the scaphoides and lunare greatly contribute. The trapezium on the one side, the pisiforme and cuneiforme on the other, being raised above the rest of the bones of the carpus, make a sort of arch for the secure passage of the flexors of the fingers; and the transverse ligament being extended from one side of the arch to the other, binds them down to their proper place. Lyserus gave the eight bones of the wrist their respective names. The four bones of the second row are all in a line, the first being articulated with the thumb, and the rest with the metacarpus. These bones are very spongy. See Winslow's Anatomy.

**CARTHAMUS**, (from the Arabic term *kartham*). **BASTARD SAFFRON**. Called also *cnicus*; *crocus Saracenicus*; *carthamum officinarum*; *carduus sativus*, **SAFFRON FLOWER**; *carthamus tinctorius* Lin. Sp. Pl. 1162. Nat. order *cynarocephali* of Jussieu. It agrees with the thistle in most of its characters, but its seeds are destitute of down. The leaves are oval and pointed: on the tops grow scaly heads, with saffron coloured fistulose flowers; these are followed by smooth white seeds, of an oblong roundish shape, yet with four sensible corners remarkably heavy, so as to sink in water.

This plant is annual, a native of Egypt, and cultivated in other places on account of its flowers, which are used in dyeing. It does not arrive at much perfection in England.

The seeds have an unctuous sweetish taste, which on chewing are acrid and disagreeable. With water they form an emulsion by trituration; and to spirit they give out a little nauseous, acrid matter. They are cathartic in doses of one or two drachms; supposed also to be diuretic and expectorant, particularly useful in humoral asthma, and similar complaints. The flowers are difficultly distinguished by the eye from true saffron, when they are well prepared; but they have neither its smell nor taste. They give to spirit of wine a deep saffron tincture, and to water a paler yellow. After the yellow matter is extracted by water, the flowers appear of a red colour, and communicate to spirit of wine a deep red.

Some have the art of preparing the seeds of melons and of cucumbers, so as to resemble the exoriated seeds of bastard saffron; but the genuine seeds are not so white as the artificial.

The **CARTHAMUS LANATUS** is considered in France as a febrifuge and sudorific. (See **CARDUS** and **ATRACTYLIS**). The *carthamus gummiferus* of naturalists is the *atractylis gummifera* of Linnæus. Its juice is milky, and it concretes in the form of a gum.

**CARTHUSIA'NUS PU'LVIS**, (from the *Carthusian monks*, who were the inventors). See **ANTIMONIUM**.

**CARTILAGINO'SUM**, (from *cartilago*, a cartilage). See **PATELLA**.

**CARTILAGO**, (quasi *cartilago*, from *carnis*, the genitive of *caro*, *flesh*). A substance between muscular flesh and bone. A **CARTILAGE** or **GRISTLE**, called also *chondros*. Dr. Hunter defines it to be a smooth, solid, diaphanous, elastic, insensible, inorganic substance. He observes, that in the fresh subject it appears uniform, and without any visible fibres; when cut in any direction, its surface appears smooth, like wax or

glue. On a cartilage there is no periosteum; but its place is supplied by a similar membrane, styled the perichondrium. Cartilages are the least affected by pressure of all animal substances, while the body is living: their substance is firm and dense, and their texture so fine, that, when cut, they appear only like a very stiff jelly.

Cartilages are distinguished into three kinds:

First, such as supply the place of a bone in an adult, as the *trachea*; secondly, such as supply the place of bones in young subjects, as *epiphyses*; and, thirdly, such as are *common to the fetus and adult*, and are expanded on the extremities of articulating joints.

Bones, it is supposed, are only cartilages, into which the calcareous phosphat has been secreted; and, when nitric acid has dissolved the latter, the shape of the bone is thought to be preserved by its cartilaginous substance. This, however, is not correct, as we have already shown; and the matter which remains after solution is rather membranous, with a portion of gelatine attached to the membranes.

Cartilages differ greatly from bone. They are insoluble in cold water; but they yield to the water at a boiling heat, forming a jelly, and at last a glue. Yet, even to cold water, they impart a small proportion of gelatine, which becomes sour. The jelly procured by boiling water becomes first sour, and then putrid, but not in a high degree; and the animal matter procured by distillation is much less than from the same bulk of muscular, or almost any other animal, substance.

The articulating cartilages cannot be injected to their middle solid part, though the vessels of its membrane are easily filled. The cartilages are supposed to be supplied with nerves, but they are too minute to be visibly demonstrated.

The uses of the articulating cartilages are, first, to prevent abrasion, as without them the continual attrition of the bones against each other's surface must have destroyed them; secondly, by their elasticity, they break the force of collision; thirdly, they serve as indolent bodies, to admit of motion and friction without pain. They sometimes answer the purpose of ligaments, occasionally of bones.

A disease never affects the cartilages primarily. They are incapable of exfoliation; but when diseased from some preceding disorder of the bone, the whole is generally affected, and the cohesion between the cartilage and the bone in the joint being less than between the parts of the cartilage itself, causes it to separate from the bone. If a part of the cartilage is destroyed, it is never restored.

**CA'RUI** and **CA'RUM**, also called *carvi*, *cuminum pratense*, *caros*; *CARAWAIES*. It is the *carum carvi* Lin. Sp. Pl. 378. Nat. order *umbellifera*.

It is a native of the northern climes; cultivated in gardens with us; but by chance found wild, and is a biennial plant. Its roots and leaves are esculent.

The seeds are warm and carminative; have an aromatic smell, a warm penetrating taste, and are given in powder from ʒj. to ʒj. They dispel wind, are cordial, stomachic, and assist the digestive powers; recommended in dyspepsia, flatulencies, and some hysterical and hypochondriacal affections. Carui seeds excite the discharge of saliva, and are said to be emmenagogue. They are used in palsies: the oil is supposed

to be advantageous in tooth ach. In the complaints of children, they are boiled with advantage among the laxative ingredients of clysters. Custom even retains them in those of adults. They differ only from anise-seeds in the peculiarity of their odour.

An extract made from a tincture, with rectified spirit, retains all the virtue of the seeds. After infusion in water, spirits extract a strong tincture; watery infusions are strongest to the smell, and spirituous ones to the taste.

When distilled in water, all their aroma rises. They afford an essential oil, which is a warm carminative, and given in doses from one to five drops: and there is also a spirit drawn from the seeds. SPIRITUS CARUI is made by adding half a pound of bruised carui seeds to a gallon of proof spirit, with a little water to avoid empyreuma, and distilling off a gallon. It has been used as a stomachic; but, by such medicines, the pernicious habit of drinking drams is often incautiously introduced.

CARU'NCULA. A CARUNCLE. This word is a diminutive from *caro*, *flesh*. A caruncle is a small piece of flesh, or an excrescence that hath the appearance of flesh. Thus there are the *carunculæ lachrymales* in the corners of the eyes; the *carunculæ myrtiformes*, which are at the entrance into the vagina, formed, or rather discovered, by the rupture of the hymen (see HYMEN); the *papillares carunculæ* of the kidneys; and a caruncle of the urethra at the orifice, which opens from the vesiculæ seminales; besides many others, all which are the productions of nature. The uvula is sometimes called *caruncula*.

Morbid excrescences of flesh are called *caruncles*, as well as small portions of a fleshy substance sometimes discharged in a dysentery by stool, or in diseases of the urinary passages by urine.

Excrescences in the urethra arise from its ulcerated or excoriated sides, by sharp corroding matter lodging there: these are often mistaken for the stone, or occasion nephritic symptoms, but are owing to a stricture in the urethra. In this case, when the urine is discharged, it passes from the urethra divided into two or more streams, sometimes only with pain, and in drops; but the only certain proof is, passing a probe or bougie up the urethra, until the obstruction is met with; and if any is found on this side the valve, at the entrance of the bladder, there is reason to suspect caruncles to be the cause. They are cured by the bougie. Bell's Surgery, vol. ii. p. 188.

CARU'NCULA LACHRYMALIS, is situated between the internal angle of the eye lids and the ball of the eye; it is a small reddish oblong substance, and hath the appearance of being fleshy, though it is thought to be glandular. The ancients call it *glandula lachrymalis*, also *glandula innominata*. It serves to prevent the internal edges of the lids at that part from coming into contact with one another; and the orifices of the lachrymal points are kept open, so that the tears pass freely through them into the sac.

CARU'NCULÆ MYRTIFORMES, (from *myrtus*, a myrtle, and *forma*, a likeness, because they are like the myrtle berry). They are several small knots or protuberances at the entrance of the vagina; they are the remains of the ruptured hymen, and, when large, have been taken for cancers.

CARUNCULO'SA ISCHURIA. A suppression of urine, from caruncles in the urethra. See ISCHURIA, 4th species.

CA'RVA. See CASSIA LIGNEA.

CA'RYA, a walnut, (from *καρυ*, the head, because it is round like the head). See JUGLANS.

CA'RYCE, or CARYCIA. Galen says it is a costly food prepared by the Lydians. Varinus supposes it to be thus called, because it was black like the boiled walnuts; from *καρυον*, the walnut.

CARYE'DON, (from *καρυα*, a nut). See ALPHITIDON.

CA'RYL. See CORALLODENDRON.

CARYO'CES. A Portuguese name for the fruit of the Guinea palm tree. See also ADY.

CARYOCOSTI'NUM ELECT. (from *καρυον*, *caryophyllus*, and *κοστίνας*, composed of *costus*, so named from its ingredients). See SCAMMONIUM.

CA'RYON. A NUT. (From *καρυ*, the head, from its rotundity.) This word is applied to all such fruit as inclose somewhat eatable within a hard shell. Plutarch says that the ancients called the walnut *caryon*, because it induces a heaviness and stupidity of spirits; probably derived *καρυ το καρον*, from its causing sleep. See CAROS.

CA'RYON BASI'LICON. See JUGLANS.

CA'RYON HERACLEO'TICON. A small nut, as a hazle nut or filbert; from Heraclea, in Pontus, whence it was brought into Greece.

CA'RYON LE'PTON. A small nut, as filberts, or hazle nuts; from *λεπτος*, small.

CARYOPHYLLA'TA: also *herba Benedicta*, *caryoph. vulgaris*, *garyophylla*, *janamunda*, *avens*, HERB BENNET. It is called *caryophyllata*, from *caryophyllus*, because its smell resembles that of clove July flowers. *Geum urbanum* Lin. Sp. Pl. 716. Nat. order *rosaceæ*.

It is perennial, grows wild in woods and hedges, and is found in flower the greatest part of the summer.

The root is gently styptic, corroborant, and stomachic; hath a moderately austere aromatic taste, a pleasant smell, especially in the spring, and when produced on dry warm soils. It has been said to be astringent, vulnerary, and tonic; to cure intermittents where bark has failed. Indeed, it is strongly astringent with some aroma, when recently raised in the spring, and from a dry soil. There is great reason to doubt its efficacy in intermittents, as the experiments of the Swedish physicians contradict those of the Danes and the Germans, who are the great advocates for this medicine. It gives its aroma chiefly to spirits, and its astringent matter to water or to spirit. In distillation with water it affords a small quantity of an agreeable concrete oily matter; and the remaining decoction, if inspissated by evaporation, is moderately astringent. Lewis's Mat. Med. Cullen's Mat. Med.

CARYOPHY'LLATUM A'LCOHOL. See CARRIES.

CARYOPHY'LLI AROMA'TICI, (from *καρυον*, a nut, *φυλλον*, a leaf, and *αρωμα*, odour). The AROMATIC CLOVES; called also *garyophyllus*, *hinka*, and *clous*. It is the unripe fruit, or rather the cups of the unopened flowers, of a tree which grows in the Molucca Islands, of the natural order of the myrtles. In shape, it resembles a short thick square nail, of a rusty colour, inclining to black: in the middle of each clove are found

a stylus or stamina, with their apices; at the larger end shoot out from the four angles, four little points, like a star, in the middle of which is a round ball of a lighter colour than the rest, composed of four small scales or leaves, which seem to be the unexpanded petala of the flower. The tree is the *caryophyllus aromaticus* Lin. Sp. Pl. 735. It, indeed, seems evidently to belong to the class *icosandria*; and modern botanists are said by Dr. Woodville, though we know not on what authority, to refer it to the genus *eugenia*. The clove tree is one of those whose flower is produced above the rudiments of the fruit: the ripe fruit, sometimes brought to England under the name of *anthophyllum*, or *antophyllum*, marked on the top with the remains of the flower, is about the size and shape of an olive, and contains, under a thin blackish shell, one or two hard kernels of the same colour, which hath a deep longitudinal seam on the side, composed each of two sinuous lobes; but this fruit is less aromatic than the immature flower. The cloves are said to be cured by exposing them to smoke, and afterwards drying them in the sun.

The largest, heaviest, most brittle, and darkest coloured, are the best, and those which feel oily when pressed. Another mark of their goodness is, when, on piercing them with a needle, a little liquid matter, like oil, oozes out. Those that are of a light brown colour have had their oil extracted.

Cloves have a strong but agreeable smell, a bitterish hot pungent taste; are one of the hottest, and most pungent and acrid, of the aromatic class; and have all the virtues ascribed to aromatics in general. When good, they have these qualities in a great degree, and almost burn the throat when swallowed. They are remarkably disposed to imbibe humidity; and, when robbed of their active parts, and afterwards mixed with fresh cloves, they regain from them a considerable share both of taste and smell. The Dutch extract the oil from them, and then mix them with others, from which it hath not been separated; but their dryness, less pungent odour, and pale colour, discover the fraud. The Dutch also preserve the fruit with sugar, which they eat in their voyage, to stimulate the stomach and prevent scurvy.

Rectified spirit of wine takes up all the virtue of cloves: an extract from this spirituous tincture amounts to nearly one-third of the cloves used in preparing it, and retains nearly their whole virtue. Infused in water, they give out to it more of their smell than to spirit, but not so much of their taste.

Distilled with water, they give over, very slowly, about one-sixth of their weight of essential oil, at first yellow, and afterwards a reddish brown; but if the fire is very moderate, its colour is pale: it sinks in water, is mild, and not very pungent; but the only way to have it genuine is to distil it ourselves. The Dutch oil is very acrid, and contains near half its weight of an insipid expressed oil. It is probable, that, from an admixture of the resinous part of cloves, this sophisticated oil receives both its acrimony and high colour; or, as fresh cloves are said to yield a high coloured fragrant thick oil upon expression, it may be, that the common oil of cloves, brought from the spice islands, is no other than this oil diluted with an insipid one. In Holland, the oil is distilled by holding the cloves in a moistened cloth over the funes of hot water. Heat is applied over

them; and the oil, dropping through the water, sinks to the bottom.

If the oil of cloves is adulterated with an insipid expressed oil, it is discovered by dropping a little into alcohol; and, on shaking them, the genuine oil mixes with the spirit, and the insipid oil, separating, is discovered.

Cloves are considered to act as powerful stimulants to the muscular fibres; and, in some cases of atonic gout and paralysis, may supersede most others of the aromatic class. In stomach and chlorotic complaints, they are often of considerable service. Though cloves powerfully excite the vital powers, they produce no serous discharges, and are accused of inducing constipation. In humoral asthmas they are said to be useful, and the oil rapidly cures the tooth ach. Its use as a condiment is well known. Both the spice and oil are used as correctors of some of our officinal compositions. The Dutch join it with bark and cream of tartar, in obstinate agues. Twenty cloves are added in powder to half an ounce of each of the other, and 3 ss. is given every third or fourth hour.

In dyspepsia, also against flatulence, and as a vehicle to other medicines, 3 ij. of cloves are infused in half a pint of boiling water. The dose, one ounce and an half, or two ounces.

The oil of cloves is made into an agreeable draught by mixing it with a proper quantity of gum arabic, and then with water. See Neumann's Chem. Works. Lewis's Mat. Med. Cullen's Mat. Med.

CARYOPHYLLI SUA'VIS ODO'RIS, &c. See CANELLA ALBA.

CARYOPHYLLOIDES CORTEX CARYOPHYLLON PLI'NII, (from *καρυοφυλλον*, *caryophyllum*, and *ειδος*, *likeness*, from their resemblance to the July flower). See CASSIA CARYOPHYLLATA.

CARYOPHYLLUS RU'BER, from *καρυον*, a nut, and *φυλλον*, a leaf; so called because it smells like the leaves of the Indian nut or clove tree). Hence it is a name applied to many plants of the pink and July flower kind. GILLYFLOWER; also called *tunica*, *vetonica*, *betonica coronaria*, *caryophyllum hortensis*, CLOVE JULY FLOWER; *dianthus caryophyllum* Lin. Sp. Pl. 587.

It is well known in our gardens, is perennial, and said to be a native of Italy. There are many varieties; but those employed for medicinal use are of a deep crimson colour, and an agreeable aromatic smell, somewhat resembling that of the spice; and this odour is not very soon dissipated.

These flowers are esteemed moderately cardiac, diuretic, and sudorific; but they are chiefly used in the form of a syrup, for the beauty of their colour.

The London college directs the following syrup from these flowers.

Take of fresh clove July flowers, with their heels cut off, two pounds; of boiling distilled water, six pints: macerate the flowers in the water for twelve hours in a glass vessel; and in the liquid, strained, dissolve as much double refined sugar as is required to make a syrup. It should be observed, that as the beauty of the colour is a principal quality of this syrup, no pressure of the flowers is to be admitted.

In St. Thomas's hospital a syrup is made from the aromatic clove, coloured with cochineal. See Lewis's Mat. Med.

**CARYOPHYLLUS AROMATICUS AMERICANUS.** See *PIPER JAMAICENSIS*.

**CARYOPHYLLUS HORTENSIS.** See *CARYOPHYLLUS RUBER*.

**CARYOPHYLLUS INDICUS.** See *ANTHELMIA*.

**CARYOPHYLLUS VULGARIS.** See *CARYOPHYLLATA*.

**CARYOTI,** (from *καρυον*, a nut). See *DACTYLUS PALMULA*.

**CAS GA'NGYTHREB.** See *VERBENA*.

**CASAMUM.** See *ARTHANITA*.

**CASCARILLA.** *CASCARILLA.* The Spaniards apply this word to the Peruvian bark, as we apply the word *bark* to distinguish the same material. It is a diminutive of *cascara*, the Spanish word for bark or shell; but is applied by us to a peculiar bark, very different from the Peruvian. See *THURIS CORTEX*.

**CASCHU.** See *TERRA JAPONICA*.

**CASEUS,** (from the Arabic term *casah*, milk). **CHEESE.** When old, it is called *palætyrus*. Aristæus, a pupil of Chiron, is said to have first discovered the art of making it. The ancients were well acquainted with the methods of coagulating milk; and for this purpose they boiled it, mixed it with vinegar, infused the branches of the fig tree in it, or added salt with sour milk.

The curd of milk is more or less dense, according as the whey is more or less perfectly separated from it. Its cohesion is never considerable; but the chief art of making cheese consists in separating as perfectly as possible the whey, for a very small proportion of moisture accelerates fermentation and putrefaction.

Curd or cheese is an albuminous substance, not unlike the white of an egg, or the coagulum of the blood. It dissolves in alkalis, but most perfectly in the caustic mineral alkali; and from its solution a volatile alkaline smell arises. The vitriolic and nitrous acids dissolve it; the marine acid less readily. In hot water it hardens; and cold has no effect on it. If the cheese is good, it melts easily: if poor, it becomes crisp and horny. By distillation, the water which first arises is nearly tasteless, but soon putrefies. In a greater heat the cheese blisters, and yields hydrogenous and carbonated gas, with some ammonia, and a heavy stinking oil. Its ashes contain phosphat of lime and calcareous earth. The curd of goat and cow's milk is solid and elastic; that of the ass and mare less solid; that of the sheep and women almost or entirely fluid. It is a common opinion, that old cheese digests every thing, yet is left undigested itself; but this is without a proper foundation. New cheese digests with difficulty, and when old is acrid and hot. Cheese made from the milk of sheep digests sooner than that from cows, but it is less nourishing; that from the milk of goats sooner than either, but is the least nourishing. In general, it is a kind of food fit only for the laborious, or those whose organs of digestion are strong. See *Galen de Alim. Facult.*

Dr. Cullen, in his *Materia Medica*, vol. i. gives a very minute account of cheese, and tells us "the cascous or coagulable part of milk contains certainly a great, if not the greatest part of the nourishment which milk affords, and is in itself the more nourishing the more it is united with the oily parts. When the coagulum has the whey taken from it, it becomes a more nutritious substance than the milk it was taken

from, but will probably be of more difficult digestion. Cheese in its dried state, when made from milk previously deprived of its cream, may be still nutritious, though of difficult digestion; but made of entire milk must be more nourishing, and of easier digestion; and made of entire milk, with a portion of cream taken from other milk added to it, will be still more nourishing, but hardly of less easy digestion, as the oil every where interposed between the parts of the gluten must render its adhesion less firm; and if cheese is made of cream alone, that will be certainly the most nutritious, and of the easiest digestion."

But cheese is not only made of cows' milk alone, but also of the milk of ewes and goats, and often of a portion of the two latter added to cows' milk. In all these cases, as the milk of ewes and cows contains a larger portion of the oily and caseous parts, so in proportion as these are employed the cheese becomes more nutritious, but at the same time often occasions inconvenience from its richness.

As cheese is employed not only when recent and fresh, but also under various degrees of corruption, so it acquires new qualities; and, according to the degree of corruption, it becomes more acrid and stimulant, partly by the acrimony thus acquired, and partly by the great number of insects that are very constantly generated in that state. It can then hardly be taken in such a quantity as to be considered as alimentary; and its effects as a condiment influencing the digestion of other food are difficult to explain, though they are commonly admitted. When toasted, it is certainly not easily digested by weak stomachs; as a portion of the oil is separated, and the coagulum rendered horny.

In general, cheese, as an aliment, is, as we have remarked, adapted to the healthy, the strong, and laborious. The coagulum always contains a sufficient degree of moisture to approach the putrid state, which is prevented from advancing rapidly, by the close compression it experiences. Yet, as a medicinal dietetic, it is often useful, even in debilitated stomachs. In those where acid abounds, good cheese is particularly serviceable; and in cases of flatulence it often relieves. It has been recommended as a diet in leucorrhœa; and we can perceive some connection between this complaint and an acid stomach, since absorbents have been recommended for its relief: as a condiment it is well known, and it has been properly said, that cheese digests every thing but itself; in other words, though undigestible, yet by its stimulus, or its antacid power, it contributes to the digestion of the various heterogeneous substances of a modern luxurious dinner, since a redundant acid is its most frequent consequence. It may be of use to know, that soft cheese relieves that unpleasant sensation often the consequence of an acid, which we express by the teeth being an-edge.

With respect to its component parts, cheese chiefly differs from the excess or defect of its oily part. The opposite examples are the cream cheeses of Bath, and the scald-milk cheese of the West. In the former, cream is added, and it is of course in a larger proportion than from the milk which nature offers. The consequence is, that compression is inadmissible; the acid fermentation soon comes on, increased fluidity is the consequence, and from that state it rapidly hastens to

putrefaction. The Bath cheese is nutritious, and we think easy of digestion. The Stilton cheese is not very different; and the Cheshire, the Gloucestershire, and the Bridgewater, follow in the order. Each is more oily and nutritious than its successor: each in the inverse order is more stimulating and indigestible, and still more so the farther the putrefactive process is advanced.

On the opposite side, the scald-milk cheese contains the curd almost wholly without the oil, which is artificially separated by heating the milk to a degree just below the boiling point. It is hard and indigestible; but we may add, that this only is the cheese proper for cements. From its dryness, it does not readily putrefy; though when putrid it is scarcely more indigestible than in its most perfect state.

The Roquefort cheese is soft, mild, and pleasant. The peculiar excellence of this cheese, from M. Chaptal's description, consists in checking the fermentation when it has reached a given point; for if neglected, it contracts a disagreeably sour taste. The milk of goats and sheep are only employed. The Swiss cheese derives its excellence from a similar management. It is cellular; and the cavities are filled with whey, which is in its passage from the acid to the putrid state. The cheese is also rich, and the peculiar poignancy of this whey renders it such a favourite with the epicure. The smell when toasted is so much heightened as to be generally unpleasing, except to the sensualist.—But we cannot enlarge this disquisition: these details belong rather to the economical science than to medicine. See LAC.

CA'SHOW. See TERRA JAPONICA.

CA'SIA, i. e. *Cassia*, (from the Arabic term *katsia*, and this from *katsa*, to tear off). CASSIA; so called from the act of stripping the bark from the tree.

CASMINA'RIS, CA'SMUNAR. See CASSUMMUNAR.

C. B. An abbreviation for Caspar Bauhine.

C. B. PIN. Caspar Bauhine's Pinax.

C. B. MATTH. Casp. Bau. in Matthiolum.

C. B. PROD. Casp. Bauh. Prodromus Theatri botanici.

CA'SSA, (from the Arabic term *katsa*). See THORAX.

CA'SSADA. (Indian). Called also *cacavi*, *cassave*, *tain de Madagascar*, *ricinos minor*, *maniot*, *yucca*, *maniiiba*, *aipi*, *aipima coxera*, *aipipoca*, *janipha*, *jatropha manihot* Lin. Sp. Pl. 1429. Nat. order *tithymeloides* of Jussieu, nearly related to the *crotons*. This plant grows in the warmer parts of the western world. Its root, which is only used, is called *yucca*; by the Mexicans *quanticamotli*; and when prepared into a flour, *cassavi*. Names for the preparations of the root, in order to make it into bread, are various. See MANDIBA.

This plant, which is a native, or at least a denizen, of three quarters of the world, is one of the most advantageous gifts of Providence to mankind. It grows in a dry, and in many respects an useless, soil; it is neither injured by seasons nor insects, and the roots of different varieties are fit for use at every period. It is nutritious, and, to those accustomed to the diet, pleasant, though to the European it is insipid. The plant is poisonous; but the poison consists in a volatile oil, which is easily separated by heat, and its congeners afford us two medicines of peculiar utility, the cascarilla

and the castor oil, both however from plants poisonous in some parts. The poison of the cassada root is a white milky fluid, highly deleterious. It is found to act as a sedative on the nervous system; for the substance is apparently unchanged, and neither inflammation nor erosion can be discovered in the stomach.

Among the varieties cultivated, those which have a tinge of red or violet are most common and most highly esteemed. The cassada, when dried, will keep fifteen years with little change: and Aublet tells us, that ten pounds are sufficient for fifteen days' provision. On adding water, it swells considerably.

The liquor that is pressed from this plant is called *manihuera*; the root macerated in water until it is soft is called *mandiophiba*; of the sediment of this is made a finer flour, called *velheba* by the Brazilians, and by the Portuguese *farinha fresca*; the undried dressed meal, *farinha relada*.

The soft mandihoca is called *puaba*: when dried over the fire, or in the sun, it is called *carima*; and of this good bread is made, which is called *musam*, or *angu*, or *enfonde*.

The root of the bitter cassada is poisonous when raw: however, it may be deprived of its noxious qualities, which reside in the juice, by heat. Cassada bread is made therefore both of the bitter and sweet, by washing and scraping the roots clean, grating them into a tub or trough, and squeezing out the juice by strong pressure through a hair bag; the thinner part of which is evaporated, and the remainder dried over the fire in a hot stone bason, and afterwards made into cakes. It also makes puddings equal to millet.

The small bits which have escaped the grater, and the clods not passing through the sieve, are dried in the stove after the flour is roasted; then pounded in a mortar to a fine powder, of which is made soup. It is likewise used for making a kind of coarse cassada, which is roasted till almost burnt: this, fermented with melasses and West-India potatoes, forms an intoxicating liquor, a favourite drink of the natives, called *ouycon*. With this liquor the poorer inhabitants and workmen are often intoxicated. It is of a red colour, strong, nourishing, and refreshing; to which the inhabitants are soon and easily accustomed as beer.

Of the cassada are made emulsions, ptisans, &c. which are used in consumptions, dysenteries, fevers, faintings, against poisons and hæmorrhages, both internal and external.

The scrapings of fresh bitter cassada are successfully applied to ill-disposed ulcers.

The fluid pressed from the cassada contains an extremely fine fæcula or starch, of the most beautiful white colour, which, like the starch of wheat, crackles between the fingers—an adventitious quality in the latter, depending, it is said, on spirits of wine employed in the manufacture. The cassada starch is used in the preparation of the most delicate dishes; indeed in every art where we employ the finest flour.

From the cassada, mixed with potatoes, by fermentation, the Americans prepare the *vicon*: it is an agreeable acid liquor, equally pleasant and wholesome. If the juice of a variety of the *jatropha*, the *cachiri*, is boiled with rasped potatoes and sugar, and then fermented, a pleasing liquor resembling perry is produced. By a similar method, a kind of white wine (*paya*) or

cyder (voua-paya) is manufactured. In these processes, the roots of the cassada suffer a degree of decomposition, probably from fermentation, since they are allowed to remain till they are covered with a purple mould. The cassada, boiled with pimento till it acquires the consistence of a conserve, is used as a condiment, and said to be highly agreeable in a variety of sauces.

When the cassada is heated over the fire to separate the poisonous oil, it is usually made into cakes; but it is sometimes broken into small grains, and is then supposed to be the *tapioca*.

The juice of roucou is an antidote to the poison of this plant. Raii Hist. Encyclop. Britannica.

CASSA'LE VU'LNUS. A term signifying a wound in the breast: (from the Arabian word *cassa*, a breast).

CA'SSAMUM. The fruit of the balsam tree.

CASSA'TUM, (from *κασσα*, a harlot; so called from being debilitated by too frequent meretricious commerce). Weak, spiritless; blood that is grumous, and hinders the passage of the circulating blood. It is a word of Paracelsus.

CA'SSAVE, CA'SSAVI. See CASSADA.

CA'SSE, EAU DE, or EAU DE CASSE-LUNE'TTE. It is snow water distilled from the flowers of the cyanus.

CA'SSIA. See CASIA, and also SENNA ALEXANDRINA.

CA'SSIA ALATA, Lin. Sp. Pl. 541. The leaves of this plant are bitter, nauseous in their taste, and supposed to be cathartic. The decoction is recommended in herpes.

CA'SSIA CANE'LLA. See CASSIA LIGNEA.

CA'SSIA CARYOPHYLLA'TA, called also *hiper tavasci*, *caryophyllus aromaticus fructu rotundo*, *garyophillon Plinii*, *amomum*, CLOVE BERRY TREE, SWEET SCENTED JAMAICA PEPPER TREE. The bark is called *cortex caryophylloides*, CLOVE BARK, and *cassia cortex*, CASSIA BARK. *Myrtus caryophyllata* Lin Sp. Pl. 675.

The bark is produced in Jamaica, Cuba, and other of the West Indian islands. It is rolled like cinnamon, but is rather thinner, rougher on the outside, and of a dark brown colour. Cassia bark is warm and aromatic, resembles the smell of cloves, though weaker, and mixt with the flavour of cinnamon; agreeing with cloves in the solubility and volatility of its active principles. Spirit of wine takes up all its aroma, but carries very little of it in distillation. Water takes up its smell, though imperfectly its taste; and, distilled with water, a small portion of an essential oil arises, which resembles that of cloves, but is more pungent.

A similar bark is brought from the East Indies, under the name of *culiltawan* or *culilawan*, a compound Malabarian word, which is translated into the Latin by *cortex caryophylloides*, or clove bark. That distinguished in Europe by the name of *culilawan* is thicker than the other, and more of a cinnamon colour, but scarcely differs in smell or taste. The *carabacium* of Baglivi is probably not very different, and supposed to be a species of *laurus*. Rumphius observes, that the outer and inner barks of different parts of the tree differ in colour and taste from one another; whence, probably, the differences observed in those brought under different names into Europe.

The unripe fruit is the JAMAICA PEPPER. See PIPER JAMAICENSE.

VOL. I.

CA'SSIA FISTULA'RIS, called also *cassia nigra*, *cassia solutiva*, vel *purgatrix*, *chairaxambar*, *canna*, *fistula*, PURGING CASSIA. *Cassia fistula* Lin. Sp. Pl. 540. The ALEXANDRIAN PURGING CASSIA.

The *cassia fistula* is the hard woody cylindrical pod of a tree called PUDDING PIPE TREE, which resembles the walnut tree: it grows spontaneously in Egypt and the warmer part of the East Indies, and hath been from thence introduced into the West, and is brought to us from the Brasils. The pods are about an inch in diameter, and a foot or more in length; externally of a dark brown colour, somewhat wrinkled, with a large seam running the whole length upon one side, and another, less visible, on the opposite side, internally of a pale yellowish colour, divided by thin transverse woody plates, in a number of little cells, containing each a flat-tish oval seed, with a soft black pulp.

The pulp is called by some *medulla*; *cassia cribrata*; *cassia atramentum*, *extractum*, and *flos*; by others, WILD HONEY, because of its sweet taste, which is followed by an ungrateful kind of acrimony; that from the East Indies has a more agreeable sweetness and less acrimony than the West Indian kind. The best pulp is of a shining black colour, sweet taste, with a slight degree of acidity.

The oriental pods are also smaller, smoother, and thinner rinded than the occidental, and its pulp is more shining and of a deeper colour. The dry pods, in which the seed rattles, are generally rejected; but Neumann thinks that they are scarcely worse than the other, as their humidity only is wasted, and it is thus secured from being mouldy or sour. The best sort, if gathered before it is fully ripe, grows mouldy, and becomes sour or harsh.

The pulp of cassia dissolves very readily in water, whether it is moist or dry, but not so readily in spirit of wine. It is usually extracted by boiling the bruised pods in water, and evaporating the strained solution to a proper consistence: the exhaling vapour carries nothing off. The pulp soon turns sour, so that it should be only extracted in small quantities.

Cassia was first used by the Arabians. Where irritating purges would injure, it may be safely employed: in doses of a few drachms it is generally laxative, and particularly useful in costive habits and inflammatory cases. According to Geoffroy, it is peculiarly beneficial in those tensions of the belly which attend an imprudent use of antimonials: as a cathartic, two ounces are required, so that it is seldom used; and, indeed, at present it is rarely given by itself, except to children, or pregnant delicate women. The pulp of prunes is recommended to supply its place, as almost equally pleasant and safe.

It is sometimes quickened by stronger purgatives, or with tartrited antimony, which it decomposes; so that four grains or more of emetic tartar may be taken in a decoction of cassia by those, who, without it, can scarcely bear one quarter of the dose. It is supposed to enhance the purgative virtue of manna: a mixture of half an ounce of cassia with two drachms of manna, is said to purge more than three times the quantity of cassia by itself, or than a yet greater quantity of manna when alone.

Cassia, if repeatedly taken, is said to tinge the urine of a yellow, green, or brown colour, according to the quantity given. Bergius, however, informs us, that an

3 A

ounce was taken for three successive mornings without such effect.

The London college directs the following preparation:

*Electuárium è Cássia*.—Take of syrup of roses, the pulp of cassia, fresh extracted, of each half a pound; of manna, two ounces; of the pulp of tamarinds, one ounce. Beat the manna, and, with a slow fire, dissolve it in the syrup; then add the other ingredients; continue the heat; and reduce the whole to a proper consistence.

This electuary was formerly called *diacassia*: the tamarinds render the taste of it very agreeable, and do not subject it to turn sour. Two or three drachms will prove gently laxative. See Lewis's Mat. Med. Neumann's Chemical Works. Cullen's Mat. Med.

CA'SSIA LIG'NEA; called also *cassia lignea Malabarica*, *xylo-cassia*, *canella Malabarica et Javensis*, *karva*, *canella Cubana*, *arbor Jucadice*, *cassia canella*, *canellifera Malabarica*, *cortex crassior*, *cinamomum Malabaricum*, *carva*, *calihacha*, and by the ancients *canela*, WILD CINNAMON TREE, MALABAR CINNAMON TREE, or *cassia lignea tree*.

The leaves of this tree are, by way of eminence, called *FOLIUM*, which see. The bark is called *cassia lignea*, and is brought from the East Indies. This tree is of the cinnamon kind. It is the *laurus cassia* Lin. Sp. Pl. 528; the *cassia*, or *wild cinnamon tree*. Curtis, in his Catalogue of Medicinal Plants, in the London Botanic Garden, calls it *laurus Malabathrum*. This bark (the best species of which are styled *daphnitis*) resembles cinnamon in appearance, but is distinguishable by its breaking short or smooth, while the fracture of cinnamon is fibrous: and by chewing, when the cassia becomes mucilaginous, but the cinnamon austere and dry. It resembles cinnamon in flavour, but is weaker: it contains a mucilage, of which cinnamon does not sensibly partake; if powdered, and boiled in water, the water becomes glutinous, so as to concreate, on cooling, into a jelly. Of the bark, choose that which is small, purplish, easily broken, fragrant, pungent, sweetish, and mucilaginous when chewed.

Spirit of wine extracts the aroma, and water extracts the mucilage. By distillation in water it yields a small portion of oil, which differs not from that of cinnamon; and if care is taken in distilling it with water, no difference can be discovered from what it produces, and that which is drawn from true cinnamon; but if too much heat is continued at the end of the operation, it occasions an empyreumatic flavour, because of the mucilage, which is very apt to burn. As a cordial, it is equal to cinnamon, if twice the quantity is allowed for a dose; but to astringent powers it has no pretension. See Neumann's Chem. Works. Lewis's Mat. Med. Cullen's Mat. Med.

CA'SSIA POE'TICA LOBE'LLII, *cassia Latinorum*, *cassia ligna Monspeliensium*, and *cassia Monspeliensium*. See OSYRIS.

CA'SSIA LI'GNEA JAMAICENSIS. See CANELLA ALBA.

CA'SSIA ATRAMENTUM et EXTRACTUM. See CASSIA FISTULARIS.

CA'SSIA CO'RTX. See CASSIA CARYOPHYLLATA.

CASSIA'NA. See CASSINE.

CA'SSIBOR. See CORIANDRUM.

CA'SSIDA, (from its resemblance to *cassia*, a hood, or helmet); *Lysimachia galericulata*; *scutellaria galericulata* Lin. Sp. Pl. 835. HOODED LOOSE STRIFE.

LYSIMACHIA CÆRU'LEA GALERICULATA, or *grattola cærulea*, (from *Lysimachus*, the inventor). HOODED WILLOW HERB.

Dr. Turner says it was called *tertianaria*, from its use in intermitting fevers; it is bitter, stinks like garlic, but is never used.

CA'SSIDBOTT. See CORIANDRUM.

CA'SSINA, CA'SSINE; also called *alaternoides Africana lauri serratæ folio*, *Apalachine gallis*, *herba cassiana*, *alaternus*. *Ilex cassine* Lin. Sp. Pl. 181. Nat. order *dumosæ*. It grows in Carolina; the leaves resemble those of senna, blackish when dried, shining in the upper part, and green underneath, with a bitter taste, and an aromatic smell. There are two sorts, and, according to Dale, they are the third and fourth species of *alaternus*. Miller calls the *cassine vera* *Floridanorum*, the SOUTH SEA TEA TREE; and the *Paragua*, the CASSIO BERRY BUSH. Some call the Paraguay, or South sea tea, by the name of BARTHOLOMEW'S HERB. It grows near the sea. The trade for this tea is chiefly at Santa Fé, whither it is brought by the river Plata: there are two sorts, the *yerba de palos*, and a finer and a better sort, called *yerba de camini*. It is most probable that the *yerba de camini* is the Paraguay, or South sea tea, and the *yerba de palos* is our cassio berry bush. The leaves of the cassine are considered as stomachic and stimulant. They are sometimes used as expectorants; and, when fresh, are emetic. Miller's Dict.

CA'SSOB. See ALCALI.

CASSOLE'TA. A kind of humid suffumigation described by Marcellus.

CA'SSONADA. See SACCHARUM.

CA'SSU. See ACAJAIBA.

CASSUMMU'NIAR, called also *bengalle Indorum*, *rysagon*, and *casminar*. The root brought from the East Indies in irregular slices is tuberos, an inch or more thick, marked on the surface with circles or joints like the galangal: it is brown on the outside, and of a dusky yellow within. We have no certain account of the plant from which it is taken.

This root was introduced by Marloe as a medicine of uncommon efficacy in nervous diseases; at present it is used as a stomachic, but not so generally as it seems to deserve. It is warm and aromatic, slightly bitter, in smell resembling ginger, or zedoary, from which it differs in being milder. Spirit of wine extracts all its virtue; and, if the tincture is evaporated, it remains in the extract. Lewis's Mat. Med.

CASSU'TA, (from the Arabic term *kesut*). See CUSEUTA.

CASTANEA. CHESTNUTS, (from *Castana*, a city in Thessaly from whence they were brought). Called also *lohimá*, *mota*, *glans Jovis Theophrasti*, JUPITER'S ACORN, and SARDINIAN ACORN. *Fagus Castanea* Lin. Sp. Pl. 1416. The coat between the kernel and shell is astringent; the kernel is indigestible, and supposed to be astringent; but if roasted and mixed with honey, it is commended for coughs and spitting of blood. See ALIMENT.

CAST'ANEA. FL'ORE AL'BO, &c. See COFFEA

CASTA'NEA EQUI'NA. HORSE CHESTNUT. See HIPPOCASTANUM.

CASTA'NEA CA'STJOE. See TERRA JAPONICA.

CASTLE-LEOD WATERS. This mineral water is found at Castle-Leod, in Ross-shire: and at this place a spring of strong sulphureous water has been in great repute for many years. Dr. D. Monro, in his analysis, found a gallon to contain about 59 grains of solid matter; viz. of absorbent earth  $1\frac{3}{4}$  grain; of selenite  $26\frac{3}{4}$  grains; of saline matter  $30\frac{3}{4}$  grains; the greatest part of which is true Glauber's salt, mixed with a little sulphur, and probably a very small portion of marine bittern. This water is said to be sensibly diuretic, and sometimes to increase perspiration. It increases the appetite, and sits light on the stomach; sometimes occasioning a little headach, but of no long duration, nor to any great degree. Dr. Mackenzie has directed people with various complaints to drink these waters; and observes, that cutaneous eruptions have been cleared by their use, the herpes removed, the erysipelas received benefit, and foul ulcers cured. Dr. Monro asserts, that many of those cutaneous disorders called scorbutic have been removed by their means, and that they cure the itch. As this water contains but a small portion of purging salt, and does not operate by stool, all these virtues are very incredible, and are probably the offspring of fancy or superstition. To render them really useful, some purging salt may be occasionally added to the first glass that is taken in the morning; and if equal parts of this and sea water be mixed, they will form a purging sulphureous water, similar to that of Harrowgate. See Monro, vol. ii. Medical and Pharmaceutical Chemistry.

CASTOR, (quasi *γαστήρ*, from *γαστήρ*, the belly, because of the largeness of his belly; or from *castrando*, because he is said to bite off his testicles, as the supposed object of his hunters). The BEAVER, also called *fiber*, and *canis ponticus*. CASTOREUM RUSSICUM, *materia, in folliculo prope anum sito, collecta*. Pharmacop. Lond. RUSSIAN CASTOR, from the *castor fiber* Lin. Systema Naturæ. It is an amphibious quadruped, inhabiting some parts of Prussia, Poland, Russia, and Germany; but the greatest quantities are found in Canada. In the inguinal region of this animal are found four bags, of an oval shape, a large and a small one on each side; in the two large ones is contained a softish, greyish yellow, or light brown substance, which in a warm dry air grows by degrees hard and brittle, and of a darker and browner colour; this is the *castor* used in medicine. The two smaller bags have a smell much like that of the larger, but contain a softer and more unctuous matter of but little value.

On cutting these bags, when dry, and brought into the shops, they are found full of a brittle friable substance, of a brownish red colour, interspersed with fine membranes and fibres, intimately interwoven. Neumann asserts that the best comes from Prussia; all other writers say from Russia, and it is in hard round bags: an inferior moister sort comes from Dantzic. The worst is from New England, which is in thin long bags.

The Russian castor hath a strong but not agreeable smell; the taste is pungent and bitter; the other sorts are weaker and more ungrateful.

Castor is ranked among antispasmodics, and is certainly, on many occasions, a powerful one. It has been useful almost in every case requiring such remedies, when given in doses of from 10 to 30 grains. In slow nervous fevers it takes off the oppression of the precordia, which is often a very troublesome symptom. It is by no means a stimulant, but seems rather to relieve by a sedative power. From this it is probably useful in stomach complaints: and if it be an emmenagogue, as authors have supposed, it must be in the hysteric and nervous habits, where the discharge has been repressed from spasm in consequence of a fright, or any similar cause. It has been styled also, without sufficient foundation, an aphrodisiac; but its quality of correcting the uneasy irritation of opium in those with whom that medicine disagrees, is an effect more firmly established. It is used in spasms and convulsions of every kind, in the flatulent colic, and in typhus. Joined with camphor, we have found it peculiarly useful near the conclusion of the more purely nervous fevers.

Rondeletius seems to have first made the distinction between these bags or glands of the beaver and his testicles, the part supposed to contain the castor. Alb. Seba remarks, that the Siberian castor is the best, and in succession, the Norwegian, the Swedish, the Polish, and the Canadian. But from whatever country it comes, that which is from a full-grown beaver, hath a fetid, disagreeable smell, an acrid biting taste, a brownish colour, and a friable texture, is the best.

It is adulterated with dried blood, gum ammoniacum, or galbanum, mixed with a little of the powder of castor, and some quantity of the fat of the beaver. But to detect the fraud, we may remark that the genuine follicles arise from one common source; that the matter contained in them is of a firm consistence, and too bulky to be introduced in their natural state: the smell is not so strong as the genuine. It is, indeed, sometimes difficult to distinguish the false from the genuine; but the sophistication is undoubted, when the membranes, pellicles, and fibres, do not appear intermixed with the castor.

This drug does not keep well in powder. Rectified spirit, proof spirit, and water, by the help of a little heat, extract its whole virtue. Rectified spirit takes up the less ungrateful parts, and water the more nauseous. Proof spirit acts equally, though with some difficulty, on both; the sp. ammon. compositus is an excellent menstruum, and in many cases improves its virtues.

The London college directs the following *Tinctura Castoræi*.

Take of Russia castor, two ounces; of proof spirit of wine, a quart: digest for ten days without heat, and then strain. Dose  $\mathfrak{z}$ i. to  $\mathfrak{z}$ iii. Heat only extracts the grosser part more plentifully than a cold maceration, and proof more than a rectified spirit. If it should be wanted to act more suddenly, the tincture of the Edinb. New Dispensatory, 1789, is preferable. R. Castorci Russici  $\mathfrak{z}$ i. asafœtida  $\mathfrak{z}$ ss. sp. sal ammoniac vinos.  $\mathfrak{h}$ i. digere per sex dies.

CA'STOR. See CATAPUTIA MAJOR.

CASTRATIO, (from *castro*, to castrate). CASTRATION. This operation, called also *celotomia* or-

*chotomia*, is performed when the testicle is scirrhus or cancerous. When the testicle suppurates, it is only treated as a common abscess. Mr. Barnard says, that out of a hundred patients that he castrated, only three were living three years after: and that when, after the operation, the wound heals nearly, and not completely, it commonly proves mortal. Some of the most eminent practitioners observe, that when a scirrhus is extirpated, it is apt to return like a cancer in the breast.

But if the testicle must be extracted, first examine whether or not the spermatic cord is free. Should it not be so, the operation is useless. If not diseased, it must be laid bare, tied, and cut; after which all the diseased part of the scrotum must be dissected. If the tumour is large, or if it adheres to the skin, an oval incision must be made, begun a little above the tumour, for the better convenience of tying the vessel.

Mr. Gooch (Cases, vol. 2.) first slits the sheath of the cord with the point of a knife, then opens it further with a small pair of crooked scissors, by which method the vessel is fairly discovered, and easily taken up with a crooked needle and ligature. He adds, that if the whole spermatic cord be tied, the consequences are disagreeable, or perhaps fatal: he, therefore, after dissecting the sheath, secures only the artery, and thus an hæmorrhage is prevented, and the usual consequences of tying the whole cord avoided. Dr. Hunter long since advised to secure the artery, and leave the rest of the cord; and, indeed, he suggests a sufficient security though the artery should be left untied; though if it is to be cut close to the ring, he advises to tie it before cutting, that it may not retract too suddenly, and prove troublesome by its discharge. Perhaps the scrotal arteries should be secured previous to the operation. After it, the patient should be kept perfectly quiet, and the wound healed, if sufficient integuments can be saved by the first intention. See Sharpe's Operations. Le Dran's Operations, and his 74th Obs. Heister's Surgery. Bell's Surgery, vol. i. p. 520.

**CASTRATUS**, (from *castro*, to castrate). In botany it means having the filament without the anthera, or part which contains the dust of impregnation. In medicine, those unhappy beings who, to preserve the voice from the changes produced by puberty, are thus mutilated in early infancy. In the East, the same operation is practised to qualify them as safe guardians of the women.

**CASTRENSIS**. See **DYSENTERIA**.

**CA'SUS**, (from *cado*, to fall out, or occur). This word signifies the same as *symptoma*; but sometimes any thing fortuitous or spontaneous; or a fall from an eminence. In Paracelsus it signifies a present distemper, as well as an entire history of a disease.

**CATABALAM**. See **AMBALAM**.

**CATABLEMA**, (from *καταβάλλω*, to place round). The outermost fillet which secures the rest of the bandage; also *fimbria*. Hippocrates, *secundum Galenum*.

**CATACHLO'OS**, (from *κατα*, and *χλωω*, to make green). Galen styles it 'a very green colour.' It is applied to stools; and then **CATACHOLA**, very bilious, will be synonymous.

**CATACHRI'STON**, (from *καταχρίω*, to anoint). A medicine applied by way of unction.

**CATACHY'SIS**, (from *κατακλειω*, to pour out). An affusion.

**CATACLA'SIS**, (from *κατακλαω*, to break or distort). Galen explains it to be a distortion of the eyelids. Vogel defines it to be a spasmodic occlusion of the eye.

**CATACLE'IS**, **SUBCLAVICLE**. According to Galen it is the first small rib of the thorax; from *κατα*, below, *κλεις*, *clavis*, the clavicle.

**CATACLI'NES**, (from *κατακλινω*, to lie down). See **CLINICUS**.

**CATACLY'SMA**. See **ENEMA**.

**CATACLY'SMUS**, (from the same). **EMBROCA-TION**. Cælius Aurelianus also interprets it by *illisiones aquarum*, dashing of water.

**CATACONE'SIS**, (from *κατακοναω*, to irrigate). Irrigation by a plentiful affusion of liquor on some part of the body.

**CATA'CORES**, (from *κατακρεννυμι*, to supersaturate). Full, abundant; and when applied to stools, it means that they are purely or intensely bilious. Hippocrates uses it in both these senses.

**CATAGE'MU**. See **GAMBOGIA**.

**CATAGLY'PHE**, (from *γλυφω*, to cut in wood or metal). An excavation, hole, or pit. Hippocrates uses this word, *De Art. et de Morb.*

**CATA'GMA**, (from *κατα*, and *αγω*, to break). A **FRACTURE**. See **FRACTURA**. Galen says, 'a solution of the bone is called *catagma*, and *elcos* is a solution of the continuity of the flesh; that when it happens to a cartilage it hath no name, though Hippocrates calls it *catagma*. See **ALPHITEDON**.

**CATAGMA'TICA**, (from *καταγνυμι*, *κατα*, *contra*, *αγνυμι*, *frango*). Remedies proper for cementing broken bones, or to promote a callus.

**CATAGO'GE**, (from *καταγω*, *deduco*.) In Hippocrates' *Epid. lib. vii.* it means a region, and its circum-jacent part.

**CATALE'NTIA**. See **EPILEPSIA**.

**CATALE'PSIS**, **CATALEPSY**, (from *καταλαμβάνω*, to seize, or interrupt). It is also called *catoche*, *catochus congelatio*; and by Hippocrates, *aphonia*; by Antigènes, *anaudia*; by Cælius Aurelianus, *aphrehensio*, *oppressio*; also *apoplexia cataleptica*, *detentio*, *encatalepsis*, *comprehensio*.

The word *catalepsis* hath many significations, as perception, or the knowledge of a thing; the retention of the breath, as when a person strains at stool; a retention of any humour which ought to be evacuated; an interruption of the blood in the vessels by a bandage, and the disease which is the subject of this article. The *catoche* is sometimes supposed to be the coma vigil; but most writers mean by it the *catalepsy*.

This disorder, with the carus, may be ranked among the species of apoplexy. Dr. Cullen considers it as such, and adds the following remark: 'I never saw any catalepsy but what was counterfeited; and the same has been seen by others. Therefore from the disease being seldom seen, differently described, and often altogether feigned, I know not in what place to fix it with certainty; but, as I am persuaded in general it does not differ from apoplexy, I have therefore placed it under that head,' viz. *apoplexia cataleptica*, when the muscles are contracted upon being moved by external force. Its seat seems to be in the back part of the brain, from the symptoms of the disease, and the

observations made on dissecting those who die of it. Indeed its subjects, and, perhaps, the symptoms, do not essentially differ from chorea, since the tonic and clonic spasms originate from the same or similar causes; and chorea we shall find to be truly apoplectic.

Women of a melancholy habit and a very active imagination are most subject to it, especially if exposed to bad weather in cold climates after being heated.

The immediate cause of this and other spasmodic diseases, is an irregular distribution of the vital influence from debility. The predisposing cause is an irritable system; and the exciting suppressed perspiration, or a disordered stomach: noxious vapours, and bad smells, have been accused, but, we suspect, without sufficient foundation.

This disorder rarely occurs: the fits generally seize the patient at intervals, and last usually a few minutes, though sometimes they continue for some hours or days. It is rarely preceded by any signs that indicate its approach; in a few instances a stiffness in the neck, or a dull pain in the head, has ushered in the fit. In the disorder the patient is without sense or motion, continuing in the posture in which the fit attacked him, until a recovery from it: the limbs are moveable by another person; but, however they are disposed, the patient never alters their position until the paroxysm is at an end. He neither sees, hears, nor feels, whatever methods may be used to excite the sensations. He swallows greedily all that is given him; the countenance becomes florid; the eyes are open, seemingly fixed upon some object; at the close of the fit he fetches a deep sigh, and then recovers. Other symptoms attend different patients, or the same at different times, such as tears dropping from the eyes, grinding of the teeth, &c. but the above are the most general.

Care must be taken not to confound a *cataplexy* with a tetanus: the latter begins with a stiffness of the neck, which gradually extends to every muscle, and every limb is immoveably rigid.

If this disease proceeds from passions, the danger is not so great as when suppressed accustomed evacuations, or a foul stomach, are the causes: from suppressed evacuations it is mostly fatal. In general the cure will be similar to that of the apoplexy. The indication in the fit is, to relax the spasmodic stricture; and, out of the fit, to remove the material or secondary causes, which contribute to the production of the constriction.

In the fit, pungent acid spirits, such as the acetic acid, or the strongest wine vinegar, may be applied to the nose. Forestus strongly recommends antispasmodic oils to be rubbed on the nape of the neck, and on the back part of the head after shaving it. Strong stimulating clysters may be injected, if the anus is not too much constricted to admit them.

Bleeding is commended, if the face is very red and turgid; but, the heat and strength of the patient will best determine the propriety of this operation. Blisters, though recommended, seem not so eligible an application as sinapisms to the feet. Two or three spoonfuls of the following mixture may be given at proper intervals, either during the fit, or in its absence.

R. Gum ass. fœtid. ʒ ij. aq. puleg. ʒ iv. sp. ammoniæ fœtid. and tinct. valer. vol. ʒ ʒ ss. m. The fit is generally transitory, and never fatal.

In the absence of the fit, the remedies will be indicated by the remote causes. The bowels should, in every instance, be kept regularly and freely open. If, however, fears or other passions of the mind are the causes, medicines cannot be expected effectually to relieve; but, in such cases, a change of air, travelling, diverting company, &c. are to be insisted on. Electricity has been recommended, and cures from its employment have been recorded. The metallic tonics have also been recommended, particularly the copper and the zinc, though seemingly from no real trials.

The cataplexy sometimes ends in a melancholy, epilepsy, or fatal apoplexy.

See Cœlius Aurelianus, Acut. ii. x. Hoffman. British Magazine for March, 1800, and the following numbers. Journal des Savans, Jan. 1776. Histoire de l'Academie des Sciences, 1738; and Mémoires pour 1742.

CATALO'NGAY. The plant that bears the *faba sancti Ignatii*.

CATA'LYSIS, (from *καταλυω*, to dissolve, or destroy). It signifies a *paralysis*, or such a resolution as happens before the death of the patient; also that dissolution which constitutes death.

CATAME'NIA, (from *κατα*, *secundum*, according to, and *μην*, *mensis*, the month). See MENSES.

CATANA'NCE. See CICHORIUM.

CATANTLE'MA, (from *καταντλαω*, to draw, or pour water upon). A kind of lotion by infusion in water. Moschion de Morbis Mulierum.

CATANTLE'SIS, (from the same). A lotion with hot water, expressed out of sponges, recommended by Marcellus Empiricus against irritable running ulcers of the head.

CATAPA'SMA, CATAPA'STUM, (from *καταπασσω*, to sprinkle upon). The ancient Greek physicians meant by this term any dry powder, to be sprinkled on the body; called also *conspersio*, *epiphastion*, *phasma*, *symphasmata*, *aspersio*, *aspergines*; their various uses may be seen in Paulus of Egina, lib. vii. cap. xiii. Powders valued for their grateful smell were called diapasms; and these were sometimes added to the drink. Oribasius shows from Antyllus, that *emphasmata* were used in order to restrain sweat, or any other evacuation by the pores; or for exciting an itching. *Cataplasms*, varied according to the intention of the physician, were sprinkled on ulcers; but diapasms were prepared for the sake of their scent, and were applied to the arm pits, and the inside of the thighs. Cœl. Aurel. in Morb. Acut. lib. ii. cap. xxxviii. says, that *symphasmata* were such powders as, being endowed with an acrid quality, were sprinkled on the body to procure heat.

CATAPA'SMUS. A term used by Cœl. Aurelianus, probably by mistake, for some other word. It implies, according to him, a rubbing of the posterior part of the shoulders and neck downwards.

CATAP'ELTES, (from *κατα*, against, and *πτελην*, a shield,) a grenado, or battery: it signifies also the medicine which heals the wounds and bruises made by such an instrument.

CATAPHI'SMA. A thick poultice of meal and herbs.

CATA'PHORA, (from *καταφωρω*, which, among other significations, implies to render sleepy). A pre-

ternatural propensity to sleep. See CAROS. Galen calls a coma by this name.

CATA'PHORA CO'MA, i. e. *Aphoplexia*.

CATA'PHORA HYDROCEPHA'LICA, i. e. *Aphoplexia serosa*. See HYDROCEPHALUS.

CATAPHRA'CTA, (from *καταφρασσω*, to fortify). See QUADRIGA.

CATAPLA'SMA, a POULTICE, (from *καταπλασσω*, *illino*, to spread like a plaster,) also *malagma*, *epihasma*, *epiplasma*. *Cataplasms* take their name sometimes from the part to which they are applied, or effects they produce, so are called *anacollema*, and *frontale*, when any topical application of this sort is laid upon the forehead; but the former were always made of agglutinants. They were styled *epicarpia*, and *pericarpia*, when applied to the wrists; *epispastica*, when the external remedies only inflamed the skin; *vesicatoria*, when it occasioned blisterings; and *sinapismata*, when mustard chiefly composed them, and the consequences were irritation, redness, itching, and tumour, in the parts to which they are applied. See BLISTERS.

These kind of applications are softer and more easy than plasters or ointments. They are formed of some vegetable substances, and applied of such a consistence as neither to adhere nor run: they are also more useful when the heat is to be preserved, or its access prevented. See CALORIC.

When designed to relax, or to promote suppuration, they should be applied warm. Their warmth and moisture contribute to this purpose. The proper heat, when applied warm, is that only which excites a pleasant sensation; for great heat prevents the relaxation for which they are applied. (See BALNEUM.) They should be renewed as often as they cool. For relaxing and suppurating, none excel the white bread poullice, made with the crumb of an old loaf, a sufficient quantity of milk to boil the bread in until it is soft, and a little oil, to prevent the poullice from drying and sticking to the skin, and, perhaps, to retain the heat longer than the bread and milk alone would do. The meal of lintseed is often employed, as it contains the oil intimately united with the farina. To preserve the heat longer, the poullice, when applied, may be covered with a strong ox's bladder.

When designed to repel, they should be applied cold, and ought to be renewed as oft as they become warm: a proper composition for this end is a mixture of oatmeal and vinegar. Epithems are also a kind of *cataplasms*.

The *emollient poullice* is made by boiling half a pound of the crumb of bread with one ounce of white soap in a sufficient quantity of cow's milk, to reduce the whole to a proper consistence. Amongst the poor, the bran from wheat may be used instead of bread, adding a small quantity of oil or lard to it.

The *discutient poullice* is made with barley meal, six ounces; the leaves of hemlock fresh gathered and bruised, two ounces; crude sal ammoniac, half an ounce; vinegar enough to give the whole a proper consistence. These ingredients should be mixed without heat, and applied cold.

CATAPLA'SMA EFFERVE'SCENS. Stir into a strong infusion of malt as much oatmeal as will make it of a proper consistence, then add a spoonful of yeast, and

mix them well together. By this mode, fixed air is applied to ulcers, cancers, and other local affections requiring powerful antiseptic remedies. In the application, room must be left by the bandages sufficient to permit its expansion, which, from the fermentation, will be considerable, or the bandages must be carefully watched, and occasionally slackened.

CATAPLA'SMA ALU'MINIS. See COAGULUM ALUMINIS.

CATAPLA'SMA ACE'TI. See STREMMIA. There are a variety of other cataplasms, all which will be found under the respective ingredients from whence they are denominated; as, CATAPLA'SMA RO'SÆ, CU'MINI, &c. See ROSA, CUMINUM, &c.

CATAPLE'XIS, (from *καταπλησσω*, to strike). A sudden stupefaction, or deprivation of sensation in any of the members or organs.

CATAPO'SIS, (from *καταπινω*, to swallow down). According to Aretæus it signifies the instruments of deglutition. Hence, also,

CATAPO'TIUM, (from the same). A PILL. See PILULA.

CATAPSY'XIS, (from *καταψυχω*, to refrigerate). A coldness without shivering, either universal or of some particular part. A CHILLNESS; or, as Vogel defines it, an uneasy sense of cold in a muscular or cutaneous part.

CATAPTO'SIS, (from *καταπιπλω*, to fall down). It implies such a falling down as happens in apoplexies; or the spontaneous falling down of a paralytic limb, expressed often by *decidentia*.

CATAPULT'ARUM, AQUA. See ARQUEBUSADE. It is the same as CATAPELTES.

CATAPU'TIA. SPURGE, (from *καταπυθω*, or the Italian term *cacapuzza*, to have an ill flavour). Under this name are ranked the CATAPUTIA MAJOR; called also *palma Christi*, *alkerva*, *figus infernalis*, *pentadactylon*, *granadilla Peruviana*, *ricinus vulgaris*, *agnus castus*; *kiki*, *ricinus Americanus*, *nhambu guacu* of Piso, *cherva major*; COMMON PALMA CHRISTI, GREAT SPURGE, MEXICO SEED, *castor*; *ricinus communis* Lin. Sp. Pl. 430. It is of the natural order of *tricocœæ*, and nearly allied to the *croton* and *jatropha*. The order of Jussieu is the *tithymaloides*.

This plant sometimes rises in one year to the height of twenty feet, and is spread into many branches; the leaves expand like a hand, with the fingers a little separated: the flowers are small and in bunches. On the body of the plant there are clusters of rough triangular husks, each containing three speckled seeds about the size of small kidney beans, and in their shells are white kernels of a sweet, oily, and sometimes of a nauseous, taste.

These seeds are called *grana ragium*, and were used by Hippocrates, and perhaps before him. If taken in substance they are acrid, and purge violently; but the oil expressed from them acts gently, though generally with effect.

The leaves, when beat and boiled in milk to the consistence of a poullice, are powerful suppurants, used for dressing blisters, and applied to the tinea of children.

The seeds are externally variegated with black and whitish streaks, resembling both in shape and colour the insect called *ricinus*, the tick, whence the name

ricinus is given to the plant. The oil is the most valuable part, and is obtained both by expression and decoction; the latter is preferred as more mild in its operation.

This oil is known by the names of *ol. ricini*, *alkerva*, *ol. palmæ Christi*, *oleum cinum kerva*, OIL OF AGNUS CASTUS, and CASTOR OIL. The Greeks call it *Αιγυπλίον ελαιον*, *oleum Egyptium*.

This oil operates soon after its exhibition, often in two or three hours: it seldom gripes, or gives more than two or three stools. It is particularly suited to the cure of costiveness and of spasmodic colic. It is not heating or irritating to the rectum, and consequently well suited to cases of hæmorrhoids; besides its easily operating as a purge, it is of peculiar use in bilious constitutions, in febrile disorders of the same kind; and, by joining it with proper cordials, may be used in the low and putrid fevers. Its efficacy exceeds all other kind of purging medicines in calculous complaints, and in all such cases as require the bowels to be moved, and yet forbid the use of powerful stimulants. In colics, without addition, it is seldom sufficiently active; and even in fevers, as it does not greatly excite the action of the muscular fibres of the intestines, it often passes over collected scybala. See CATHARTICS.

To children it may be given in the manner of an oleo saccharum. Gooch, in his Medical Observations, commends the following method of administering it to adults, and assures us, that two or three spoonfuls, taken occasionally at bed time, keep the bowels soluble, even when the bleeding piles attend. A larger dose, or the above more frequently repeated, is sufficient for a purge on any occasion.

R. *Ol. ricini* ℥i. ss. vitel. ovi parum, probe contritis adde sensim aq. menth. pip. et aq. cinnam. āā. ℥ij. syr. rosæ, ℥ ss. m.

In the colic, a table spoonful of this oil may be mixed with a little peppermint water, and repeated every half hour, or every hour, until it promotes the desired evacuation. If the stomach rejects it, the irritability of this organ, should the necessity of a discharge not be urgent, may be previously corrected by opium.

In fevers it is cooling and laxative; but in the lower kind of fevers it requires the addition of an aromatic. In the yellow fever of the West Indies it is very useful. When the belly is already too lax from acrid bile, this oil sheaths the acrimony, and thus restrains the excessive discharge; in dysenteries it relieves by a similar power. If the symptoms of nephritic complaints and the properties of this oil are considered, its use in those complaints will be obvious, for it purges in small quantities, without irritation; it is cooling, and allays febrile heat; it corrects acrimony, and prevents the cohesion of calculous concretions. In gonorrhœas, the fluor albus, the constipation peculiar to studious and sedentary persons, &c. this oil is of singular efficacy. The more resinous purgatives often leave costiveness, but the castor oil, it is said, after little use, acts even in less doses. The best method of preventing sickness or nausea, which it sometimes occasions, is to mix one part of tincture of senna to three parts of the oil. In this state the oil is less nauseous to the taste, and sits more easy on the stomach. It is sometimes taken in coffee, sometimes in mutton broth; frequently in an emulsion, mixed by means of the yolk of an egg, with

some spirituous water, or while swimming on peppermint water. The dose is a table spoonful, or ℥ ss; but some require double the quantity. Where the oil is rejected, the seeds may be carefully separated from their shells and the inner white membrane, and formed into an emulsion, as an agreeable substitute for the oil.

The oil of a pale colour, limpid, and rather inclining to a greenish cast, almost insipid to the taste, with but little smell, and of a thickish consistence, is the best. See Lewis's Mat. Med. Lond. Med. Obs. and Inq. vol. ii. Canvane's Diss. on the *Ol. Palmæ Christi*. Med. Mus. vol. iii. Cullen's Mat. Medica.

CATAPU'TIA MI'NOR. GARDEN SPURGE. Also called *lathyrus major*, and *tithymalus latifolius*.

All the *spurges* are acrid: the milky juice, in which their virtue lies, is caustic and cathartic; the root, or bark, prepared by infusion in vinegar, hath been given in the dose of a drachm; three or four of the leaves purge strongly; the milky juice is said to destroy warts; but none of this tribe are now used, because of their excessive acrimony.

Under this article may be ranked the three following, viz.

RICINOIDES (from *ricinus*, the tick, and *ειδος*, form; from its likeness to that reptile). The BARBADOES NUT; *jatropha curcas* Lin. Sp. Pl. 1429. Also called *pineus purgans*, *pinhones Indici*, *carcas nux Barbadosis*, *fabia purgatrix*, *carpata*, *chiviquilenga*, *ricinus Americanus major semine nigro*, *mundu bignacu*. The fruit is oval shaped like a walnut, and contains oblong black seeds. The tree is a native of America, and also of the East Indies; it grows to a considerable size. The seeds are extremely acrid, and afford an oil that purges, but is rarely used, on account of its activity.

AVELLANA CATHARTICA, or PURGATRIX. The PURGING NUT. *Jatropha multifida* Lin. Sp. Pl. 1429. The tree is a native of America and the West Indies; and grows to a considerable size. Its fruit is oval shaped, containing roundish, and somewhat triangular, brownish seeds, which have but little acrimony, and taste like almonds, but yet operate briskly by vomit and stool.

GRA'NA TI'GLIA. *Croton tiglium* Lin. Sp. Pl. 1426. The MOLUCCA GRAINS, so called because they were first brought from the Molucca islands. They are also called *croton*, and *pinus Indica nucleo purgante*. The tree is a native of America and the East Indies; the fruit is roundish, containing dark greyish seeds; shaped nearly like those of the palma Christi. They are intensely hot and acrid, operate with a degree of virulence both upward and downward; and of the four sorts above mentioned, this is the most active. One drachm of the oil is a strong dose.

The wood and leaves of the above five trees and plants are strong cathartics. Hermann says, that the wood of the tiglia, called *panava*, or *pavana*, operates violently when fresh, but when long kept is sudorific.

CATARA'CTA. A CATARACT, (from *καταρσσω*, to mingle together, or put out of order; because the sense of vision is confounded if not destroyed). Dr. Cullen places it as a species of caligo, and names it CALIGO (*lentis*) ob maculum opacum pone pupillam; and observes, that he cannot agree with Sauvages, that a cataract should be of a different genus from caligo; and leaves it to the judgment of others to determine

whether he has been right in changing the character of caligo, and placing cataract as its species.

A cataract is an opacity of the crystalline humour of the eye, which stops the rays of light from passing to the retina, and preventing vision. Dr. Hunter attributes the disease to an inflammation in the coat of the crystalline humour; but M. de St. Yves seems to intimate that the crystalline humour is itself affected.

Hippocrates called it *glaucoſis*. Galen, *hypochyſis*, and *hypochyma*; the Arabians, *gutta opaca*; others, *macula oculorum*. Celsus, *suffuſio*. It sometimes has the term *affuſio* applied to it; and *γλαυκωσις*, or *γλαυκωμα*, which Galen and most of the ancients say is a dryness or concretion of the crystalline humour. Ætius thinks it a change of the crystalline humour to a sky colour, with a dryness and concretion. More modern authors think that the principal difference betwixt a cataract and a *glaucoma* is, that in the latter the crystalline humour becomes hard, and of a sky colour (*glauci coloris*); and in the former it is soft. But the idea of cataract is now totally cleared from all that confusion in which it was usually involved; *it is universally allowed to be an opacity of the crystalline lens, or its capsule*.

M. de St. Yves divides the cataract into the true, doubtful, and false.

The **TRUE** is when the crystalline humour hath lost its transparency: and the species are, when it is soft; when hard; and when purulent.

The **DOUBTFUL** are those cases in which the success of the operation is as uncertain as the use of topical remedies. Of this there are four sorts: a membranous and a filamentous cataract; cataracts from external injuries; and from a defect of the membrane which covers the bottom of the socket in the vitreous humour. The first and third of these he subdivides again, each into three kinds, as he endeavours to be minute, as well as full, in his description of this disorder.

The **FALSE** are those in which the remedies afford no relief further than to palliate pains, or to remove deformity; and these he divides into the *glaucoma*, and the shaking cataract.

All these minute divisions seem little regarded in present practice; but yet some useful hints will be derived by a perusal of this author.

When a cataract begins, the patient at first complains of a dimness of his sight; and on a careful examination of the eye, a whiteness is perceived very deep in it: on examining the eye at distant periods of time, its opacity becomes more and more manifest to the observer, and the patient very sensibly loses the advantages of seeing. The progress of a cataract is usually very slow.

No medicines are capable of removing this disorder of the eye; but it is sometimes relieved by copious, general, or topical evacuations; sometimes by small doses of muriated mercury, long continued; by drawing electrical sparks, or even by dropping a little of the tincture of opium at night into the eye; in short, by every means of increasing the action of the smaller vessels. The sight, however, can only be restored by an operation.

Sauvages enumerates no less than five species, and of the *cataracta vera* six varieties. He tells us, that two patients were cured by the internal use of the hyos-

cyamus: one of the species which he inserts under the title of membranacea is very doubtful. He says, that it was discovered by Lower on horses, and arises from a mucus exuding from the margin of the pupil, or uvea, which concretes sometimes into a membrane that obstructs the pupil; but whether this membranous cataract exists in the human species, he thinks uncertain, notwithstanding it has sometimes been suspected. See Sauvages Nosologia Methodica, vol. ii. p. 723.

Mr. Sharpe gives it as a general rule for proceeding to the operation, when the cataract is entirely opaque; adding, that sometimes they are of a proper consistence for the operation before they become opaque; but forbids the attempt while the patients can perceive any thing. Cataracts are of different colours; the pearl coloured, and those that appear like burnished iron, are thought capable of enduring the needle; the white are supposed to be milky; the green and yellow are horny, and incurable; the black cataract Mr. Sharpe thinks is the *gutta serena*.

The yellow cataract often adheres to the iris, so as to be incurable. When a *gutta serena* attends, the operation will not relieve. There is little to be expected from the operation when the size of the diseased eye is either diminished or increased; when, previously to the appearance of any obfuscation, the sight was defective; when in a strong light, of which, from the appearance of the cataract, the patient must be seemingly sensible, no contraction of the iris takes place.

The methods of operating are different. By the first and oldest plan, the thickened crystalline was depressed below the vitreous humour; and it was styled *couching*, from *coucher*, to lie down. In the second, the crystalline is extracted.

Before and after the operation, a due regard must be paid to the state of the patient's constitution; and such means are generally advised, as will keep it somewhat below its natural vigour, if otherwise in health.

When no objection to the operation attends, Mr. Sharpe commends the following method for depressing the cataract. "Place the patient in a convenient light, and a suitable height; put a pillow behind his back, that his body may bend forward, and the head approach near to the operator; then inclining the head a little backwards upon the breast of the assistant, and covering the other eye, so as to prevent its rolling, let the assistant lift up the superior eye lid, and the operator depress a little the inferior one: this done, strike the needle through the tunica conjunctiva, somewhat less than one-tenth of an inch from the cornea, even with the middle of the pupil, into the posterior chamber, and gently endeavour to depress the cataract with the flat surface of it. If, after it is dislodged, it rises again, though not with much elasticity, it must again and again be pushed down. If it is membranous, after the discharge of the fluid, the pellicle must be more broken and depressed. If it is uniformly fluid, or exceedingly elastic, we must not continue to endanger a terrible inflammation by a vain attempt to succeed.

"After the operation, treat it as an ophthalmy; and a collyrium, of one part rectified spirit of wine, and ten parts of lukewarm water, will be as proper an application as any."

Mr. Daviel has the honour of having discovered the method of extracting the crystalline humour, but M.

le St. Yves practised it about sixty years before him. When the crystalline lens had passed through the pupil into the anterior chamber of the eye, both Mery and Petit extracted it; for then the depression is impracticable. When this mode of relief is employed, the following method is recommended.

Pass your knife through the cornea into the anterior chamber of the eye, about a line before the iris; for if it is not inserted there, the iris will perhaps be wounded: if you go too far on the cornea, the knife may pass between its lamina, and so not perforate into the chamber. After puncturing into the chamber, guide your knife, with the flat side perpendicular to the eye, through the aqueous humour horizontally, (being careful not to wound the iris,) and thrust it out at the opposite side and situation of the cornea to those in which you insert it; turning its edge obliquely and perpendicularly outwards, make an incision rather through the inferior half of the cornea; then lifting up the superior part of it, the crystalline humour will burst its capsule and drop out: but if it should stick at its exit through the wound, it shows that the capsula of the crystalline is not broken, on which you must puncture it with the knife, and then it will drop: but if the disease is in the aranea, or the capsule of the crystalline, you must extract it also with the forceps.

With respect to the nature of this disorder, or the state of the crystalline lens, whatever improvements have been made within the present century respecting its disordered state, many difficulties still attend. Mr. Pott observes, that, until about the year 1720, neither the state, nature, nor seat of this disease, was truly known, at least not to those who practised surgery. Accident, he adds, first proved it to be a distemper of the crystalline lens, and to be in general confined to it. Heister is the first writer who leads to any just idea on the subject. Mr. Pott seems to be the first who explains the true state of the crystalline humour, when a cataract is formed. He says, that the idea of a beginning or imperfect cataract being soft, and that of a mature or perfect cataract being hard, is erroneous; at least for the most part: that the natural sound transparent crystalline is very far from being uniform in its consistence through its whole substance; its external part is much softer, and more gelatinous than its internal, which, therefore, although equally transparent, may be said to form a kind of nucleus, and is always of a much firmer texture. He adds, if this known difference of consistence between the external and internal parts of the crystalline was duly attended to, it would solve many of the appearances in cataracts, which, for want of such attention, are either not at all or imperfectly understood. Among other phenomena, it would account for the very different colour which the different parts of the same cataract frequently bear; and which hath furnished the wildest conjectures. From this sound and natural state it is capable of several morbid alterations; it is capable of being dissolved, or of becoming a fluid, without losing any thing of its transparency. It hath been supposed, by very able anatomists, that the human crystalline has sometimes between its surface and its capsula, a small quantity of fine pellucid lymph, and consequently that there is no immediate connection between the body and its investing membrane. In many

beasts, as well as fishes, this is known to be the case; but whether it be so in the human eye is not very easy to be known during life; though it sometimes happens from disease: that is, the whole crystalline is dissolved into a fluid, which still preserves its transparency; and this seems to form what is called the black cataract, which is a species of the gutta serena. Mr. Pott goes on to observe, that the crystalline humour is capable of being dissolved into an apparently uniform fluid of a gelatinous consistence, which will be more or less opake through the whole of it: it sometimes becomes opake while it undergoes a partial dissolution, which leaves or renders its different parts of very different degrees of consistence; and it now and then, though very rarely, becomes opake through its whole substance, and yet preserves its natural degree of firmness. From this variety of alteration, which the crystalline humour is capable of undergoing, proceeds that variety of appearance which our ancestors have called so many different kinds of cataracts. The idea of beginning cataracts being soft, and hardening as they become more perfect, hath had an unfortunate influence on practice. When the crystalline humour becomes softer than it should be, it is certainly distempered, and unfit for perfect vision, whether it be opake or not; but that this softened lens will ever be harder we have no more reason to think than we have evidences that an opacity is a proof of its induration. The most fluid cataracts are as opake as the most firm ones. If the early or unripe state be supposed an improper one for the operation, and that the patient must wait for a later or ripe one; it then becomes a matter of consideration, whether the patient shall or shall not continue blind for a very uncertain space of time, or perhaps be ever relieved. Besides the body of the crystalline lens, its capsula or investing membrane may be the seat of the disease; it may become opake, while its contents are clear and duly transparent. This may happen after the operation for depressing a harder cataract, or for discharging a softer one. When the capsula is the seat of the disease, and it takes place after depressing or extracting the crystalline lens, it sometimes vanishes in a few weeks, but occasionally requires an operation.

Respecting the operation of couching, Mr. Pott observes, that as in some instances the cataract remains always fluid, so in others it becomes instantly indurated; whence it follows, that there is no point of time for which we should wait; but at any time when, on other accounts, the object is a proper one, the surgeon may proceed. Previous to the operation, it is right to know the circumstances which render it likely or unlikely to succeed. That it may succeed, the crystalline humour should be opake, and all the other parts of the eye capable of performing their functions; the eye should be of its natural size: when, with the cataract, the globe of the eye is manifestly enlarged, the patient is incapable of perceiving light, or distinguishing betwixt light and darkness, in such a case, the operation must be omitted. The pupil ought to be capable of contracting and dilating. It hath been generally supposed, that when the pupil is immoveable it is useless to perform the operation, which is not in every instance true: the operation certainly should not be performed if the pupil is immoveable from a para-

lysis of the part, nor if it adheres to the crystalline; as in these cases we could not operate with any success: but if it is immoveable, or almost so, from a distention of the crystalline humour, (which Mr. Pott thinks sometimes happens,) the operation may be performed: in these cases, however, on a very nice examination, the pupil will be found to have a very small degree of motion. The patient ought always to be able to distinguish light from darkness, and a white from a black body; if he is not, though you remove the cataract from the pupil, yet the retina is incapable of performing its office. In the following instances, success is hardly to be expected by either couching or extracting the crystalline body; viz. when the diseased crystalline is somewhat of the colour of brass, or of a bright yellow, or of a copper colour; the pupil being generally found immoveable, and the whole eye enlarged. When all the parts of the eye are enlarged, or when the crystalline protrudes through the pupil, the case is not proper for the operation.

Those who undertake to perform either operation will, undoubtedly, have availed themselves of all the information given by the best writers on these subjects; and to those who wish for fuller directions, the subjoined writers are those from whom the whole of what art hath taught will be received.

CATARA'CTA NI'GRA. See AMAUROSIS.

CATARIA, CAT MINT, (from *catus*, a cat; because they are fond of it). See MENTHA CATARIA.

CATARRHALIS FEBRIS AMPHEMERINA, (from *catarrhus*, because this fever is accompanied with, or proceeds from, a catarrh). The CATARRHAL FEVER, or CONTINUAL QUOTIDIAN of the ancients. It begins in the evening, with a shivering and a coldness of the skin and extreme parts, costiveness, frequent desire of making water, but the urine is small in quantity; weakness of the head, universal languor, a capricious and irregular appetite, thirst, difficulty of swallowing, stimulus on the larynx, a heat in the nostrils and fauces, attended with sneezing, and a weight in the breast. Towards night, heat, and a quicker, fuller pulse; cough, with a defluxion of rheum, a heat in the fauces, unquiet sleep, sweating in the morning, and at length a total loss of appetite. In the forenoon there is generally a remission, and it thus appears of the quotidian type.

The cause is a fever, with inflammation on the membrane of the nostrils, throat, and bronchiæ, occasioning the secretion of a sharp, acrid serum, which irritates every part of this membrane, and sometimes the œsophagus, stomach, and intestines; a cough, hoarseness, spitting of a viscid matter, sneezing, a defluxion on the lungs, nausea, and colic followed by a salutary flux, are often the consequences.

Women, children, and weakly men, are its chief subjects. It is most frequent in spring and autumn, or in very variable seasons. After a few days, a catarrh

comes on; and as soon as its discharge appears at the nose, the symptoms of the fever go off: sometimes, indeed, a copious perspiration relieves, and at others a large discharge, thrown up from the lungs; or, perhaps, a diarrhœa proves the natural means of cure.

If we do not wait for these, we must relieve the fever by the more common means of emetics and cathartics, and thus supersede the deposition on the lungs. In fact, from the neglect only of these more general remedies it becomes a catarrhal fever. If these are neglected, the remedies are the same as in catarrh. See CATARRHUS.

CATARRHE'UMA, (from *καταρρέω*, to flow from). See CATARRHUS.

CATARRHEXIS, (from *καταρρήννω*, to pour out). A violent and copious eruption or effusion. Catarrhexis, *κοιλίης*, is a copious evacuation from the belly, and sometimes even alone it has the same signification. In Vogel's Nosology it is defined a discharge of pure blood from the belly.

CATARRHŒ'CUS, (from *καταρρέω*, to flow from). A word applied to diseases proceeding from distillations of an acrid fluid.

CATARRHO'PA PHY'MATA, (from *καταρρέπω*, to tend downwards, and *φυμάτα*, tubercles). Tubercles tending downwards; or, as Galen says, those that have their apex on a depending part.

CATARRHO'POS NO'SOS, (from *καταρρέπω*, to tend backwards, and *νοσος*, morbus). A remission of the disease, or its decline, opposed to paroxysm.

CATARRHUS, a DEFLUXION, (from *κατα*, and *ρέω*, to flow down). Called also *bronchos*, *catarrheuma*, *fluxio*, *rheuma*, *capitlenium*. It is an inflammation of, or an increased and morbid secretion from, the mucous membrane of the nose, eyes, throat, mouth, or lungs, which, in a slight degree, is called a cold. Dr. Cullen ranks this genus of disease in the class *pyrexia*, and order *profluvia*. He enumerates two species: the first from cold, called also *amphimerina tussiculosa*, *tussis catarrhalis*, *rheuma catarrhale*, *cephalalgia catarrhalis*, *coryza catarrhalis*, *phlegmatorrhagia febricosa*; the second from contagion, called *catarrhus epidemicus*. Hippocrates mentions seven species of defluxions under the appellation of *catarrh*; and, with Cœlius Aurelianus, under this term comprehends *coryza*. Dr. Cullen uses the last as a synonym to catarrhus.

As this is the first disease of importance in which the idea of a defluxion has occurred, we may take the opportunity of making some remarks on an opinion which has, for more than two thousand years, influenced the language of medicine. When, from any cause, a tumour, increased action of, or an increased discharge from, a part, occurred, it was called a defluxion, or rather a *ρευμα*, from *ρεῖν*, *fluo*: in fact, it meant no more than that the vessels contained an over proportion of fluids which were sent to the part. Yet, even in the earliest periods, the word rheum made a fixed impression on the mind, as a peculiar substance; and we had a cold, a hot, a saline, an acrid, and viscid rheum, in almost every complaint. The former editions of this Dictionary repeated this language more often than the pages recurred; and, in cleansing an Augean stable, who can say that every atom of offensive matter is removed? It is necessary, however, in

this place, to observe, that rheum, as a peculiar morbid fluid, has no existence; and that it cannot be, therefore, hot, cold, acrid, saline, or viscid. When an increased action of any part is preceded by fever, it was styled a hot rheum; when fever was the effect, the rheum was cold. If a sore was irritable, the rheum was acrid; if a tumour did not readily suppurate, it was viscid; while every appearance depended on the increased action being an effect or a cause, on the state of the vessels, or on the nature of the organ. We still preserve the term in rheumatism, and, "a græco fonte parce detorta," in catarrh.

In this place we consider only the catarrh attended by fever; whether it affects the nose, the breast, or the fauces, according to the following lines.

*Si fluit ad pectus dicatur Rhēuma CATARRHUS.*

*Ad fauces BRO'NCHUS ad nāres ésto CORY'ZA.*

The seat of the catarrh is in the membrane of the nose, the frontal sinuses, the antra Highmoriana, all the cells of the os sphenoides, the mouth, fauces, eyes, the aspera arteria, and its branches in the lungs. It is most frequent in cold climes, in spring and autumn, or in variable seasons; and is said to be more common with those who have narrow chests, long necks, are disposed to coughs; the phlegmatic and weak.

Its general cause is supposed to be suppressed perspiration; and this so often occurs in our climate, that we can account for every catarrh. It may appear singular to reject this cause; yet, how often is perspiration suppressed without catarrh; how often catarrh occurs without the supposed source. We remember a period, *not* during an epidemic influenza, that in one evening, nearly at the same hour, six persons were seized with violent catarrhs: two of these had not been out of their bed, from a gouty paroxysm, for six weeks; and two others had been confined for many days to their room. The fact, recorded by Martin, of an epidemic catarrh happening at St. Kilda, when the steward went to this remote island to receive the rents, is well known; and we, for many succeeding years, witnessed the fact of a lady who regularly had a cold when she returned from her country to her town house; though servants, for many days, preceded her, fires were made in every room, and her removal was always before Michaelmas. It is common also, on beginning a course of sea bathing, to direct a little delay, lest a cold should occur on the change of air; and though we can more readily account for a person catching an infectious disease, on removing from a healthy to an infectious atmosphere, the contrary is not equally probable, unless some cause should concur to facilitate the action of the miasmata. Yet the latter sometimes happens, and may be owing to a cold. A late author, if we mistake not, a Mr. Kelson, has adduced many arguments to prove this position; and, when we reflect that no epidemic is so universal, so steady in its progress and so constant in its returns, as influenza, we must at least doubt whether catarrh is not more often owing to miasmata than change of temperature. We should indeed doubt whether it were not always owing to the former; but that we know an organ builder constantly affected with a catarrh on tuning an organ: and the connection is general and constant between the discharge from the skin and the lungs; the

defect of one is so often supplied by the excess of the other, that cold must be a very frequent cause.

In the inflammatory CATARRH the symptoms are a redness, heat, soreness and sense of distention in the eyes and eye lids; at the same time there is an unusual secretion of tears, and watery mucus, which, running down the cheeks, inflame them. When the nose is affected there is a sense of stuffing and swelling in the nostrils, an alteration in the voice, a loss of smell: and, if the inflammation runs high, a thin mucus is secreted, which produces heat and soreness of the nostrils, sneezing, and sometimes inflammation, with excoriation of the upper lip. If the throat, trachea, or lungs, are the seat of the disease, the thin mucus separated in these parts inflames them: sometimes a swelling of the nose attends, or perhaps the whole face is puffed; a languor, stupor, deafness, and soreness of the ears, are common complaints. When the throat is affected, the tonsils and parts adjacent are red, sore, and hot, accompanied with a secretion of watery mucus, which stimulates and occasions a constant, troublesome, and tickling cough: sometimes the whole mouth is sore; there are little excoriations on the tongue, and a constant flow of saliva, with a soreness of the salivary glands, and the lips are inflamed and excoriated. When the larynx or trachea is affected, a soreness is felt in them, attended with a hoarseness, and generally with a troublesome tickling cough. In the lungs, this disease produces a soreness, tightness, and sense of fullness in the breast, with a difficulty of breathing, and a violent cough, with which nothing, or only a watery mucus, is at first spit up: the cough produces soreness under the sternum and in the sides, and sometimes head ach, sickness, and retching. All these parts are occasionally affected at once; but more generally it happens that one only is first diseased. The inflammation spreads more or less, as circumstances concur to favour its progress. The inflammation too varies, according to the strength of the patient, or the violence of the attack. In the evening the symptoms are more troublesome; but in the morning a gentle moisture in the skin appears, and the patient is easier. In weakly habits the pulse is frequent, but not very hard; the appetite is lost, and the increase of the evening paroxysm is considerable.

In the less inflammatory kind the secretion of the mucus comes on first, or at least the previous fever is not very easily distinguished. The running from the nose is not watery, but viscid; though thin, and not very stimulating. This mucus, when it is secreted into the throat, produces a cough, by which it is thrown off, and sometimes a nausea; or affecting the lungs, there is a spitting with the cough. This expectoration of phlegm is most considerable after sleep; but there is no great sense of soreness or fullness. After some days inflammatory symptoms come on, though not in a great degree, nor is the whole system often much affected. These symptoms are followed by an increased secretion of mucus, which, becoming viscid, if it was not so at the beginning, loses its stimulus. If the inflammation is great, the mucus discharged is yellowish, and sometimes tinged with blood; as this goes on the other symptoms abate, and at length the discharge by spitting grows whiter, then less in quantity. If the pa-

tient is in a cold atmosphere, the cough is the more troublesome, the other symptoms are aggravated, and the disease is prolonged. If, through an imprudent exposure to the air, a relapse happens, the same course recurs. If the inflammation is very considerable, an angina, or a quinsy, may be produced; or if there is also the inflammatory diathesis, a pneumonia, or other disorders tending to hectic, may occur.

A catarrh consists in an inflammation of the membrane lining the nose, the fauces, and the lungs, called from Schneider, who described it, and who has left us six small, but not thin, quartos, on catarrhal inflammations of this and other mucous membranes. If it does not reach the bronchiæ, it requires little care. Warmth, diluting mucilaginous liquors, slight sudorifics, and gentle laxatives, soon remove it. Should the inflammation reach the bronchial glands, it may be considered as a slight peripneumony, and the remedies for that complaint may be less actively employed. Bleeding is seldom required: the bowels should be kept free, and the pediluvium, breathing the steams of warm water, with a slight opiate at night, are generally sufficient for the cure. An emetic, however, is sometimes, though seldom, necessary. The mucilaginous drinks are supposed to relieve one of the most troublesome attendant symptoms, the cough; nor need we impede the exertions of any old nurse who may strenuously recommend bran or lintseed tea, barley water, or a decoction of coltsfoot. Of course, the saline draughts must be loaded with spermaceti; but if both are omitted, the patient will not essentially suffer.

A catarrh, however, though in itself a slight disease, is often the parent of a very highly dangerous and generally fatal complaint, viz. consumption. The inflammation is communicated to a vomica, and its ulceration brings on hectic. In more advanced life it leads to humoral asthma, or hydrops pectoris. It should not therefore be neglected; but the most simple precautions, except when the disease is of peculiar severity, are only requisite.

*Chronic catarrh* sometimes occurs; but we see nothing to add on this subject that has not been anticipated under the article of HUMORAL ASTHMA, or that will not recur under PERIPNEUMONIA NOTHA. It is, however, often a gouty symptom; and sometimes attends infarctions of the liver, in those who have for a long time lived within the tropics.

CATARRHUS EPIDEMICUS. If a common catarrh be so general in its attack as to excite the suspicion of its arising from some aerial influence, or from contagion, we may with greater reason attribute to either cause the catarrh which is the subject of the present article. The former source was so impressive, that the Italian appellation of *influenza* has, in every language, distinguished it. The original country of this complaint is not known. Hippocrates seems to have been acquainted with it; and since medical records have been kept with accuracy, we find it occasionally appearing in different regions, and travelling, with an equal, uninterrupted pace, in different directions. The universality and the violence of the epidemic catarrh force the disease on our notice: the peculiarity of its symptoms attracts our attention; but we are compelled to read, *ad fastidium usque*, that the head ached at the extremity of Africa as at the North Cape, and that the cough was

equally troublesome on the Danube and on the Thames, on the Ohio and the Rhine. The reason for this accumulation of minute uninteresting description it is not for us to fathom, but we cannot repress a recurrence of the disgust which has so often occasioned the honest anguish and the aching head.

In the chronology of the complaint we need not go further back than the twelfth century, the date of the first record collected by Dr. Cullen, *Nosology*, vol. ii. p. 173. From that time he has traced the disease, in the writings of different authors, with sufficient minuteness. With respect to its course, it seems most frequently to proceed from north to south, but it has been found also to travel from west to east. These, however, are points of curiosity only, and we need not enlarge on them.

The symptoms of the epidemic catarrh differ in some respects from those of the common cold, and were we here to be minute, we should contend that it forms a different species. The attack is remarkably sudden, and at first attended with considerable debility. A few minutes have often interposed between the feelings of high health and extreme weakness. The head, especially the forehead over the eyes, is particularly loaded; all exertion is painful; a tickling of the nose, with frequent and violent sneezing, often suddenly comes on. A load, rather than pain, in the chest, is very troublesome; cough is severe and dry, the tongue parched, thirst often intense. A sore throat is not a common symptom, yet a bright efflorescence is sometimes observed on it. Pulse is low and frequent, seldom hard; the skin constantly dry. In the progress of the complaint, the breast is sometimes more affected, and pleuritic pains are observed in the young and robust. As the skin becomes softer, the tickling acrid mucus from the nose becomes thicker, the head more free; but a considerable debility remains often for several months, and from this period the suppuration of latent tubercles has been often dated.

The middle aged, the strong and robust, are in general soonest affected, and suffer most severely: children and old persons are less violently attacked; yet in the latter it is most often fatal: a humoral asthma, or a catarrhus suffocativus, is a frequent consequence. Children at the breast generally escape, nor did any seem to suffer within the first year; but no period of advanced age, nor any previous disease, appeared to secure any person. All beyond early infancy were indiscriminately attacked. It has very rarely happened that any person who had perfectly recovered was again attacked; but he has appeared equally liable to the influence of a future epidemic.

The causes undoubtedly existed in the atmosphere. Of a dozen persons in perfect health, in the same room, ten have been often attacked within a very short period. Those confined to bed, insulated from every infected person, have equally suffered. In one hospital, containing one hundred and seventy persons, more than one hundred were attacked within twenty-four hours, and few of the remainder escaped. The infection passed the Atlantic, with little or no remission of its severity, and attacked Americans who had not had the slightest intercourse with Europeans.

Is not contagion then also a cause? It evidently is, though in many instances only an exciting cause;

yet the concurrence of the disorder with contagion, apparently received by the most familiar intercourse, has often appeared so striking, that its influence must be admitted. It is indeed difficult to say, when every one is equally exposed to a general cause why any given person should be exempted, whether contagious influence concurs or not. The man most subject to contagion may have been affected, as well as those at a distance from any fomes. The negative cannot be proved; but the very existence of the question seems to show that there were many apparent instances of its influence, though it was often perhaps, as we have said, an exciting cause only. Other exciting causes were cold, fatigue, and depressing passions.

The predisposing causes were previous debility of every kind, in the young and robust. In the aged, infirm health seemed by no means a predisposing cause. The previous state of the air, either with respect to heat, cold, elasticity, or damp, seemed to have little power. Influenzas have recurred at every different season, in every state of the barometer, thermometer, and hygrometer. If we were to fix on any state of the atmosphere in which it has most frequently appeared, we should say it was when supersaturated with moisture.

The distinctions between common and epidemic catarrhs, are the universality of the attack and the violence of the symptoms. Yet in these there are various degrees; and we have seen influenzas where not one in twenty have been affected, and where the appearances scarcely differ from common colds. The load in the head, and particularly over the eyes, with the great debility, more strikingly distinguish this disease, and it bears the same relation to the common catarrh that the putrid pneumonia does to the inflammatory species. Physicians have differed respecting the propriety of bleeding. It may, in the young and strong, be indicated; but it is by no means a general remedy, and should scarcely in any instance be employed. Even in these, however apparent peripneumonic symptoms may seem to indicate it, the practice is followed by considerable, often a long protracted, debility. It is with regret we are obliged to add, that the mania for bleeding is far from being extinguished, and we daily witness its mischief in the putrid forms of diseases, which were usually inflammatory: real inflammatory complaints are now very rare.

Vomiting is a remedy better adapted to the disease; but even this discharge, if violent, greatly debilitates the patient, and it is not easy to set limits to the operation of an emetic. In nauseating doses, combined with opiates, both the ipecacuanha and tartarised antimony are highly useful; but to these we must return.

When the pains in the side, usually indicating bleeding, are violent, a blister is the appropriate remedy; and it is always necessary to keep the bowels free, though the action of violent purgatives greatly debilitates.

In short, in this and every putrid complaint it is necessary to keep up the *vis vitæ*, and gently determine to the skin. *Diapnoë*, a term applied by Chenot, to distinguish this easy perspiration from more violent sweat, will relieve without inducing debility, and this will be best kept up by warm cordial liquids. The use of wine, at first in moderation, and afterwards more freely, is very beneficial; and by thus cautiously supporting the strength, nature will often effect the cure.

The wine should be given with warm water, and the determination to the surface secured by diluting liquors, and a moderately warm room. If this is not easily effected, emetics in nauseating doses, with opium, may be given with success. The neutrals, particularly the ammoniacal ones, will assist this operation; and vinegar whey, with white wine, is also an excellent diaphoretic. Nitre is often injurious by its cooling sedative power, and from its irritating cough. If any particular medicine, not peculiarly suited to these indications, is necessary, we think it is the camphor. It is eminently useful in putrid peripneumony, and we think it has been so in the epidemic catarrh.

Bark has been recommended, and often, it is said, given with advantage. We have had its necessity in frequent contemplation during epidemic catarrhs, but never yet found it necessary. In general, it may be asserted that this disease is never fatal. In its consequences it may be so; and the cutting a corn may induce gangrene, but the operation is not on that account dangerous.

The debility that follows is very considerable, and continues often for many months. A cordial diet, free air, and exercise on horseback, are its best remedies. The author of this article, who suffers always severely from influenza, experienced this debility in a great degree; and though the cough remaining was considerable, he used with the happiest effects the cold bath. The bath was at some distance, and at first both in going and returning he was obliged to rest three times: on the second attempt he rested twice, and on the third once only. On the fourth no rest was required, so rapid was the recovery.

See Hoffman's Med. Rat. Syst. Opuscula Med. Doctoris Baker, Dr. Fordyce's Elements, part. ii. Brooks's Practice of Physic. Schneider de Catarrhis. Cullen's First Lines, vol. ii. p. 83. edit. 4. Wallis's Sydenham.

*CATARRHUS INTESTINORUM.* On considering the affections of the mucous membrane from inflammation, our attention was necessarily attracted by this disease, which, however, has not yet found a place in the medical systems. It appeared, on reflection, singular, that, though the *œsophagus*, at least its upper part, was occasionally affected by catarrh, there was no instance of this disease being continued to the stomach. It however occurs to observation in the intestines; and diarrhœa, from cold, is no uncommon disease. It may be discovered by its occurring in consequence of exposure to cold and damp, by its coming on with fever, with slight colic pains, acrid motions without relief, excoriation of the lower part of the rectum, and the absence of either bilious evacuations or symptoms of indigestion. The cure is sufficiently obvious. But a question here arises; is dysentery nothing more? We must recur to this subject; and what we have here mentioned will not, we trust, be forgotten. The facts just recorded are, however, faithful pictures from nature, without any reference to the connection just mentioned.

*CATARRHUS VESICÆ.* This disease is noticed by Hoffman, Licutand, and Cullen, but by few other authors. It is confounded with dysuria, with calculus, and with abscess of the urinary organs. We have twice seen it as a true catarrhal affection, from cold; and twice *only*. It consists in a painful discharge of urine, sometimes with fever, but more frequently without its

attendance; and of the urine nearly half the bulk is composed of a light, flocculent matter. It appears, though very rarely, as we have said, from cold, but more often from any cause which occasions acrimony of urine, or a difficulty of discharging it; in fact, from any cause which excites inflammation or irritation on the neck of the bladder, or occasions an unusually strong action of this hollow muscle. Its cause will require only an investigation of the previous symptoms, but these will not always assist in determining whether the discharge be not purulent. To the experienced eye pus is soon known by its filamentous appearance, while the mucus of the bladder is more light and uniform. The smell, however, will immediately discover it.

The cure will be regulated by the cause. Mucilaginous diluting drinks, with gentle laxatives, are always proper; and if the pain is violent, opiates may be joined. We seldom want any further aid: but it is sometimes necessary to inject the opiates united with a starch clyster; and we have already observed, that camphor exerts a peculiar sedative effect on the bladder. A mild diet, rest, and a warm room, will greatly expedite the cure of every catarrh.

CATA'RRHUS BELLINSULA'NUS. See CYNANCHE PARODIA.

CATA'RRHUS SUFFOCATI'VUS. See SUFFOCATIO STRIDULA.

CATARTI'SMUS, (from *καταρτίζω*, to make perfect). According to Galen, it is a translation of a bone from a preternatural to its natural situation.

CATASA'RCA, (from *κατα*, and *σαρξ*, caro). See ANASARCA.

CATASCHA'SMOS, (from *κατα*, and *σχαζω*, scarifico). Scarification; and, according to Dioscorides, a deeper scarification than common, which is necessary in gangrene and sphacelus.

CATASTA'GMOS, CATASTALA'GMOS, (from *σταζω*, to distil). These are names which the Greeks, in the time of Celsus, employed for DISTILLATIO.

CATASTA'LTICUM, (from *στελλω*, *καταστελλω*, to restrain). It signifies styptic, astringent, and is sometimes termed *castalticum*.

CATA'TASIS, (from *κατατείνω*, to extend). In Hippocrates, it means the extension of a fractured limb, or a dislocated one, in order to replace it; as well as the actual replacing it in a proper situation.

CATA'XA. Both Aëtius and Actuarius express by this word raw silk, or silk before it is dyed.

CATE'E. See ACAJAIBA.

CA'TE, and CA'TECHU, (from *kate*, a tree, and *chu*, a juice, in the Japanese language). See TERRA JAPONICA.

CATEIA'DION, (from *κατα*, and *εια*, a blade of grass). A long instrument which was introduced into the nostrils, in order to provoke an hæmorrhage in the cure of the head-ach. It is mentioned by Aretæus. It was thus called, either because the instrument had at the end a blade of grass, or was made like a blade of grass for the purpose.

CATELLO'RUM, O'LEUM, (from *catulus*, a whelp). It is olive oil in which young whelps have been boiled until their flesh separates from the bones; after which are added thyme, marjoram, &c. The whole stands together in the sun, and then the oil is strained for use. See PH. PARIS.

CATELLUS CINERE'US: so called from its head being like that of a dog. A CUPEL or TEST. See CUPPELLA.

CATE'VALA. COMMON ALOE. See ALOE HEPATICA.

CATHÆ'RESIS, (from *κατα*, and *αιρω*, to take away). The subtraction of a part of the body by any kind of evacuation, called also *detractio*.

CATHERE'TICA, (from *αιρω*, to take away). Remedies which consume superfluous flesh. See CORRODENTIA.

CATHA'RMA, (from *καθαίρω*, to purge). The excrements purged off from any part of the body.

CATHA'RMOS, (from the same). Purgation by medicines, and the cure of a disorder by superstitious remedies.

CATHA'RSIS, (from the same). A discharge from the uterus, bladder, or intestines, excited either by nature or art.

CATHAR'TICA, (from *καθαίρω*, to purge). This word is generally used as expressive of purging medicines; but it implies emetics in ancient authors also.

In this place, however, we must adopt the common language, and speak of purgatives only; a class of medicines of great variety and singular utility. By pharmaceutical authors, they are divided into lenitives, purgatives, and drastics; and by therapeutical writers, into those that act by increasing the evacuations, in consequence of the stimulus applied to the excretory ducts of the different glands, and those that increase the action of the intestines themselves. There are others that act by exciting a commotion in the system, in consequence of their poisonous nature; and these show deleterious effects, immediately on their introduction, by exciting vomiting. Of this kind are the gutta gamba, the seeds of some species of the croton and jatropa, the tobacco, probably the colocynth, and others. Another division, now almost obsolete, is that into phlegmagogues, cholagogues and hydragogues; purgatives that evacuate phlegm, bile, or water: these very nearly correspond to the lenitives, purgatives, and drastics. With the first, often styled minoratives, eccoprotics have been confounded, but improperly. The last are certainly mild in their operation; but this is not always owing to their moderate stimulus, but often to their want of solubility in the first passages, in consequence of which they act on the rectum only, since they reach that part with little change. Thus sulphur and aloes are eccoprotics, and even the gutta gamba is an ingredient in that recommended by Dr. Fordyce, as the other parts of the formula are not very soluble. We shall therefore follow the pharmaceutical division just mentioned, and then add a few remarks on the eccoprotics.

Lenitives chiefly act by increasing the watery or mucous discharges from the glands, and comprehend all the phlegmagogues of the ancient pharmacutists. The mildest of this class are the vegetables and the acid fruits. Of the vegetable lenitives, the oleraceæ are the principal; and of the acid fruits, the tamarinds, the apples, and the prunes. It is doubtful whether the hesperidæ (oranges and lemons), the senticosæ (strawberries, raspberries, grapes, gooseberries, &c.), are cathartic, except in considerable quantities. They seem to be directed rather to the urinary organs; though in some constitutions,

from idiosyncrasy, probably, they operate as cathartics. All the neutral salts, except the ammoniacal, are in a greater or less degree laxative. To these must be added the supertartrate of the vegetable alkali, viz. the crystals of tartar. The saccharine vegetable substances belong also to the lenitives; as the pulp of the cassia, manna, and, what, with a little latitude, may be referred to the same rank, honey. The vegetable oils are all slightly cathartic; but we use only the olive and the castor oil. Sulphur, from the little change it experiences in the stomach and small intestines, is a cathartic of a similar nature; and to this class phosphorus is added: but, until some safer mode of exhibition is adopted, we would not advise this substance to be employed. The bitters, the gall of animals, the foetid gums, the various balsams, the guaiacum and the myrrh, appear to be occasionally, in a slight but permanent degree, laxative; though not usually arranged in this class. The guaiacum, indeed, is often more active; but this seems frequently to depend rather on idiosyncrasy than a real cathartic power. The foetid gums are excellent vehicles for ecoprotics.

Lenitives, in general, very slightly stimulate the intestines, but seem chiefly to act by increasing the secretions from the glands, whose ducts open into the intestinal canal. They do not increase the heat of the body nor the pulse. They give little uneasiness in the stomach, except from their bulk; and this is chiefly obvious in the saccharine lenitives, and sometimes in the oily. They discharge copious watery fæces; but by no means the substances hardened in the cells of the colon. In many instances, they even lessen heat; and as ecoprotics, unbruised mustard seed, or a clove of garlic, is swallowed, without producing any sensible irritation. The saline lenitives excite thirst; and this may be readily gratified, as warm diluting liquors assist their operation.

*Purgatives* are more active, excite the action of the muscular fibres of the intestines, and are consequently better adapted to remove the more hardened fæces. Of these there is a considerable variety. The leading distinction is, into those which are astringent, or have no such power. The former are preferred, from their strengthening rather than weakening the bowels. They are supposed, however, to leave a disposition to costiveness; but, while the appearance of astringency leads to a suspicion of this effect, we find little foundation for its existence. All the cathartics, except, perhaps, the saline and oily, render the intestines less irritable; since vessels, stimulated to discharge an unusual quantity of fluids in a given time, sink afterwards into a comparatively torpid state; and, indeed, when the circulating mass is drained of any considerable proportion of its fluids, all the secretions are for a time lessened, until the loss is repaired. But while we cannot deny some subsequent astringent effect to rhubarb, for instance, we cannot admit of its strengthening the bowels by the same power. We have found no effect of this kind, and the continuance of small doses has appeared to be only ecoprotic. When the bowels have been weakened by inflammation, or diarrhoea, it has seemed injurious from its acrimony. This, former practitioners tacitly allowed, by toasting it; which they thought increased its astringency, but really only lessened its cathartic effect.

The distinction between lenitives or drastics, and laxatives, is by no means easy; since by diminishing or increasing the dose of the last, they may, with some propriety, be considered as belonging to the first or second class. This inconvenience, however, attends all natural arrangements; but, in our enumeration of the different medicines, we shall follow them very nearly in the order of their activity.

As laxatives, we employ the *sena* (cassia sena); *ipecacuanha* (callicocca ipecacuanha) in decoction; the *polytody root* and *myrobolans* (polypodium vulgare et emblica); the *damask rose leaves* (rosa damascena); *rhubarb* (rheum palmatum); *purging flax* (linum catharticum); *broom* (spartium scoparium); *mechoacanna* (convolvulus mechoacanna); *buckthorn berries* (rhamnus catharticus); *jalap* (convolvulus jalapa); *rattle-snake root* (polygala seneca); *celandine root* (chelidonium majus); *black alder* (rhamnus frangula); *scammony* (convolvulus scammonia); *common and dwarf elder*, *inner bark* (sambucus nigra et ebulus). From the mineral kingdom laxative cathartics are, James's powder, calomel, and phosphat of silver.

These substances act with greater or less acrimony; and those towards the end of the list are often highly acrid. Many others might be enumerated, which are found in the writers on the *Materia Medica*, and which occur in their places in this dictionary. From these before him, however, the practitioner may have a sufficient choice. In general, these laxatives excite colic, and sometimes prove emetic: they frequently stimulate the system, increase the heat and the pulse; but, on the other hand, they are active and effectual evacuates. If an opiate has previously produced some relaxation in the cells of the colon, they will bring away the most hardened, long retained scybala. In cases of fever, however, these are often only evacuated when the relaxation is produced by the solution of the disease. Mild purgatives will, in those cases, discharge what had escaped the action of the most violent. The former part of this list contains the chologogues of the ancients.

The drastics are the *gamboge* (stalagmitis of Kœnig); *wild cucumber* (momordica elaterium); *bitter cucumber* (cucumis colocynthis); *black and white hellebore* (helleborus niger, and veratrum album); *sea colewort* (brassica marina, soldanella pharmaceut.); resin of jalap, nitrat of silver, and various mercurials and antimonials, q. v.

These drastics act with great violence, generally disorder the stomach and the whole system in a considerable degree, and sometimes inflame the intestines. These, and some of the more active medicines of the former group, were chiefly used by the ancients, for the milder laxatives were introduced by the Arabians, and occasioned the numerous cautions respecting the use of purgative medicines. From this circumstance also, and from the use of mercurials as laxatives, the supposed necessity of confinement to a warm room apparently arose. This measure may be dictated by convenience; but certainly warm air, and a horizontal posture, retard or lessen the operation of laxatives.

The narcotic cathartics remain, which disorder the senses, produce stupefaction, and seem to act as cathartics, by the general commotion that they produce. We think these effects in some measure follow the use of the gutta gamba, the colocynth, the hellebores, and

some of the other drastics, when first introduced into the stomach. They often occasion sickness, faintness, and cold sweats; but the cathartics more decidedly sedative are the *tobacco* (*nicotiana tabacum*), the *foxglove* (*digitalis purpurea*), and the *lactuca virosa*. One effect of the drastics, which we deferred mentioning till we had introduced this last group, is the discharge of water from the cavity of the peritoneum, the chest, and the cellular substance. This effect seems to arise from the sedative power of the remedies. In this moment of total relaxation every bond of union is removed, even the inosculation of the maternal and foetal parts of the placenta, every form of obstruction recedes: the secretory organs yield, not from the action of the remedy increasing the excitement, but from the temporary solution of the tonic power.

We have little to add to what we have already said of eccoprotics. A mild vegetable diet is the safest and the best. Aloes, combined either with the foetid gums or soap, is highly useful, chiefly from its very slow decomposition in the small intestines. Sulphur is equally convenient, from the same cause. The sea water and the purging mineral waters are also highly useful, when they can be conveniently taken. Rhubarb we have found too irritating, unless combined with soap; and a sufficient quantity of the latter renders the bulk inconvenient. We have generally added a small proportion of the scammony, to render it more active. Aloes is by far more useful; and though it sometimes produces piles, yet, in the forms above mentioned, we have not experienced this inconvenience. Dr. Fordyce, in an excellent paper "on the combination of medicines," recommends a compound eccoprotic, which he thinks of superior efficacy to any other. It consists of five parts of aloes, three of sagapenum, two of gamboge, and one of distilled oil of camomile. Two parts of gum arabic are employed to give it a consistence, and the whole is made into a mass with the *syrupus à spina cervina*. From six to ten grains are a dose; and it is said to operate without sickness or griping. We shall resume this subject under the article of COMBINATION OF MEDICINES, and shall then speak of the advantages derived from the union of different purgatives.

One other class of purgatives remains, viz. what are styled, by some late authors, "the mechanical;" consisting chiefly of watery liquors. These act by their bulk, which is the chief stimulus of every hollow muscle. The utility of a large bulk of fluids is particularly conspicuous in clysters, where a pint and a half of milk and water will procure a motion, often more readily than the most active purgative administered in the same manner. We speak, however, of these mechanical cathartics, chiefly to notice the effects of dilution in increasing the power of the neutral salts. If an ounce is the proper dose in two ounces of water, two thirds will be sufficient in half a pint; and perhaps one half in a pint. This fact, before alluded to, solves the difficulty felt in accounting for the purgative power of some mineral waters, in which the proportion of salts is inconsiderable.

In describing the effects and the use of cathartics, instead of explaining them in the way of some therapeutical authors, *a capite ad calcem*, we shall first speak of their more immediate effects; and, from them,

trace the more remote and distant. We shall afterwards enumerate those diseases in which they are chiefly indicated, and in which they are most essentially useful.

The first and most obvious effect of purgatives is the discharge of the contents of the abdomen. The intestines are subject to various accumulations of hardened faeces, undigested matter, or inspissated mucus. These substances impede not only the passage of the fresh nutriment, but prevent the absorption of the newly-formed chyle, and occasion general languor and debility. Laxatives, as we have said, also stimulate the orifices of the excretory ducts, and promote the circulation through the vessels of the glands. This is a very important effect, and renders these medicines useful in a variety of complaints.

By the evacuation of the contents of the intestines, it may be supposed that cathartics would relieve the stomach, and promote, in every instance, the discharge of its contents: but this effect is not constantly produced; and where a viscid mucus has accumulated, its weight carries it to the bottom of the larger curvature of that organ, and it is rarely discharged without the assistance of an emetic. The complaints of the stomach, supposed to be relieved by cathartics, are more often accumulations in the duodenum.

When the intestines are loaded, and particularly the small intestines, some pressure is made on the descending aorta, and the blood is determined in larger proportions to the ascending branches, occasioning pain in the head, languor, and general uneasiness. These symptoms cathartics commonly relieve; and, by taking off the pressure from the descending aorta, facilitating the circulation through the glands of the chylopoietic viscera, and thus increasing the circulation in its branches, cathartics become the most useful remedies in diseases of the head.

The efficacy of cathartics as evacuants of particular fluids, which seem chiefly to depend on the solubility of the medicine, merits our attention. The saline and other lenitives act immediately on passing into the intestinal canal, and stimulate not only the excretories of the liver and pancreas, but of the mucous glands in the neighbourhood; and it is this class of cathartics on which we chiefly depend for the evacuation of bile. By some accident, rhubarb has been considered as the chief evacuant of this secreted fluid; but we have never found it peculiarly adapted for this indication, except when combined with soap. Indeed the stimulus of rhubarb on the internal surface of the canal is so considerable, that even when it has passed the entrance of the ductus communis, the irritation may be communicated to it. Irritation is always readily conveyed along the surface of mucous membranes; for we find a stone in the pelvis of the kidney sometimes convey a peculiar sensation at the extremity of the glans penis.

The active cathartics alone stimulate sufficiently the muscular fibres of the colon; so as to evacuate the contents of its cells: and for this purpose calomel is the most effectual. Jalap, a medicine of considerable utility, seems also to combine a power of assisting the watery secretions; and thus becomes a serviceable addition to the lenitives, when employed with this view. Rhubarb seems also particularly useful in evacuating

the contents of the larger intestines. On the rectum, sulphur and aloes seem to act exclusively; and the one is supposed to relieve, as the other is to induce, the hæmorrhoids. The evacuation of the contents of the rectum is, however, in general, more properly trusted to clysters. The importance of this discharge is considerable in relieving any inflammatory diseases of the uterus or vesica urinaria; and, as injections reach so nearly the affected part, opiates are thus advantageously administered. But this is from our present subject.

The diseases in which cathartics are advantageously employed are numerous. We have detailed the advantages arising from the evacuation of the contents of the bowels; and it will be obvious, that, in every case of dyspepsia, of bilious accumulations, and worms, they must be of essential utility. For the discharge of worms, and the mucus which forms their nidus, the most stimulating cathartics are requisite. For dyspepsia the eccoprotics; and for bilious accumulations the laxatives, and of these rhubarb and calomel, are the most useful.

The infarctions of the different viscera require the constant use of cathartics; since, from the steady and frequently repeated stimulus to their excretories, we promote a more active circulation through their substance. Dissection discovers various indurations in different organs, whose excretories open into the abdomen; but we can distinctly ascertain the existence of one only during life, viz. infarctions of the liver. The small doses of calomel, which give a general activity to the circulation, are greatly assisted by the regularly repeated stimulus of gentle laxatives; and, indeed, without these, would be of little service. When no symptom leads to the suspicion of disease in any one organ, a general cachectic habit renders laxatives almost indispensable: indeed, in every instance of this kind they are highly useful. When the mesenteric glands are affected, we can scarcely style the lacteals their excretory ducts; yet the stimulus of cathartics on their orifices is highly useful. We shall find reason to conclude, that all the infarctions of conglobate glands are owing to a want of irritability in these vessels; and the disease is not only relieved by the stimulus of the cathartic, but probably by the absorption of those found to be most useful, viz. sea water, and the purging mineral waters. The latter are frequently the most effectual also in infarctions of the liver; and, when joined with a chalybeate, which, as we have said, is supposed to prevent the debilitating effects of purging, have been greatly celebrated. Cheltenham water is the most fashionable of this kind.

In diseases of the head, from the effects of cathartics just mentioned, we may expect the greatest advantages; and we find from experience, that they chiefly relieve every accumulation on the cerebrum. In every case of *apoplexy*, *carus*, and *lethargy*, cathartics are remedies of peculiar utility; and, in the course of our labours, we shall find many diseases connected with such accumulations that have not been suspected to originate from this source.

The great utility of cathartics is, however, conspicuous in febrile diseases. We cannot explain the foundation of the advantages derived from them at present; but can only observe, that in every fever the balance of

the circulation is apparently destroyed; that in some cases the liver, in others the head, often both organs, suffer from accumulation. Cathartics relieve both; and, in checking fever on its first formation, seem to be the most useful remedies. Emetics have had the chief credit in destroying fever in the bud; but, unless succeeded by, or accompanied with, laxatives, they have failed, or performed their office imperfectly. During the whole course of febrile diseases, a regular, and very often an active, discharge from the bowels is necessary: and stools, so far from weakening, add to the strength of the patient. Care, however, must be taken that the discharges be actually feculent. We have known the motions numerous without relief: they have been found only mucous evacuations from the rectum. They have been reported to be copious; but, on examination, have appeared to be only water scarcely coloured. Even when motions have appeared most decidedly feculent at the conclusion of the fever, some matter has been seemingly retained; since discharges of peculiar fœtor and putridity have accompanied or followed the crisis. On this account the lenitives, though often recommended, have not appeared to us the best form of cathartics in *this country*. In warmer climates, where the bile is highly acrid and stimulating, lenitives only are admissible; since laxatives would add to a stimulus already in excess. We now make this distinction, but would subjoin a caution in the words of Baglivi, when he apologizes for a practice which might be suitable only in his own situation: "*Romæ ago et Romano in aere.*"

It may be asked, are laxatives so peculiarly useful in every epidemic? We dare not say so; for we have found some truly asthenic fevers in which they have appeared to have effects highly debilitating. The instances have, however, been very few; and, in general, on the appearance of every epidemic, the practitioner must cautiously examine its nature in every point. He will, however, err most seldom in examining the effects of laxatives if he tries them to some extent. He can soon check his career; and, in the very earliest stages, they scarcely ever are injurious. We must, however, in a future article, point out the fevers which are less adapted to this remedy.

To pursue the particular kinds of fevers in which cathartics are most useful, we must first remark that bilious accumulations are particularly conspicuous in *intermittents*; and from hence arose the anxiety of former physicians to bring the fever to a regular intermission, previous to the exhibition of the bark. In fact, the end really attained was, by previous evacuations, to prevent accumulations in the liver, which the bark might still further impact; nor have we a doubt that the accusation, formerly brought against this remedy, of its producing the tumours styled ague cakes, may have had some foundation. It has been alleged, that these tumours were more common before the introduction of the bark than since. This, indeed, we believe; but the cause was the long continuation of the disease without the use of any active remedy.

In *remittents*, diseases of a similar nature, the same remedy is useful; and of *continued fevers*, it is chiefly employed in the *inflammatory fever*, to cool by the discharge from the exhibition of lenitives; and in *bilious*

fevers, to clear the liver from the accumulations with which that organ is oppressed. In the more common *epidemics*, styled *putrid*, or *nervous*, there appear to be accumulations in the liver and the head. We are told by medical authors to prevent costiveness; but we have only succeeded when we have carried the evacuation further. On these subjects we must again enlarge.

In the *topical inflammations*, cathartics are less generally useful. In *phrenitis*, indeed, they are essential remedies; but, in *pneumonia*, often injurious. In *angina* they are not singularly beneficial; and, in *gastritis*, often inadmissible. In *enteritis* they are of the greatest importance; and, on their management in this disease, the cure almost wholly depends. In *nephritis* and *peritonitis*, lenitives are remedies of importance; and, in *cystitis*, laxative clysters are highly useful.

In the *exanthemata*, also, laxatives are employed with much discrimination. The bowels and skin, as we have said, alternate in their discharge; and, *cutis siccatas*, *alvi laxitas*, is an axiom two thousand years old. By purging, therefore, we may always moderate a cutaneous eruption; we may sometimes prevent it: and, whenever previous fever threatens a copious eruption of *small pox*, next to cool air, active laxatives are the most effectual remedies. In *measles* we have found nothing prevent so effectually the peripneumonic symptoms as a loose belly: and, from one instance, have suspected that purging may be carried to a greater degree than has yet been practised. The child was tender and delicate, with apprehension of weak lungs; the peripneumonic symptoms violent. The cathartics were urged with unusual activity; the disease was mitigated, and the recovery unusually rapid. The instance is, however, a single one. In *erysipelas* and *scarlatina* we know not that cathartics have been urged, or that they have been urged with success. In *gout* we have said they are injurious: in *rheumatism* they are inconvenient. Yet we have thought the doses of calomel, in an active form, have been useful as laxatives.

In *hæmorrhages of the brain* the most active laxatives are useful; but here their benefits seem in this order to end: in the other hæmorrhages, the mildest lenitives only are employed with advantage, to cool rather than to evacuate.

In various diseases, arranged by Dr. Cullen under the class *neuroses*, laxatives are highly useful. In all *comata*, even though not febrile, they are essential. In the *spasmi* they are apparently less beneficial; but, in warm countries, these often arise from acrid bile, and the *trismus infantum* is well known to be owing to this cause. The *chorea*, too, as we shall soon find, is greatly benefited, often effectually cured, by active cathartics. In *colic*, *cholera*, and *diarrhæa*, laxatives are appropriate remedies; but particularly useful in the first: in the two last the discharge requires only to be regulated, sometimes to be rendered more effectual.

In the whole of the class *vesaniæ*, cathartics in different forms and degrees are necessary; and, in the cachexics, particularly in *tabes mesenterica*, we have already remarked their utility. On the subject of *dropsy* we have nothing to add to the observations under the articles *ASCITES* and *ANASARCA*, q. v.

The manuscript of the foregoing article was sent to the printer before we had an opportunity of perusing

Dr. Hamilton's "Observations on the Utility and Administration of Purgative Medicines." It gave us great pleasure to see this confirmation of our opinions, drawn also from the sick bed, by a gentleman with whom we were *once* personally acquainted, and whose abilities we highly respected. He recommends purgatives in chlorosis, chorea, chronic diseases, hæmatemesis, marasmus, scarlatina, and typhus. Under the separate respective articles we shall more particularly attend to his observations: our opinions, in general, are before the reader.

With scarlatina, he speaks of its frequent concomitant, the ulcerated sore throat. The peculiar disease which we have described under the article *ANGINA GANGRENOZA* is scarcely, if at all, known in Edinburgh; at least, in the course of five years, we never saw it: and, in the lectures of Dr. Cullen and Dr. Gregory, this kind of sore throat was spoken of so indiscriminately, as if they were little acquainted with the complaint. In the ulcerated throat as it appears in England, purgatives are certainly not admissible; and we have seldom found them very advantageous in scarlatina. Dr. Hamilton means by purgatives what we have called laxatives, but administers them in separate doses.

**CATHARTICUS**, SAL, (from *καθαίρω*, to purge). Called also *amarus sal*, *magnesia vitriolata*, *Ebshamensis*, and *Epsomensis sal*. PURGING SALT, EPSOM SALT, and ENGLISH SALT. This salt was first obtained from the mineral water at Epsom: it was afterwards separated from the brine which remains after the crystallization of common salt, and the latter is now in general use. It is composed of the vitriolic acid and magnesia; differing from the *natron vitriolatum*, which has a mineral alkaline salt for its basis. The first is often sold for the latter; but they are distinguished by adding any alkaline salt to a solution of the former, when the earth will be precipitated.

It is with this salt that the purging mineral waters are frequently impregnated, and to which they often owe their virtue. It hath a bitter taste, is soluble in less than twice its weight of water, shoots into long prismatic crystals, liquifies and bubbles in a moderate heat, emitting a quantity of aqueous vapours; it changes to a white spongy mass, which is more bitter than the original salt.

If this salt is dissolved in water and crystallized afresh, it concretes into a larger kind of crystals, which resemble the purging salt usually called Glauber's. It has a nauseous bitter taste; is a gentle purgative, operating in general with ease and safety, yet with a sufficient efficacy, and quickly finishing its operation. Two or three drachms, dissolved in a pint of water, operate more powerfully and easily than a larger quantity in three or four ounces. Its passing off hastily, and not exciting the action of the intestinal fibres, seem to be its principal imperfections. In small doses often repeated it promotes the secretions in general, and proves an excellent aperient in many chronic disorders. It seldom occasions gripes or sickness, like resinous purges. If the patient keep warm, small doses will excite perspiration; if cool, they pass off by urine. As a purge, from an ounce to an ounce and a half is a full dose, which, when dissolved in a quart of water with a drachm of mace or of cardamom seeds previously

infused in it, sits easy on the stomach. See Lewis's Mat. Med. Neumann's Chem. Works.

CATHA'RTICUS HISPANICUS SAL. It is produced near Madrid from some springs: it is neutral, and agrees with the natron vitriolatum, or Glauber's salt. Its operation is very gentle.

CATHA'RTICUS GLAUBE'RI SAL. See GLAUBERI SAL.

CATHE'DRA, (from καθίζωμαι, *to sit*). See ANUS.

CATHI'ESTECOS. See DIÆTA.

CATHETERISMUS, (from καθέτης, *catheterus*). The introduction of the catheter into the bladder; an appellation given by P. Ægineta to this operation, which is required in the following cases.

1. When a stone lies internally on the neck of the bladder, and stops the discharge of the urine.

2. When a preternatural weakness of the bladder hinders the urine from being discharged in the usual manner; and when other remedies fail, which often happens in women weakened with labour, or when the head of the child presses on the urethra.

3. When, by long retention of urine, the bladder is so distended and weakened as not to be able to discharge its contents.

4. When mucus, blood, pus, or other matter, sticks in the neck of the bladder, from ulcers, or wounds of the kidneys, or from discharges of bloody urine.

5. When the urethra, or the neck of the bladder, is contracted or obstructed; but in this case bougies are preferred; or when the prostate is scirrhus and prevents the passage of the urine.

6. In the last months of pregnancy it is sometimes useful to introduce the *catheter*, to draw off the urine, as the weight of the uterus obstructs its discharge.

7. When a prolapsus uteri produces an ischury.

8. When a liquor is to be injected into the bladder; in which case a bladder, or an elastic bottle, may be filled with the liquor to be injected, fastened to the catheter, and, by gentle pressure, conveyed through it.

It is easy to introduce the catheter into the female bladder, since the direction of the urethra is nearly straight; but in males there is some difficulty. Heister directs the man to lie on his back, and the operator to take the penis in his left hand, as he stands on the patient's left side, reclining the penis towards the navel; then he is to introduce the catheter, with its concave part to the belly, into the urethra, so far as the os pubis; and so thrusting it under the symphysis of those bones, and moving the hands gently outwards, forces it into the bladder.

If the catheter is too small, it is the more apt to stop in the corrugations and foldings of the urethra, which often occur in elderly men. Dr. Hunter adds, that some impediments are often met with at the caput gallinaginis, in which case he advises to draw the catheter a little back, and press the end of the catheter a little higher, and then it will slip in; but he cautions against using any force. If a difficulty is still found, he advises the operator to put a finger into the anus, at the same time draw the perinæum forward, and therewith endeavour to assist the catheter in its introduction.

Mr. Ware, in a paper expressly written on this subject, says, "The mode in which I pass the instrument is as follows: being first thoroughly oiled, I introduce

it into the urethra, with its convex part uppermost, and carry it as far as it will pass without using force; then I turn it *slowly* round, so as to bring its concave side uppermost; and in doing this, I make a large sweep with the handle of the instrument, and at the same time keep my attention fixed steadily on its apex, or inner termination, which I take particular care neither to retract, nor to remove from its first line of direction. When the catheter is turned, it must still be pressed onward, and its handle at the same time gently depressed: by this method it will be made to enter the bladder."

The catheter made use of by Mr. Ware is twelve inches long, which is more than an inch above the ordinary length; and the curvature larger than common, as represented in the plate he has annexed; and with which he has succeeded often, where others of a different size and curvature had failed.

Those catheters are the best that are made with small holes at their ends, instead of long rhomboidal apertures.

In the following cases this instrument cannot be used:

1. When the neck of the bladder is greatly inflamed, for then the urethra is much contracted, and force in this case would endanger a sphacelus. 2. When a caruncle, cicatrix, or hard tubercle, obstructs the passage. 3. In old men, sometimes from the stricture shrinking, or from wrinkles in the urethra. 4. From the distention of the spongy substance of the urethra with blood. 5. From a scirrhus or preternatural tumour of the prostate gland. 6. From a stone lodged in the neck of the bladder. 7. When the uterus is remarkably prominent and pendulous over the ossa pubis, the neck of the bladder, then forming an angle with the body of the bladder, hinders the passage of the catheter. 8. When the uterus is retroverted, in which state it drags the bladder upwards and backwards.

CATHETERUS. CA'THETER, (from καθίπτω, *to thrust into*). Also called *auliscos*, *fistulā*. It is a long crooked tube introduced through the urethra into the bladder, when solid for the discovery of a stone, or when hollow to occasion a flow of urine if suppressed. The Latins call it *fistula*: and it had the epithet *ænea* from the matter of which it was formed. It is the name also for BOUGIE, which see.

CATHIDRU'SIS, (from καθιδρύω, *to place together*). See FRACTURA and CATIMIA.

CATHI'MIA. In the Spagyric language signifies subterraneous mineral veins; concretions in the furnace of gold and silver; and soot that adheres to the walls in burning brass. It is, in fact, *cadmia* disguised by bad spelling. See LITHARGYRUM.

CATHO'LCEUS, (from καλᾶ, and ἐλκεω, *to draw over*). An oblong fillet which came over the whole bandage of the head, called *periscepastrum*, or the sling with six heads. See FASCIA.

CATHO'LICON. A general or universal medicine, formerly supposed to purge off all bad humours, (from κατα, *through*, and ὅλον, *the whole*): sometimes termed *diacatholicon*, or the universal purge. It was an electuary which Nicolaus prescribed, as a purge suited to carry off all kinds of humours.

CATHY'PNIA, from ὑπνός, *sleep*). A profound sleep.

CA'TIAS, CA'TIUS, (from καθίμι, *dimitto, to place in*). An incision knife, formerly used to extract a dead fœtus, and for opening an abscess in the uterus.

CAT'ILLIA. The weight of nine ounces.

CA'TINUM ALU'MEN. See CLAVELLATI CINERES.

CATI'SCHON, (from κατισχω, *to retain*). One who is costive, or not easily purged.

CATIXIS, (from καίξις, *per rectam viam*). ON THE SAME SIDE. In inflammation of the liver, a crisis of blood is discharged from the nose by the right nostril; and in inflammation of the spleen by the left. It hath long been supposed that nature endeavours with more vigour, and more certain success, to free herself by passages on the side of the disease.

CATOCATHARTICA, (from κατα, *downwards*, and καθαίρω, *purgo*). See CATHARTICA.

CA'TOCHE, and CATOCHUS, (from καίχω, *to detain*). See CATALEPSIS, CAROS, and TETANUS.

CATOCHI'TES, (from καίχω, *to retain*). A stone found in Corsica, which Pliny says attracts and retains the hand when laid upon it.

CATO'DON, (from κατα, *below*, and οδός, *a tooth*; because it has teeth only in its lower jaw). See CETE ADMIRABILE.

CATOMI'SMOS, (from κατα, *under*, and ὤμος, *the shoulder*). By this word P. Ægineta expresses a mode of reducing a luxated humerus, performed by a strong man taking the patient's arm and laying it over his shoulder, so that he can raise him from the ground; thus by the weight of the body the luxation is reduced.

CATO'PTER, (from κατα, *through*, ὁρῶμαι, *to see*, and by metaphor, *to probe*). See SPECULUM.

CATORCHI'TES, (from κατα, and ὄρχις, *orchis*). A sort of wine in which the orchis root has been used. Dioscorides.

CATORE'TICA, CATOTE'RICA, (from κατο, *downwards*, and ῥεω, *to flow*). See PURGANTIA.

CATTARIA. See MENTHA CATARIA, and CATTARIA.

CATTU-SCHI'RAGAM. (Indian.) The Malabar name for the *scabiosa Indica arborea*, the seeds of which kill worms. Raii Hist.

CATULO'TICA, (from καίλω, *to cicatrise*), improperly *catolotica*. Medicines that cicatrise wounds.

CA'TULUS. In zoology it is a PUPPY. See CANIS. In botany it is a CATKIN. See AMENTACEI FLORES.

CATU-TRI'PALI. See PIPER LONGUM.

CAU'CALIS, (from καυκίον, *a cusp*, so named from the shape of its flower). BASTARD PARSLEY, called also *echinophora tertia*, *lahtula Canaria*, *pseudoselinum*, *anthriscus*, *daucus annuus minor*, HEDGE PARSLEY. It has generally red flowers, and possesses the common qualities of the garden parsley. See APIUM HOR-TENSE.

CAUCALOI'DES, (from καυκαλός, and εἶδος, *likeness*). A name of the *patella*, in Moschion de Morb. Mulieb. so called from its likeness to the flower of the caucalis.

CAU'DA. Ætius, in his Tetrab. 4. serm. 4. ch. 103. says, that in some women a fleshy substance arises from the os uteri, and fills the vagina. Sometimes it protuberates without the lips of the pudenda, like the tail of some animal. If this substance ever existed, it must have been enlarged clitoris, or, if a disease, a polypus.

In order to extirpate it, he advises to extend it with a forceps, and then cut it off; after which it must be dressed with lint dipped in rough wine. It is also a name of the *os coccygis*.

CAU'DA EQUI'NA. In anatomy the medulla spinalis ends about the first or second lumbar vertebræ, and there forms itself into many branches, which receive all together the name *cauda equina*, from being like a horse's tail. From the loins downwards the holes in the vertebræ are somewhat lower than the origin of the nerves that pass through them; hence it is of importance, when any disorder arises from an injury of any of the nerves below the first and second lumbar vertebræ, to advert to this circumstance; and, as at the first or second vertebræ of the loins the *cauda equina* begins, so, in tracing the source of all the nerves below these parts, this is their origin. See LUMBARES.

CAU'DA MURIS. A species of RANUNCULUS. See also MYOSURUS.

CAU'DA PORCI'NA. See PEUCEDANUM.

CAU'DA VU'LPI'S RUBICU'NDI. A preparation of lead.

CAUDA'TIO, (from cauda, *a tail*), an elongation of the clitoris. See CAUDA.

CAUDE'X. THE TRUNK of a TREE, or that part of a plant which lies betwixt the root and the branches. According to Linnæus, when a seed germinates, the *caudex descendens* terminates in roots, the *ascendens* in branches and leaves.

CAULE'DON, (because it breaks like καυλός, *a stalk*). A species of fracture, when the bone is broken transversely so as not to cohere.

CAULI'AS, (from καυλός, *a stalk*). An epithet for that juice of the asafetida plant which flows from the stalk, by way of distinction from that which flows from the root, and is called ῥίζιας, *rizias*. Its stalk is styled *caulos*.

CAULIS, and CAU'LOS, (from kalah, a Chaldean term). THE STALK. See CAUDE'X. It is a name also for both the PENIS and VAGINA; and in corn and grass it is called the BLADE. It is a name for a cabbage or colewort. See BRASSICA SATIVA.

CAULIS FLO'RIDA. See CAULIFLOWER.

CAULO'DES, (from καυλός, *cabbage*). See BRASSICA.

CAU'MA, (from καίω, *to burn*). The heat of the atmosphere; or of the body in a fever.

CAU'NGA. See ARECA.

CAU'SA. (Latin.) A CAUSE. Causation, among metaphysicians and logicians, is a subject of peculiar difficulty and of some danger; since, in pursuing the reasoning without due attention, some of the best men have advanced nearer the confines of infidelity than they have suspected; and mankind, ever prone to censure, have caught with eagerness at little errors, and pursued the author with the acrimony which crimes only merited. As logical disquisitions can have no place in this work, we shall fortunately escape the quicksands, though we may encounter whirlpools, on the opposite shore. Dr. Wallis, in his work on Health and Diseases, and in the last edition of this Dictionary, seemed to plume himself on establishing certainty from his disquisitions on this subject, in a science formerly conjectural; yet a more confused farrago of reasoning, with scarcely a clear determinate idea, never

occurred. Disputes, however, are still less within our province, and particularly with our predecessors.

To ascertain the nature and degree of causation respecting diseases, we must first enquire what a disease is; and we shall so far anticipate that article by saying, that a disease is that condition of the human body, in which the actions of life and health proper to it are not performed, or performed imperfectly. According to this definition, the disease consists in the disordered or impeded functions; and these form, in our views, its essence. By these it is defined; by these distinguished. Authors formerly, and often at present, suppose that the disease consists in the injury which disorders or impedes the functions: thus what they consider as the disease is, strictly speaking, only the immediate cause. The difference is, indeed, merely verbal; and, when established, either plan may with equal reason be supported. If, however, it be necessary to speak of diseases as characterised by fixed indisputed marks, it must be established on a securer basis than the fluctuating systems of pathology. In this way the real disease, like the unknown quantity of the algebraist, is uncertain; but as it has distinguishing properties and a peculiar appellation, every end is attained.

Since a disease supposes a change of the body from a sound state discriminated by a given concurrence of symptoms, these symptoms are the effect of that change; and the change itself the effect of a given power by whose influence it exists. Whatever, then, it be by whose influence the disease exists, is its cause. In medicine, also, it is not necessary that the cause be active, though logicians scarcely admit any other: privation, as will be seen, is a frequent cause of corporeal changes, and often a source of disease; as depriving a muscle of a portion of its nervous power, occasions violent convulsions.

The minute difference of causes in the works of many pathologists, would lead to pompous trifling, and would disgrace a science which should be distinguished by its utility alone. The first important distinction of causes is into *internal* and *external*. The former implies some defect previously rooted in the body before it breaks out into a disease, or before it becomes conspicuous by evident symptoms. To such a state, though really a morbid change, Gaubius himself, who considers what we would style the immediate cause as the disease, will not allow that appellation. External causes are, improper diet, inclement weather, sudden changes of temperature, or, indeed, whatever affects the body from without. These have been styled *evident causes*; and even the most empirical systems admit the utility of enquiries into them. Internal causes form the *seminium morbi*, the predisposition to disease; and such is the state of the human frame, that no constitution can be pronounced free from predisposition. There is, in every one, some weak organ which requires only an exciting cause to blow the spark into a flame. Thus a vomica is brought to a suppuration by an accidental cold, which would never otherwise have occasioned any inconvenience. This internal cause, which is often styled *causa προηγουμένη*, or predisponent, is roused to action by what is styled the exciting cause, *causa προεγερτική*, sometimes *occasio*, or occasional cause. This is generally external, though not necessarily so, as we shall soon find. In general, neither of these

causes alone will produce a disease, but the concurrence of both is required. If there is no predisposition, the occasional cause is harmless: without the *occasio*, a predisposition may exist for years harmless.

These causes have been styled, in conjunction, *principia morborum*, and the logical meaning of *principium* may be understood from Sauvages' Definition of a Cause, adopted, if we recollect rightly, from Wolfius; "*Causa est, illud ex quo intelligitur alterius actualis existentia, unde discrepat a principio, ex quo non actualitas sed tantum possibilitas intelligitur.*"

What authors have styled the disease, or what the more correct pathologists of the present day call the proximate cause, viz. the morbid læsion, alone merits the appellation of a cause. "That only," observes Gaubius, "deserves the name of a physical cause, which so constitutes the disease that, when present, the disease exists; while it remains, the disease remains; when changed or removed, the disease is equally altered or destroyed." The lax use of the term *cause* among physicians has occasioned much ridicule on the art, which should have been directed against its unskilful professors: and causes, without effects; effects without causes; opposite effects from the same cause; or the same effect from opposite causes; have not been uncommonly assigned, and furnished a foundation for numerous sneers. The English reader need not look further for examples than Tristram Shandy and Hudibras.

We have spoken of the body only, without mentioning the mind. We well know their mutual influence; but have yet to learn, whether disease may consist merely in mental injury, or, indeed, whether morbid motions can originate from mind. The mental principle, which regulates the whole system, has been already spoken of. Its tranquillity and passions may be considered, as its health and diseases. These, however, are transitory, but they affect for a time the body. Joy and exultation have raised the mental powers so high that they have sunk from exhausted excitability; and the depressing passions, by lowering the irritability, have produced visceral obstructions, and every symptom of cachexy. But whatever may have been the mental source, the effect is continued from disease of body. The mental disease may be alleviated or removed; the bodily remains; nor in any instance, whatever temporary relief may arise from soothing consolation, can the disease be removed without bodily remedies.

In body, however, as in mind, the remote causes may cease to act without any change in the disease. When it is once produced, their presence or absence occasions little alteration. A person, for instance, affected by fever from marsh miasmata, may be removed to the healthiest situation without any change of his complaint; and the cold that produced rheumatism may be removed with little relief of his disorder. This, as we have said, is not the case with the proximate cause: it commences, continues, and ends, with the disease.

Another circumstance respecting causes demands our attention. We have explained two kinds of remote causes; but between these and the proximate there are many intermediate steps. There is, as we have formerly said, a series of causes and effects before the morbid læsion takes place. Thus, in the common cause of dropsy ebriety, we see that the tone of the stomach is originally destroyed. This want of irrita-

bility is communicated to the liver; infarctions take place; the returning blood to the vena portæ is checked in its progress; the exhalant arteries have more than their proportion of fluids; and exhalation is increased beyond what the absorbents can convey, which also seem to experience the same defective irritability. In this series there is no predisponent cause; and which is the remote cause of the disease, the diminished tone of the stomach, the infarctions of the liver, the obstruction of the vena portæ, or increased exhalation? Yet medical authors give with confidence remote and proximate causes, though the former are often various, and the latter frequently unknown. In short, in every science there is too much jargon, and too many pretensions to a knowledge that we cannot, which probably we never shall, possess.

We just now cited the cause of dropsy with a particular design: it was to adduce it as an instance, that predisponent causes, *seminia morbi*, do not always occur. The same occasional causes will produce the disease in the best constitution; as a fall from a house will bring on hæmoptoe in the person whose lungs are most sound.

To return, then; the proximate, or the continent, cause merits our chief regard, as it alone furnishes indications of cure. This is, however, often uncertain, and in many cases unknown. If debility furnish the leading clue to explain the phenomena of fever, we can scarcely explain its operation or connection with every symptom; nor can we say why, when its cause is removed, the effect should not cease. In the disease just mentioned, dropsy, we can scarcely in any instance see the particular cause of the increased exhalation or diminished absorption; nor, as we have found, can we rest on either any clear discriminated indications of cure. We must, therefore, often collect rules from experience, and connect them with the more obvious causes and the more certain changes in the constitution when deviating from the healthy state.

CAU'SIS, (from καίω, *uro*, to burn). See AMBUSTA.

CAUSO'DES FE'BRIS, (from καίω, to burn). See FEBRIS ARDENS.

CAUSO'MA, (from the same). In Hippocrates signifies a burning heat and inflammation.

CAU'STICA. CAUSTICS, (from καίω, to burn). See ESCHAROTICA.

CAU'STICUM AMERICA'NUM. See CEVADILLA.

CAU'STICUM COMMU'NE FO'RTIUS. Ph. Lond.

The common stronger caustic of the London college, called now CALX CUM KA'LI, is made by adding five pounds four ounces of quick lime, to water of pure kali, sixteen pounds. The water of pure kali is reduced by boiling to a fourth part; and the lime reduced to a powder by the affusion of water gradually added. It must be kept in a vessel close stopped. For the mode of application see ESCHAROTICA.

CAU'STICUM LUNA'RE. See ARGENTUM.

CAU'STICUM OPIA'TUM. OPIATED CAUSTIC.

R. Calcis cum kali puro 3 ij. opii pulverisati 3 ss. saponis mollis q. s. commisceantur calx cum kali puro, et opium, et in pastam cum sapone molli formentur. This is used in the radical cure of an hydrocele, by forming, of adhesive plaster spread on leather of several thick-

nesses, a circular aperture adapted to the lower and anterior part of the tumour, in which the paste is introduced. This is to continue for about eight hours, about which time it will, without much pains, penetrate down to the tunica vaginalis. Afterwards apply poultices till the eschar sloughs: then the water is evacuated, and the cure completed. This is Mr. Else's mode at St. Thomas's Hospital.

CAU'SUS, (from καίω, *uro*, to burn). See ARDENS FEBRIS and DIPHAS.

CAUTE'RIMUM, (from καίω, to burn). A CAUTERY, either actual or potential. See ESCHAROTICA.

Cauterium Potentielle Ph. Edinb. The POTENTIAL CAUTERY of the Edinburgh Dispensary.

Take of Russian potash and quick lime, of each equal parts; of spring water three times the quantity of the whole; macerate them for two days, occasionally stirring them; then filter the ley, and evaporate it to dryness; put the dry mass into a crucible, and urge it with a strong fire till it flows like oil; then pour it out upon a flat plate made hot, and while the matter continues soft cut it into pieces of a proper size and figure, and keep them in glasses closely stopped.

This is also called *lapis septicus*. It is a strong and sudden caustic, but it deliquesces too soon in the air, and runs beyond its proper bounds; indeed, the suddenness of its action depends on its disposition to liquefy. But this inconvenience is avoided in the calx cum kali puro. Ph. Lond. 1788.

CA'VA VE'NA. The principal vein, which receives the reflux blood, and conveys it to the heart, is thus named, from its size.

The *vena cava* is generally described as being two; viz. the ascending and the descending; the right auricle receives them both, one at its upper, the other at its lower part.

The superior *vena cava* receives the blood principally from the thorax, head, and upper extremities, with a very small proportion from the parts below the diaphragm.

The inferior *vena cava* receives the blood principally from the abdomen and lower extremities, and very little from the parts above the diaphragm.

The ancients called the *vena cava* superior, the *vena cava ascendens*; and the *vena cava* inferior, *vena cava descendens*.

According to Winslow, who is extremely accurate in his description of the blood vessels, the superior *vena cava* runs down to the right auricle of the heart, almost in a direct course, for about two fingers' breadth within the pericardium, on the right side of the aorta, but a little more anteriorly. Above the pericardium, it runs down from the cartilage of the first true rib, and a little higher than the curvature of the aorta; here it receives two branches, viz. the right and left subclavian veins. The trunk of this upper *vena cava*, above the pericardium, to the just named bifurcation, receives anteriorly the *vena mediastina*, *pericardica*, *diaphragmatica superior*, *thymica*, *mammaria interna*, and *trachealis*. All these are called *dextræ*. Their fellows on the other side are called *sinistræ*; they do not fall into the trunk of the *vena cava*, but into the left subclavian vein. Posteriorly, a little above the pericardium, the trunk of the *vena cava* receives a capital branch, called *vena azygos*. It runs down by the ver-

tebræ dorsi, almost to the diaphragm, composed of the greatest part of the venæ intercostales and lumbares superiores.

Hardly a quarter of an inch of one side of the *vena cava* inferior is contained in the pericardium; from thence it immediately perforates the diaphragm, receiving the venæ diaphragmaticæ inferiores, or phrenicæ: it passes behind the liver, through the great sinus of that viscus, from which it receives venæ hepaticæ. In this course it inclines towards the spina dorsi and aorta inferior, the trunk and ramifications of which it accompanies all the way to the os sacrum, the arteria cœliaca and the two mesentericæ excepted. Arrived at the os sacrum, the two iliæ unite to form its trunk, joined by the hypogastricæ, and some other branches distributed into the pelvis. Under the ligamentum Fallopii they take the name of crurales, each of which receives the blood from the lower extremities.

CA'VAN, dicta THO'RA PA'ROU. See CAJAN.

CAVE'RNA, (from *cavus*, hollow). A CAVERN. See also PUDENDUM MULIBRE.

CAVIA'RUM, (from *caviar*). It is the pickled roe of the sturgeon.

CAVI'CULA, and CAVI'LLA, (from *cavus*). See ASTRAGALUS, and also CUNEIFORME OS.

CA'VITAS INNOMINA'TA, (from the same). See AURICULA.

CA'YENNE, CA'YAN. See PIPER INDICUM.

CAYU'TANA LU'ZONIS. See FAGARA MAJOR.

CA'ZABI. See CASSADA.

CEANO'THOS, (from *κεεῖ αἰώθειν*, because it pricks at the extreme parts). See CARDUUS HÆMORRHODALIS.

CEANO'THUS. See CELASTUS INERMIS.

CEA'SMA, (from *κεῖω*, to split, or divide). A fissure or fragment.

CEBIPI'RA *Brasiliënsibus*. (Indian.) *Guacu*, or *Miri*. A tree which grows in Brasil. Its bark is bitter and astringent, and the decoction is employed in baths and fomentations for the relief of pains in the limbs, diseases from cold, tumours of the feet and belly, itch, and other cutaneous diseases. It is figured by Margrave in his plants of Brasil, p. 100, but its botanical place has not been ascertained.

CE'CIS, (from *κηκίω*, to spring). A GALL of the OAK. So called because it springs suddenly from the oak. See GALLÆ.

CECRY'PHALOS, (from *κρυπῶ*, to hide). The net in which women confined their hair (Hippocrates). It is also applied to one of the stomachs of ruminating animals. See ABOMASUM.

CE'DMA, (from *κεδαω*, to disperse). See PUDENDAGRA.

CE'DRA, ESSE'NTIA DE. See BERGAMOTTE.

CE'DRELÆ'UM, (from *κεδρος*, the cedar tree, and *ελαίον*, oleum). OIL of CEDAR. See CEDRIA.

CE'DRE'LTE. According to Bellonius, this word is derived from *ελατη*, the fir tree, and *κεδρος*, the cedar, because it grows like the fir. Among botanists it signifies that species of cedar which is said to exceed all other trees in size.

CE'DRIA, (from *κεδρος*, the cedar tree). It is called the PITCH and the RESIN of the great cedar tree, and it is the crude tears of the cedar. It has been supposed

different from the cedrium, or oil of cedar, which is more fluid; but, by writers in general, it is called *cedria*, *cedrium*, and *cedrelæum*. Gorræus and Pliny observe, that the great cedar yields a pitch called *cedria*, to which Galen gives the same appellation with many others. Salamasius says, that the Arabians call the oil of cedar *ketran*, or *alketran*; and we, by a corruption of that word, give the name of *cedrium* to the pitch which is used for ships. Though the Greeks confound *cedrelæum* with *cedria*, they are not the same; for the *cedria* is the pitch, or resin, that distils from the cedar tree; and the *cedrelæum* is an oil obtained from the pitch or resin, and which swims above it in boiling, and is collected with wool. Dioscorides remarks, that the best *cedria* is thick, pellucid, and of a nauseous smell; when poured out it does not spread, but collects in drops, and preserves dead bodies from putrefaction: it does not, however, appear to be really known what the *cedrium* is.

CE'DRI'NUM LI'GNUM. See JUNIPERINUM.

CE'DRI'NUM VI'NUM. CEDAR WINE. Take thin pieces of wood, just cut from the tree, while the fruit is on it, and expose them to the sun, or a fire, to obtain their juice by exudation. A pint of this juice is mixed with six pints of wine. After standing for two months they are decanted into another vessel, and exposed for some time to the sun. The wine is then fit for use.

In the same manner are prepared wines from juniper, pine, cypress, bay, and the wood of some other trees. All these wines are heating, diuretic, and astringent; the bay wine is particularly so.

Cedar wine is also prepared by mixing half a pound of the bruised berries with six pints of must. The whole placed in the sun for forty days, and is then proper for drinking.

CE'DRINUM is a name for the composition of wax and resin used for ships. See CEDRIA.

CE'DRIS. See CEDRUS.

CE'DRI'TES, is wine in which the resin that distils from cedar trees has been steeped.

CE'DRIUM. See CEDRIA, and PIX LIQUIDA.

CE'DRO and CEDROME'LA, (from *κεδρος* and *μυλον*, an *afyle*). See CITREUM.

CE'DRONE'LLA, (from *κεδρος*, because it is produced by a sort of cedar tree). See MELISSA.

CE'DRO'STIS, (from *κεδρος*; because it smells like the cedar). See BRYONIA ALBA.

CE'DRUS, (from *Kedron*, a valley where it grew in great abundance,) *cedrus conifera foliis laricis*, *cedrus Libani*, *cedrus magna*, *larix orientalis*. The *pinus cedrus* Lin. Sp. Pl. 1420. The GREAT CEDAR OF LIBANUS. Nat. order *conifera*. It is referred by Tournefort to the genus *meleza*, and by Jussieu to the *juniperus*.

Modern botanists cannot find cedar trees that agree with the scriptural description of their loftiness; but this tree, according to the similitude of the Psalmist, spreads its branches very extensively. Maundrel, in his travels, says he measured the trunks of some old cedar trees, and found one to be twelve yards in circumference, and thirty-seven yards in the spread of its boughs. Its native spot seems to be Mount Libanus, where it grows in a dry, stony soil; but even here its numbers were diminishing. Rawolf, in 1574, found

only-twenty six, with no young ones; Maundrel, 100 years afterwards, could discover but 16: there were, however, many young ones. Pocock also found a great number of young thriving cedars on the mountain.

The cedar of Lebanon is an evergreen coniferous tree, with very narrow, stiff, sharp pointed leaves, standing several together in tufts. Its fruit is called *cedris*. It is a native of the bleak snowy mountains of Syria, and is not as yet become common in England. As a medicine, it differs very little from the virtues of the fir tree. Its smell is considerably more agreeable, and the resinous juice extracted from the trunk of the cedar tree, by incisions, is more disposed to concrete into a solid brittle mass than that from the fir tree; nor does the matter which distils from the cedar tree lose much of its finer parts in drying: even boiling water does not easily carry off the flavour of cedar wood.

By distilling the wood with water, a small quantity of essential oil is obtained, which congeals in a moderate degree of cold. The decoction, in the still, affords an extract by evaporation, which smells considerably of the wood, and is in taste bitterish and saline. In the saline nature of this extract, this wood differs from all the resinous ones that have been examined. Margraff says, that the saline part which crystallized in the extract was common salt.

The wood of the cedar is very incorruptible, though it is not probable that cedar wood formed the roof of the temple of Apollo at Utica, supposed to have remained with little change for 2000 years. The fragrance of the wood drives away moths; and, internally, the productions of the cedar and the junipers differ little from the turpentine. See JUNIPERUS.

CE'DRUS CUPRESSI, *juniperus Lycia* Lin. Sp. Pl. 1471.

It is a shrub with yellow flowers, and fleshy leaves, placed four together, like those of cypress. The flowers are followed by a round fruit like a mulberry in taste and smell, and of a purple colour when ripe. In this fruit are three or four seeds, which smell like resin. Until this tree is three or four years old, its only distinction from the juniper bush is, that its leaves are softer and shorter. It grows in many of the southern parts of Europe. Its medicinal qualities are like those of juniper. Dale informs us of another species which he found in Carolina, and which affords a gum so like the true olibanum, that, when mixed, they cannot be separated. Hence he concludes, that this is the tree that affords the olibanum. It is probably the *juniperus thurifera* Lin. Sp. Pl. 1471.

CE'DRUS AMERICA'NUS. See THUYA.

CE'DRUS BACCI'FERA, SABINA. *Juniperus sabina* Lin. Sp. Pl. 1472. See SABINA.

CE'DRUS CE'ES. See CRINONES.

CE'DRUS PHENI'CIA, called also *thuya Massiliensium*, *juniperus* è Goa, *cedrus* è Goa, *sabina Goensis*, and *juniperus Caroliniana*. A variety probably of *pinus cedrus*. Its virtues are similar to those of juniper.

CELA'STRUS, (from *κελς*, a dart or pole, which it represents). *Ceanothus Americanus* Lin. Sp. Pl. 284.

Some noted Indians depend more on this than on the lobelia for the cure of syphilis, and use it in the same manner as the LOBELIA, which see. If the disorder

is exceedingly virulent, they mix some of the roots of the *rubus occidentalis* Lin. Pl. 706, with it.

CE'LE. *Κηλη*, a TUMOUR, (from *κελεω* to swell out,) the protusion of a soft part; a rupture.

CE'LERI ITALO'RUM. A corruption of *selinum*, (Ital.). See APIUM.

CELLULÆ MASTOIDEÆ, (a dim. of *cella*, a cell). These are very irregular cavities in the substance of the mastoid apophysis, which communicate with each other, and have a common opening towards the inside, and a little above the posterior edge of the orbicular groove. These cells are lined by a fine membrane, which is partly a continuation of the periosteum of the tympanum, and partly seems to be glandular, like a kind of *membrana pituitaria*. The mastoid opening is opposite to the small opening of the Eustachian tube, but a little higher. See AUDITUS.

CELLULO'SA MEMBRA'NA. The CELLULAR MEMBRANE. It is called *tela cellulosa*, *fanniculus adiposus*; *membrana adiposa*, *pinguedinosa*, et *reticularis*; in French, *tissue cellulaire*, *tissue muqueux*, and *l'organe cellulaire*. This membrane is of the greatest extent, and of the utmost consequence in the human structure; for it connects and penetrates into every part; indeed it seems to be the very constituent of most, if not all, the parts that are called the solids in our bodies. Experiments prove that all membranes, without exception, and the vessels, which are hollow membranes, the parenchymatous substance of the viscera, ligaments, and a great part of the bones, either are or have been cellular texture. The cellular membrane, when compacted in different degrees of density, forms these solids. Air introduced under the skin diffuses itself through all the surface of the body, penetrates into the interstices of the muscles; and Haller asserts, that even the vitreous humour of the eye hath received the flatus of an emphysema.

Some describe the cellular membrane not as one, but as a congeries of many membranous lamina joined irregularly to each other at different distances, so as to form numerous interstices of different capacities, and which communicate with each other. These interstices they call *cellulæ*, and the substance made up of them cellular substance.

It is generally and properly considered as of two kinds, viz. reticular and adipose; and the latter is described as a connection of fibres, forming, by their different directions, cells for the lodgment of oil or fat. In some parts its substance is merely a net work of slender fibres, which give it ductility and looseness; for instance, under the skin of the penis and scrotum. In other parts it is more or less loaded with oil, and is less porous or spongy in its substance, as under the skin of the buttocks, and in the soles of the feet. Dr. Hunter uses the term cellular as the generic name, and the names reticular and adipose for expressing the two species. He also observes, that the reticular part is evidently dispersed through the whole body, except, perhaps, in the substance of the bones, of the brain, and in the humours of the eye; that it is found in a much greater degree in the belly of muscles than in the tendons, in which it is scarcely discerned. He is also of opinion that the adipose membrane is composed of two kinds of cells; viz. the reticular, which communicate with each other; and adipose, which are di-

distinct, and are the reservoirs of the animal oil, or a white granulated matter, capable only of being fused by heat; the cells of which are called *sacculi adiposi*. He urges, as a proof of his opinion, that the water in an anasarca goes downward while we are in an erect posture, but the oil does not. The oil is supposed to be secreted by the small arteries, and occasionally absorbed into the circulation. Dr. Hunter thinks that wherever there is fat in the human body, there is a particular glandular apparatus superadded to the reticular membrane, consisting of vesicles, or bags, for lodging the animal oil, as well as vessels fitted for its secretion.

Whether or no the cellular membrane be the basis of all the organized and vascular parts of our frame, Dr. Hunter hath proved that the most simple parts of it are vascular; that the callus, which unites broken bones, is itself bone, and also vascular; that the morbid adhesions, between different adjacent parts, are vascular, and that a cicatrix in the skin is vascular. He infers from hence, that all our solids are organized; and that, whether lengthened or renewed, they shoot in a vascular form. But here he speaks of the visible parts. We suspect, however, that the importance of this connecting reticular texture has been greatly exaggerated. We see in it nothing but connecting threads, which any condensed glutinous substance forms; and, if the cells communicate through the whole body, it is no more than may be expected from the union of different separate organs. If these are united in one part, they are separated in another; and we can easily see that by some passage all may communicate.

It has been said, that membranes are formed of this substance. We know that, when condensed, it will assume a membranous appearance; but we have no evidence of it in any case possessing nerves or organization, like what we may style *primordial membranes*. The effused gluten, between the pleura and lungs, assumes this form; but we cannot say that this is an organized substance. The cellular texture never appears to be vascular: even in a state of inflammation it is never sensible. It is the seat of an abscess, but is not itself inflamed. Nerves pass through it, but are never lost on it. The former editors of this work have suggested, that it may be formed from the coats of the nerves; but these are never deposited except at their minutest extremities, where the nervous power acts with its peculiar functions. This never occurs in the cellular substance, except of the muscles; and it would be a gratuitous assertion, that such was the origin of the cellular substance in muscular flesh, when, in every other part of the body, no such source could be traced. In fact, we see in every part of the cellular substance only hardened gluten, without either a nervous or glandular apparatus. Whether the adipose membrane differs in its structure we doubt. There is some reason to think so: but we must remember that, if one part of the cellular substance be filled, the surrounding membrane is thickened; and this will account for the retention of the fat in those cells where it is deposited. Among the uses of this membrane, the following are sufficiently obvious.

1. It fills up interstices, and gives an agreeable contour to the body.

VOL. I.

2. It is a cushion to defend against pressure, hence it is of a thicker composition in infants.

3. It connects the parts of the body, but so as to admit of a sliding motion between them.

4. In some parts of the body it serves as a bed for more tender organs; as in the orbit and scrotum, as well as a reservoir for animal oil.

This membrane is the seat of abscesses, the leucophlegmatia, emphysema, anasarca. In a consumption it is shrunk up so as to be hardly visible; in an anasarca its oily contents are all destroyed; and in an emphysema almost its minutest parts are rendered visible.

On this article, see what Dr. Hunter says in the Lond. Med. Obs. and Inq. vol. ii. p. 26, &c. Haller's Physiology; Malpighius on the Cellular Membrane; Dr. Shebbear in his Theory and Practice of Physic; also Recherches sur le Tissu Muqueux, ou l'Organe Cellulaire, par Mons. Theoph. de Bordeu.

CELLULO'SA TU'NICA RU'YSCHII. See INTESTINA.

CELOTO'MIA, (from *κηλη*, *hernia*, and *τεμνω*, *to cut*). See CASTRATIO and HERNIA.

CELSA. It means the beating of the life, or of the life's blood; and is a barbarous term of Paracelsus.

CELTIS. A celsitate, from its height. See LOTUS ARBOR.

CEMENTA'TIO. See CEMENTUM and CORROSION.

CEMENTE'RIMUM. See ALUDEL.

CEN'CHRAMIS, (from *κεγχρος*, *millet*). See FICUS SATIVA.

CEN'CHRIUS, a species of HERPES, called, from its resembling *κεγχρος*, *millet*. See HERPES, Bell's Spec. 3d.

CENCHROS. MILLET, (from *κεγχρος*, *dry*; because it is a very dry seed). See MILLIUM. These seeds are also called *cenchreides*; and, in Hippocrates, we find the words *κεγχραιδες ιδρωτες*, *miliary sweats*.

CENEANGIA, (from *κενος*, *vacuus*, *inanis*, and *αγγος*, *vas*), is an emptiness of vessels from abstinence. It is sometimes thought to mean, primarily, a spontaneous evacuation of blood from the vessels; and, consequently, that which is artificial may be meant by this term. In some dissections the vessels have been found remarkably empty; but this appearance has not been connected with any concurrence of symptoms.

CENEO'NES, the FLANKS, from *κενος*, *empty*.

CENI'GDAM and CENI'PLAM, and CENI'GOTAM and CENI'POLAM. The name of an instrument anciently used for opening the head in epilepsies.

CENIOTE'MIUM. A purging remedy, formerly used in the venereal disease, supposed to be mercurial.

CENO'SIS, (from *κενος*, *empty*). EVACUATION. CENOSIS imports a general evacuation; catharsis the evacuation of a particular humour which offends with respect to quality, and almost exclusively from the alimentary canal.

CENTAUREA BENEDI'CTA. See CARDUS BENEDICTUS.

CENTA'UREA CENTAU'REUM. See RHAPONTICUM VULGARE.

CENTAURIODES. See GRATIOLA.

3 D

**CENTAURIUM**, (from *κένταυρος*, a centaur). This herb is called **CENTAURY**, because it was feigned that Chiron, the centaur, cured with it Hercules' foot, which had been wounded with a poisoned arrow. It is also called **CHIRONIA**.

**CENTAURIUM MA'GNUM**, **MA'JUS**. See **RHAPONTICUM VULGARE**.

**CENTAURIUM MI'NUS**, or *lesser centaury*. It is the *gentiana centaurium* Lin. Sp. Pl. 332. Nat. order *rotaceæ*. It is annual, grows wild in dry pastures, and among corn. It flowers in July; and is sometimes called the *febrifugia*.

The leaves and tops are pure bitters, having scarcely any smell or flavour, and agree with the gentian root.

The seeds are bitter, but the petals of the flowers and roots are almost insipid. The flowery tops are the parts chiefly useful.

Its active parts are readily dissolved by water, or rectified spirit of wine. Water takes up with the bitter an insipid mucilage; but spirit, the bitter part only. The watery extract is consequently more in quantity, and less bitter; and the spirituous less, but more bitter. Cartheuser says, that one ounce of the herb yields about half an ounce of the watery extract, and scarcely two scruples of the spirituous. The centaury is justly esteemed to be the most efficacious bitter of our indigenous medicinal plants; and has been recommended as equal or superior to gentian. Dr. Cullen observes that, though the extract of this plant is said to be less agreeable than that of gentian, he can find no difference, and thinks that, as cheaper, it is preferable. It is considered as strengthening and stomachic; and, as out of the body centaury manifests an equal degree of antiseptic power with gentian, similar medical effects are ascribed to it. It is given in atony, dyspepsia, and jaundice. The flowery tops are infused as tea, and a tea cupful administered three or four times a day: but they may be taken in powders, or the decoction inspissated into an extract like wormwood. See Neumann's Chem. Works. Lewis's and Cullen's Mat. Med.

**CENTIMOR'BIA**, (from *centum*, a hundred, and *morbus*, a disease; so called because it was supposed capable of curing a great number of diseases). See **NUMMULARIA**.

**CENTINE'RVIA**, (from *centum*, and *nervus*, a string; so called from the many ribs upon its leaves). See **PLANTAGO**.

**CENTINO'DIA**, or **CENTINODIUM**, (from *centum*, and *nodus*, a knot; so called from its many knots or joints). See **POLYGONUM**.

**CENTI'PEDES**, (from *centum*, and *pēs*, a foot). See **ASELLI**.

**CENTRA'TIO**, (from *centrum*, a centre). The degenerating of a saline principle, and contracting a corrosive and ulcerating quality. Hence *centrum salis* is said to be the principle and cause of ulcers. **Paracelsus**.

**CE'NTRE PHRENI'QUE**. See **DIAPHRAGMA**.

**CE'NTRION**, (from *κέντρον*, a spur). An epithet for a plaster mentioned by Galen, calculated against stitches in the side.

**CE'NTRUM**, in chemistry, is the principal residence, foundation, or source of any thing; in medicine, that

part in which its virtue resides; in anatomy the middle point of some parts.

**CE'NTRUM NERVE'UM**. The tendinous part of the diaphragm, which hath a triangular appearance: it is called also *centrum tendinosum*.

**CE'NTRUM OVA'LE**. Vieussens first gave this appellation to a part of the *corpus callosum*. It is convex, and of the form of the cerebrum. See **CEREBRUM**.

**CENTU'NCULUS**, (from *cento*, a quilt or mattress, which was formerly made of this herb). See **ALSINE**, and **GNAPHALIUM**.

**CE'PA**, (from *κερός*, a wool card; from the likeness of its root; or *capitis magnitudine*, from the size of its head). The **ONION**. *Allium cepa* Lin. *cromyon*, et *agrumina*. Nat. order *liliaceæ*.

The common onion is a plant too well known to need any description of its botanical character. It is chiefly cultivated for culinary uses: its root affords a large proportion of alimentary matter, particularly when boiled, as it shows by some sweetness and a large proportion of mucilage, when its acrimony is exhaled. In its fresh state it is acrid and stimulating. In bilious dispositions it produces flatulence, thirst, and headach; but in cold and phlegmatic temperaments is warming, attenuant, and promotes both expectoration and urine. It is powerfully antiseptic, and, if applied to tumours, promotes suppuration.

The root is the most active part; but it loses much of its virtue by drying. Distilled with water, all its flavour and acrimony arise. The active matter is much more volatile than that of garlic, but in other respects they agree, though the onion is much weaker, less acrid, and more mucilaginous.

Onions have a greater effect than any other alkaline plant in dissolving gravelly concretions. The expressed juice has been serviceable in deafness (see **ALLIUM**). Neumann remarks, that the characteristic principle of this root is its essential oil, though it cannot be collected in a separate state. See Lewis's Mat. Med. or Neumann's Chem. Works. Cullen's Mat. Med.

**CEP'E'A**. A small species of onion, which used to be esteemed for sallads in spring, but is not now regarded. See **BECARUNGA**.

**CEPHALÆ'A**, (from *κεφαλή*, head). A long continued pain in the head. See **CEPHALALGIA**.

**CEPHALALGIA**, **CEPHALA'GIA**, (from *κεφαλή*, the head, and *αλγος*, pain). The **HEADACH**. It is also named *cephalæ*, *cephaloponia*, and *homonophagia*. It is sometimes used to signify a dull pain of the head, of a short duration; but most frequently it is the appellation of pain in the head in general, without regard to circumstances, and is sometimes acute, and sometimes chronic. When mild it is called *cephalalgia*; when inveterate, *cephalæa*. When one side of the head only is affected, it takes the name of *hemisrania*, *migrana*, *hemipagia*, and *megrim*: in one of the temples only it is entitled *crotaphos*; and that which is fixed to a point, generally in the crown of the head, is distinguished by the name of *clavas hystericus*: q. v.

The nervous membranes of the head are the general seats of its pains, as the pericranium, the skin, dura mater, the membrane which covers the sinus in the os

frontis, &c. This complaint is considered as symptomatic by Dr. Cullen; but as an idiopathic affection by other nosological writers. See Vogel, Sagar, Linnaeus, Macbride. Sauvages places it under his seventh class *dolores*, and second order *dolores capitis*; of which the *cephalgia* and *cephalæa* form two distinct genera. See *Nosologia Methodica*, vol. ii. p. 49.

Undoubtedly pain of the head is often symptomatic; yet, as in many cases it is impossible to ascertain the disease of which it is a symptom, and in some is unconnected with any other complaint, it must be often considered as idiopathic. When we explain the arrangement of diseases, we shall find it difficult to avoid an order, at least, of *dolores*; and under this head *cephalgia* must be arranged. If we were already to anticipate definitions, which we have cautiously avoided, we would say that it is a pain confined to the forehead and occiput, unconnected in every instance with the bones of the face, except when periodical. In this way it is at once distinguished from the *tic dolooureux* (the *dolor crucians faciei* of Fothergill), diseases of the teeth, of the different antra, and of the eyes.

In this view, headach is a disease of the brain when idiopathic; and, though a symptom of apoplexy, of mania, and other diseases, yet, when alone and uncombined, when the series of symptoms which distinguishes these diseases is absent, and headach alone present, it must certainly be considered as of itself a disorder. As such, we find it produced by extraneous bodies pressing on the brain. These have been bony fragments, separated from the internal table of the skull, irritating the brain, while the accident that occasioned their separation was, at a distant period, unknown or unobserved. In some cases no such accident seems to have occurred; and the cause, only discovered by dissection, is unknown. The irritating bone has, in some instances, not been separated; but, has sprouted from the internal table of the skull in the form of an exostosis. This seems to be the cause of the obstinate headachs arising from an old neglected venereal complaint; headachs which we have sometimes seen terminating in epilepsy. The falx has been found to be bony, without producing headach; and, on the contrary, the meninges of the brain have been discovered in a thickened state after headachs the most violent. In the last case it is probable that the thickening of the membranes was owing to chronic inflammation; and that the latter occasioned the pain. The pineal gland has been sometimes found hard, and filled with stony concretions, which seem to have been the cause of obstinate headachs; and Dr. Blanc has found a tumour in the situation of this gland occasion the disease, as well as aneurisms of those branches of the carotids that surround the *sella turcica*. The distinction of these cases is very difficult: the pain is not always constant. In some instances it is violent only when the circulation is greatly accelerated; in others it occurs irregularly, without any obvious cause for its exacerbations. We have not mentioned the worms generated in the brain, recorded by Schenkus, as this author's narratives are more often wonderful than probable; and abscess in the brain more often produces lethargy and coma, than cephalalgia.

It may be doubted whether other causes do not sometimes produce pain in the head, which are still less

easily traced. Accumulation of water often occasions uneasiness and symptoms of irritation, before those of compression come on. The peculiar kind of circulation through the brain; viz. the collection of the venous blood in sinuses, greatly favours accumulation, and may be a cause of pain. We hear also of a spasmodic contraction of the meninges; and the idea has been supported by a peculiar feel, as if the brain was grasped by a strong hand. Yet we cannot admit of the contraction of a membrane in which no muscular fibres are discoverable, and the sudden distention of their vessels may produce the peculiar sensation just mentioned. We find also cases of mania and idiotism, where violent pain preceded the irregular exertion or extinction of the mental powers, in which the brain has been found unusually dry, or peculiarly soft. We know not the cause of these changes; nor can we trace the connection of their effects; yet, as they have been causes of pain, we may suppose that, in some obstinate cases, they may produce this symptom without proceeding to similar distressing terminations. There is at times a morbid sensibility, the concomitant often of genius, which predisposes to, or causes, this disease. It seems as if the man of genius suffers from the same source that gives him the superiority to the rest of mankind. In such a constitution, as in inflammations of the skin, of the eye, or ear, a fly may excite pain; a ray of light, or the slightest sound, be more pungent than the mid-day sun, or the explosion of a mine.

We shall mention hæmicrania as an idiopathic pain of the head, though by some authors it is referred to intermittents; by others to rheumatism. We mean to treat of it, however, more particularly under its own appellation.

On a review of these causes of idiopathic headach, we must regret that the source of so few cases is discoverable, and that we have scarcely appropriate remedies for any of those which we can ascertain. In general, in every instance, the necessity for keeping the bowels free, must be obvious from what we have said under the article of CATHARTICS. A drain also from the head, by a perpetual blister on the vertex, to the bone of the neck, or behind the ears, must be equally so. Avoiding accumulations and flatulencies in the stomach, for the reasons formerly assigned (see CATHARTICS), must be advantageous. Emetics are often advised for this purpose; but they are doubtful remedies, as they determine so powerfully during their action to the head. Yet we suspect that they are not injurious, since their inconvenience is transitory, and their beneficial effects durable; and we shall find them peculiarly useful in symptomatic headachs. As a remedy for flatulence, the fetid gums will probably be useful, even in idiopathic cephalalgia; and, if joined with aloes, will be more serviceable. From the effects of camphor in fevers, we suspect that it may be useful in headach; and with nitre we have often employed it with advantage. It is a too common practice to cut off the hair, partly because it is supposed to keep the head warm, and partly that cold applications may be more conveniently employed. This practice has not, however, the sanction of long experience; nor is it supported by reason. Each hair is a vegetable, nourished by a bulbous root, supplied by numerous blood vessels. These, though small, from their number

convey no inconsiderable quantity of fluids; and as the external and internal carotids arise from a common trunk and anastomose in some of their branches, whatever cause increases the circulation in the former must lessen it in the latter. The author of this article suffered for many years an irregularly returning paroxysm of headach, for which he could assign no cause; but at last discovered that it frequently returned after shaving the head. He suffered his hair to grow, and from that time it gradually lessened in violence, in duration, and the frequency of its return. From being a complaint highly serious, and beginning to affect the memory, its returns are now rare, and never so violent as to unfit him for any exertion of body or mind.

Among the means of lessening the force of the circulation in the head, we should, perhaps, have mentioned more early, the use of slight occasional bleedings; the application of leeches or cupping glasses. They are all occasionally useful. In such cases, too, the temporal artery has been sometimes opened with the best effect.

The diet in those subject to headach should be light, cooling, and moderate in quantity: the usual drink, water, with a moderate quantity of the wine most suitable to the constitution. The white wine is generally preferable. The mind should be kept calm; all the more violent exciting passions avoided; the exercise moderate, and never in the heat of a summer day, or under a warm sun. The apartment should be large; the sleeping room lofty and well ventilated; the head raised high on the pillow. In short, every thing that accelerates the circulation, or determines the blood to the head, should be carefully avoided.

Symptomatic headach is a disease of so many organs, that it is impossible to "fix the variable Proteus by any chain." Headach attends fevers of almost every kind; and, when the infinite variety of forms of fevers are considered, so many must there be of cephalalgia, as a symptom of this complaint only. Every obstruction in the bowels, every accumulation of sordes, or indigestible matter in the stomach, produces the same disease: every obstruction to the regular evacuation of any gland, particularly those of the surface, has a similar consequence; every nervous affection, either from excessive excitability or exhaustion. Are we then to be surprised at its frequent occurrence? Is it not wonderful that the head is ever free from pain? But to be more particular.

The sympathy between the head and stomach has been so generally observed, it is the subject of such constant experience, that to enlarge on it would be superfluous. We have already observed how difficult it is to ascertain the organ primarily affected. The apprehension of increasing any effusion in the brain, has made the distinction an object of peculiar anxiety; but we are confident in saying, that, in the doubtful cases, no hazard attends the exhibition of an emetic: we must repeat, the inconvenience is temporary, the advantages durable. We urge this with more force, as, with the experience of near forty years, we find the decision difficult and precarious: the tyro, without a suspicion of the difficulty, by the exhibition of an emetic has succeeded. If to this we add that headach is one of the first symptoms of fever, this plan has additional commendation. It must be followed by a cathartic; and, unless great weakness forbid, this cathartic must

be an active one: the foundation of its use has been already explained. In this way headach, whether idiopathic or symptomatic, will be usually relieved. If relieved only, and congestion in the head is obvious from heavy or inflamed eyes, languor and listlessness, a blister is no equivocal remedy, whatever may be the cause.

Headach, if a symptom of slow or obstructed bowels, is to be relieved in the same way by an emetic and laxative, but chiefly by the latter; and, in these circumstances, a moderate discharge, steadily continued, is more useful than temporary active purging. Eccoprotics are chiefly useful; and they should be long persisted in. The choice of the medicine must be determined by the causes. If the fault be in the biliary secretion, the purging mineral waters, soap, sometimes assisted by rhubarb, or neutral salts with the occasional use of calomel, will be useful. If a torpor of the intestines occasion the disease, the rhubarb, the aloes, and even the colocynth, will be necessary, as less active medicines will have little effect; if mucus involving worms, calomel, rhubarb, resin of jalap, and even gutta gamba. We doubt, however, whether worms be so frequent a cause of headach as has been supposed. The hydrocephalus was not long since styled a worm fever; and the early symptoms of irritation, accompanied by pain in the head, were attributed to these animals. Yet, as all accumulations in the bowels may occasion headach, those from worms must not be hastily rejected.

An obstruction connected with the bowels has been a very general cause of this complaint, we mean the suppression of the hæmorrhoidal discharge. In the whole circle of practical medicine, we know no question so intricate and difficultly explained as the connection of the hæmorrhoidal discharge with the general health; or rather, perhaps, the supposed connection, as stated by the German physicians. We have not found, from our own observation, this connection; but the experience of ages must not be overlooked, or contemptuously disregarded. The hæmorrhoids were considered, at a certain period of life, as essential to the male, as the catamenia to the female, health: their appearance was hailed as a salutary omen, their disappearance dreaded as a dangerous symptom. To this subject we must return: we can only now say, that we have not found this discharge necessary, except when established as an habitual one. We have found its repulsion injurious, and indeed so is that of every habitual discharge. Yet there is evidently some connection between the state of the rectum and the general health; for the fistula, or an abscess in ano, often relieves hectic symptoms; and, to check or stop the discharge, is often injurious, and generally fatal. It was supposed, that as the veins of the abdomen centered in the vena portæ, the depletion of these would lessen an obstructed circulation in the liver. But the hæmorrhoidal veins do not form a part of the vena portæ, and this system is of course untenable. The inconvenience that arises, must consequently be attributed to the suppression of an evacuation, and particularly to that of a discharge, which increases the circulation in the descending aorta. The consequence, as we have already shown, must be a greater determination to the ascending.

Another defect constantly attended with headach is that of the catamenia, whether they have not appeared

or been suppressed. The chlorosis we shall soon notice, but it must be under the disadvantage of not having considered the cause of menstruation. We should have explained this subject under catamenia but were unwilling to disturb the former arrangement too rashly, as it involved such numerous references. If plethora or spasm obstruct the menses, the disease of the head is obviously accounted for: if weakness or inanition render this discharge insufficient, the effect is not so easily explained. The complaint is, however, attended with general debility; every discharge is equally suppressed, and an irregular balance of the circulation is the consequence. With the greatest weakness, with a complexion which shows that the red globules, that index of tone and general health, are deficient, the head is loaded, and hæmorrhages from the nose are not uncommon. A similar complaint with headach often occurs in boys about the age of puberty. In these diseases, active cathartics, particularly those whose activity is exerted on the rectum, are the chief remedies, though in chlorosis, tonics must be also employed.

Repelled fluids from the surface produce very constantly symptomatic cephalalgia. The simplest case of this kind is coldness of the feet; but damp cold weather, with an easterly wind, will in many constitutions bring it on. Partial colds produce rather fever or rheumatism; but in both the head is usually affected. A more severe cause of this kind is the repulsion of acrid matter from the surface, by the application of astringent washes to herpes, or tetter; by saturnine or mercurial applications as cosmetics: from these the head generally suffers, though the mischief is often more extensive, and apoplexy, cachexy, slow fever or epilepsies, are frequent consequences. Repelled gout is a still more serious cause. See ARTHRITIS.

There are causes of headach that act more mechanically. Whatever, for instance, retards the current of the blood in the sinuses of the brain, or the veins which convey the blood from the head, will produce it. Of this kind are various tumours, particularly of the conglobate glands, polypi, exostosis, &c. Whatever prevents the free evacuation of the right auricle and ventricle, contributes to retard the motion of the blood in the veins, which discharge their contents on this side of the heart. More externally, rheumatic pains in the muscles of the head sometimes resemble so strikingly cephalalgia as to be mistaken for it.

We have not mentioned the mental causes, anxiety, fear, suspense, and grief; for these seldom produce the complaint until the body or, in general, the stomach is affected. The cephalalgia of students is often a nervous affection merely. Whatever be the action of the nervous fibres in intellectual operations, its excess is often a cause of pain; though, in many instances, the cephalalgia of students is connected with obstructions of the bowels, and very often with increased determination to the head. The hysteric cephalalgia partakes of this nervous cause, particularly when the pain feels as if a nail was fixed in the brain, from hence called the clavus hystericus. But to this subject we must return when we treat of hysteria.

Authors have endeavoured to distinguish by the particular kinds of pain which of these causes may have produced it, but language fails in describing the differ-

ent feelings, and their variety. An external soreness, points out an external cause; and, when the remote causes are attended to, we may, with little difficulty, ascertain the real nature of the complaint, and the practice will, of course, be obvious. Where the causes are beyond our reach, the disease may be mitigated, by attending to the directions given for relieving idiopathic headach.

Though the cure of these species of headachs depends on their causes, and we have given, in general, the outline, which will be filled up in treating of the diseases themselves, we may here add a few of the remedies which give immediate relief. One of these is bathing the feet in tepid water, rubbing them with flour of mustard, and keeping up a general circulation to the surface by flannel next to the skin. The effects of a blister we have already mentioned; but the aqua ammoniæ, or ether, applied to the nostrils or the forehead by the palm of the hand, often produce instantaneous relief, which authors have explained in the following manner:

A branch from the fifth pair of nerves is spread on the membrane that lines the nostrils, and another branch from the same passes through the foramen supercilii, and spreads on the teguments of the forehead; hence, when pain is in the eyeball and forehead, a heat is perceived in the nostrils; and benefit may be expected from external means, if applied to the membrana narium and to the forehead: alternate pressure near the superciliary holes of the frontal bones will also relieve.

CEPHALALGIA CATARRHALIS. See CATARRHUS.

CEPHALALGIA INFLAMMATORIA. See PHRENTIS.

CEPHALALGIA HERBA. See VERBENA.

CEPHALALGIA SPASMODICA. The sick headach. Though this afflictive malady scarcely differs from the symptomatic headach, arising from the stomach, yet, from respect to Dr. Fothergill, who first called our attention to it, we shall speak more particularly on the subject. He observes, that it is not the complaint of any particular age, sex, constitution, or season, but it is incident to all. The sedentary, inactive, relaxed, and incautious respecting diet, are the most exposed to it.

The patients, he observes, generally awake early in the morning with a headach, which seldom affects the whole head, but one particular part of it, most commonly the forehead; over one frequently, sometimes over both eyes. It is occasionally fixed about the upper part of the parietal bone, of one side only; sometimes the occiput is the part affected; or it darts from one place to another. From the time it commences until it wholly ceases, it is in different degrees. With this is joined more or less of sickness, which in some is scarcely sufficient, without assistance, to provoke vomiting, though in others this operation is easily excited. If this pain happens, as is most common, early in the morning, before any meal is taken, then phlegm only is thrown up, unless the straining be severe, when some bile follows. In this case the disease soon begins to abate, leaving a soreness about the head, a squeamishness at the stomach, and a general uneasiness, which induces the patient to wish for repose. Perhaps, after a short sleep, he recovers perfectly, debilitated only by

his sufferings. The duration of this conflict differs in different persons; in some it goes off in two or three hours; in others it continues twenty-four hours or longer, and with a violence scarcely to be endured, when the least light or noise produces most excruciating pain. In young persons it most commonly goes off soon; if it continues to harass them many years, as it sometimes happens, the fit is of longer duration, and leaves the whole system in so weak a condition as is not soon recovered. Its returns are very irregular; some suffer from it every two or three days, some in two or three weeks, others in as many months, or yet more seldom. Those who use but a little exercise, and are inattentive to their diet, are the greatest sufferers; costive habits are the most exposed to it; and habitual laxity of the bowels coming on has removed this complaint.

The disease is spasmodic; it attacks after digestion is performed, when the bile is supposed to have acquired its full activity, undiluted by fresh supplies of liquid: from numerous circumstances it appears to proceed from the stomach. For the most part it proceeds from inattention to diet, either in respect to kind or quantity, or both; and without exact conformity to rule in this respect, medicine proves ineffectual. Butter, pepper, or other spices, meat pies, rich baked puddings, drinking strong liquors, with a very free use of malt liquors, are supposed to produce it. Quantity as well as quality of diet is to be considered. Bile, if very acrid or bitter, is a frequent cause, unless in habits where the bile will purge, and these are rarely affected by this disease.

An emetic, or mild cathartic, and some time after it an anodyne, will carry off the complaint; but, as we have said, the fits will return after irregular and uncertain intervals. If disposed to costiveness, the belly should be kept open, by a regularly repeated laxative; and rhubarb, or aloes, is preferable to the saline purgatives. If acid abounds in the stomach, small doses of stomach bitters, with a little alkaline salt, or a chalybeate, once or twice a day, may be given; but in general, soap and pil. aloes cum myrrhâ, or magnesia and rhubarb, in small doses, daily continued, will often prove effectual. The following eccoprotic is highly useful: R. aloes succotorin. ʒi. rad. rhab. et rad. glycyrrhiz. incis. āā ʒ ss. infunde in aq. calcis ʒ viij. colaturæ adde tinct. lavend. ʒ ss. m. cap. cochl. i. ij. vel. iij. pro ne nata.

This disease is not the effect of any sudden and accidental cause, but of reiterated errors in diet, or in conduct, which, by weakening the organs of digestion, and otherwise disordering the animal functions, occasion frequent accumulations of indigested matter, and require a steady perseverance in the use of medicines. This change cannot be effected speedily; a patient observance of proper regimen, in respect both to medicine and diet, is necessary. The former ought, therefore, to be so contrived as to be taken without disgust for several weeks together, and to be repeated at proper distances, till the digestion is rightly performed, and the bile properly secreted and discharged. Unless the whole plan of diet, both in kind and quantity, accord with medical prescription, the benefits will be proportionally diminished. It demands attention to observe the just medium, and no less resolution

to keep steadily to the directions enjoined, particularly in respect to quantity. This must vary in different constitutions; but the first sensation of satiety is the surest proof of the meal having attained its proper limits. These patients are often subject to false appetite, a craving that does not arise from the demands of health, but from the morbid irritability of the stomach, which prompts them to eat more, and more frequently than nature requires, by which their sufferings are increased, and the disease gains ground.

See Dr. Fothergill's Works, 4to. edit. p. 597, &c. Medical Observations and Inquiries, vol. vi. p. 103, &c.

CEPHALA'RTICA, (from κεφαλή, *caput*, and ἀρτίζω, *to make clear*.) Medicines that purge the head. CEPHA'LEA JUVENUM. The HEADACH that often attends youth at the approach of puberty.

CEPHA'LICA, CEPHALICS, (from κεφαλή, *the head*, also *capitalia*,) remedies against disorders of the head. Dr. Cullen says, "however frequently employed, such a general meaning is sufficient to show the absolute impropriety of the term. It has been proposed to limit it to such medicines as have the power of increasing the energy of the brain and the activity of the nervous system. But in this manner it has been applied without any proper distinction and precision; and till this can be done, the term would be better laid aside." In general, authors mean by cephalics, cordials, and whatever promotes a free circulation of the blood through the brain.

In general, cool applications are useful cephalics, when inflammation prevails; but the ether, and the spirit of ammonia, as we have just observed, are more frequently useful. The old pharmaceutical works are full of formulæ under this title, to be applied as *capitones*, *frontals*, or in other forms, which modern practice wholly disregards. The medicines were generally of the stimulant kind. The herbals are equally full of medicines, which clear, which purge, which fortify the brain, under the name of cephalics. Perhaps errhines and sialogogues may have some effect in promoting a discharge; but these act on more general principles. The chief cephalics retained in some of the lists of the older authors are, the betony, the valerian, the lavender, the abrotanum, and the vanilloes.

CEPHA'LICA POLICIS. A branch from the cephalica vena, sent off from about the lower extremity of the radius, running superficially between the thumb and the metacarpus.

CEPHA'LICA TINCTU'RA, of a former edition of the Edinburgh Dispensatory, consisted of four ounces of wild valerian root, finely powdered; one ounce of Virginian snake root, powdered; half an ounce of the tops of rosemary; and six pints of white French wine; digested for three days, and then strained off. If to this were added two ounces of senna, one ounce of black hellebore, and two pints of French white wine, the cephalica tinctura purgans is formed. It is now totally disregarded, though it may be useful as a nervous or antispasmodic medicine; particularly in those nervous complaints connected with fullness of the vessels of the head.

CEPHA'LICA VE'NA. The CEPHALIC VEIN, called also *capitis vena*: because the head was supposed to be relieved by taking blood from it. It does not attend

any particular artery; it comes over the shoulder between the pectoral and deltoid muscles, and runs down the back part of the arm; when it arrives at, or a little below, the bending of the fore arm, it divides into two, below the outer, as the basilic does below the inner, condyle of the os humeri. The inner of the two branches of the cephalic vein is called *mediana cephalica*, and is the safest to bleed in. It is a branch from the axillary vein.

CEPHA'LICUS. Pu'LVIS. See ASARUM.

CEPHALINE, (from κεφαλη, the head). See LINGUA.

CE'PHALITIS, (from the same). See PHRENITIS.

CEPHALO'DES, (from κεφαλη, and ειδος, likeness). Shaped like a head, or having a head. It is applied to plants which are called CAPITATÆ, q. v.

CEPHALONO'SOS, (from κεφαλη, a head, and νοσος, a disease). This term is applied to a fever particularly affecting the head, and is frequent in Hungary. See AMPHEMERINA HUNGARICA.

CEPHALO PHARYNGÆUS, (from κεφαλη, the head, and φαρυγξ, the throat,) a muscle of the pharynx; called also *glossopharyngæus*, *mylopharyngæus*. It rises above, from the cuneiform process of the os occipitis, before the foramen magnum, near the holes where the ninth pair of nerves pass out; lower down, from the pterygoid process of the sphenoid bone, from the upper and under jaw, near the roots of the last dentis molaris, and between the jaws; it is continued with the buccinator muscle, and with some fibres from the root of the tongue, and from the palate. It is inserted into a white line, in the middle of the pharynx, where it joins with its fellow, and is covered by the constrictor medius, i. e. hyopharyngæus of Douglas. Its use is to compress the upper part of the pharynx, and to draw it forwards and upwards. See PHARYNX, and PTERYGO-PHARYNGÆI.

CEPHALOPON'IA, (from κεφαλη, head, and πονος, pain). See CEPHA'LALGIA.

CE'PHALOS, (from κεφαλη, the head; so called from the size of the head). See MUGILIS.

CEPHALO'TOS, (from the same). See CAPITATÆ PLANTÆ.

CERA, (from the Arabic *kira*, or the Chaldean *kera*). WAX. It is a concrete collected from vegetables by bees, and extracted from their combs after the honey is separated from them. It is wholly a vegetable production: and a similar substance is obtained from leaves. A little of the pollen only is added by the bee, which gives the colour, and increases the solubility; for yellow wax melts at 142°; bleached wax at 155°. Wax is evidently an oil coagulated by oxygen, which it certainly contains, though, according to Lavoisier's analysis, 100 parts of wax consist of 82.28 of carbon, and 17.72 of hydrogen. In distillation, a little water and some sebacid acid come over, next a very fluid odorous oil, which increases in consistence till it assumes that of butter, and is called *butter of wax*; but, by repeated distillations, Lemery reduced this to a very volatile oil. Acids have no effect on it: even the oxy-muriatic acid only whitens it. It is lighter than water, but heavier than proof spirit; and with the assistance of heat it is soluble in rectified spirit of wine; more so, according to Dr. Alston, than in oil. It is not at all soluble in aqueous liquors. With a

small degree of heat it is dissolved into the appearance of a transparent oil; and in this state it is easily miscible with oils, and any kind of fat. It readily takes fire, and burns all away; and all the wax, like camphor, is volatile in a certain heat. Inflammable vegetable oils may exist under the various forms of oil, butter, balsam, wax, resin, and pitch, according, probably, to the proportion of oxygen which they contain.

CE'RA FLAVA, YELLOW WAX, in the state it is taken from the combs, is, while fresh, of a lively yellow colour, tough, yet easy to break; hath an agreeable flavour, somewhat resembling honey: by long keeping it loses its colour, its agreeable smell, and becomes harder and more brittle. It contains, as we have said, a proportion of the pollen, furnished by the bee.

Distilled with water it impregnates the liquor with the smell, but gives no appearance of oil. If chewed, it proves tenacious, and neither mingles with the saliva, nor discovers any peculiar taste. By a mixture of gum arabic in fine powder it is rendered soluble in water; the wax requires its weight of the powdered gum for this end; and thus prepared, it is still insipid, and void of all acrimony. The addition of soap renders it also soluble in watery fluids.

Dioscorides observes that wax is healing and softening. When made into an emulsion, or mixed with spermaceti, in an electuary, or divided by rubbing it with the testaceous powders while it is in a melted state, it is successfully used to blunt the acrimony in diarrhœas and dysenteries; it supplies the loss of mucus in the bowels, and heals their excoriations.

With soap, to which a small proportion of opium is added, or a few grains of Dover's powder, it becomes an excellent remedy for diarrhœas of long continuance, and for dysenteries, when all obstruction and indurated fœces are removed. We have seen that it was formerly added to the vitrum antimonii, to mitigate its too great acrimony. Poerner used it in complaints of the bowels, by melting it with some fixed oil, and then combining it with water in an emulsion; but its union with soap, in pills, is preferable.

The college of Edinburgh gave the following preparation, in a former edition of their Pharmacopœia. Pu'LVIS TESTA'CEOUS CER'ATUS. *Testaceous cerated powder*.—Melt yellow wax over a gentle fire, and carefully stir into it, by degrees, as much of the compound powder of crabs' claws as the wax will take up. The dose is a drachm twice a day.

The chief uses of wax are at present in plasters, ointments, and cerates, partly to give them consistence, and partly to increase their emollient and suppurating quality.

The college of physicians of London order an EM-PLASTRUM CERÆ *plaster of wax*, formerly called *emplastrum attrahens*, to be made of yellow wax and sheep's suet prepared, of each three pounds; yellow resin, one pound; melted together, and the mixture to be strained whilst it remains in its fluid state. Ph. Lond. 1788. Though blisters used to be dressed with this plaster, it is not an agreeable form: softer and less adhesive cerates are preferable: the ceratum spermatis ceti, or the ceratum resinæ flavæ, are good substitutes for this plaster; which see, under CERATUM ALBUM et CITRINUM.

O'LEUM CE'RÆ; OIL OF WAX; called also *cerelæum*, from *cera*, and *ελαιον*, *oleum*, from being thinner than cerate, which is, in fact, the butter of wax, prepared by filling the upper part of the retort with fine sand, and distilling the wax through the sand.—Cut yellow wax in small pieces, and put as much into a retort as will fill nearly one half; then add as much clean white sand as will nearly fill the retort; after which place it in a sand furnace. At first an acid liquor arises, afterwards a thick oil, which sticks in the neck of the retort, unless it be heated by applying a live coal. The thick oil is also called the *butter of wax*, and may be rectified into a thin oil by distilling it several times, without addition, in a sand heat: if it is thus rectified it never hardens again.

Boerhaave highly extols this oil as an emollient, and for healing chaps and roughness of the skin, for curing chilblains, and, with the assistance of exercise, for relaxing contracted tendons. It is rarely used on account of its empyreumatic smell, but it is wholly free from acrimony.

CE'RA A'LEA, WHITE WAX, is the yellow wax artificially deprived of its colour, by reducing it into thin flakes, exposing them to the sun and air, and occasionally sprinkling them with water. When sufficiently whitened, it is melted and cast into thin cakes. Some whiten it first by dissolving it in hot water, forcing it through linen strainers into shallow metalline moulds, and then exposing it to the air. When wax is thus robbed of its colour, it has a less resolvent quality; but is altered in no other respect. It is sometimes adulterated with white oxide of lead, sometimes with tallow. Melting will discover the first, and the smell detect the other fraud.

The college of physicians of London give the following form for making the UNGUENTUM CERÆ, *ointment of wax*; formerly called *unguentum album*. Take of white wax, four ounces; spermaceti, three ounces; olive oil, a pint: let these be melted over a gentle fire, constantly and quickly stirring the compound until it grows cold. Ph. Lond. 1788.

The *céræ unguentum cum hydrargyro* is highly recommended in languid ulcers, and, as it acts favourably on the callous edges, it should be extended some distance round the sore. It consists of eight ounces of wax, and two of axunge, with six ounces of unguent. hydrargyri.

A few drops of rectified spirit of wine renders wax more easily pulverisable. See Lewis's Mat. Med. Neumann's Chem. Works.

CE'RA DICA'RDO. See CARDUUS PINEA.

CE'RA CINNAMO'MI. See CINNAMOMUM.

CERÆ'Æ, (from *κερας*, a horn, called also *Girri*). So Rufus Ephesius calls the cornua of the uterus.

CERA'MIUM. A Greek measure of nine gallons.

CERANI'TES, (from *κεραιννμι*, to temper together). See TROCHISCI.

CERA'NTHEMUS, (from *κηρος*, wax, and *ανθεμος*, a flower; so called because it is collected from flowers). See PROPOLIS.

CERASIA'TUM, (from *cerasus*, a cherry). A purging medicine in Libavius; so called because the juice of cherries is an ingredient.

CERA'SIOS, (from the same cause). The name of two ointments in Mesue.

CERA'SMA, (from *κεραιννμι*, to mix). A mixture of cold and warm water, when the warm is poured into the cold.

CERASO'RUM NIGRO'RUM A'QUA. See AMYGDALÆ AMARÆ.

CERASUS. The CHERRY-TREE. It receives its name from *Cerasis*, or *Cerasante*, a city of Pontus, from whence it was imported to Rome by Lucullus, and thence, according to Pliny, propagated into Britain.

Cherries have the same general properties as other summer fruits: they are agreeable, cooling, and quench thirst; and because they keep the body open they are termed EUCOILIA.

CERA'SUS, *ävium nigra*. See LAURO CERASUS et PADUS.

CERA'SUS AMERICA'NA. See MALPHIGIA.

CERA'SUS DU'LCEIS IN'DICA. See CAPOLIN.

CERA'SUS A'CIDA NIGRICA'NS, the MORELLO CHERRY.

CERA'SUS RU'BRA, SATI'VA, or ANGLI'CA; COMMON RED CHERRY.

CERA'SUS NI'GRA, also *cérasmus major*, BLACK CHERRY.

CERA'TIA, CERA'TIUM, and CERA'TONIA, (from *κερας*, a horn, which its fruit is supposed to resemble). See SILIQUA DULCIS.

CERA'TIA DIPHY'LLUS. See COURBARIL.

CERAT'ITIS, (from *κερας*, a horn). See UNICORNU.

CERATO-CE'PHALUS, (from *κερας*, cornu, and *κεφαλη*, caput; from the horn-like appearance of its top). See ACME'LLA and BIDE'NS.

CERATO-GLO'SSI, (from *κερας*, a horn, and *γλωσσα*, a tongue; muscles so named from their shape and insertion into the tongue). See HYO-GLOSSUS.

CERATO-HYOIDE'US, (from the *os hyoides*). See STYO-HYOIDES.

CERATO-PHARYNGE'US MA'JOR et MI'NOR. See HYOPHARYNGEUS.

CERATOI'DES, (from *κερας*, the genitive case of *κερας*, a horn). See CORNEA.

CERATOMALA'GMA, (from *κηρος*, wax, and *μαλγαμα*, a mixture). See CERATUM.

CERA'TUM, from *cera*, wax). CERATE; called also CERELÆUM (which see), *ceroma*, *ceronium*, *cerotum*, *ceratomalagma*. Cerates chiefly differ from plasters in consistence, being a softer kind of plaster, or harder kind of ointment. Their consistence is very convenient: when mercury is made up in plasters, a sufficient quantity is not absorbed from them to produce any very certain effect; but in a cerate it is resolvent and discutient, and when thus applied to venereal tophi and nodes, they often yield to it. The general rule for cerate is, eight parts of oil, fat, or juices, four of wax, and one or two of powder: or three ounces of oil, half an ounce of wax, and two or three drachms of powder. The London college directs the *ceratum album* to be made, of olive oil, four ounces by measure; of white wax, two ounces in weight; of spermaceti, half an ounce in weight: these must be melted and stirred together till the cerate is quite cold.

CERA'TUM ANTIMO'NII VI'TRUM. See ANTIMONIUM.

CERA'TUM LYTHA'RGYRI. See LITHARGYRUM.

CERA'TUM HYDRA'RGYRI NITRA'TI. See MERCUR. PRÆCIPIT. RUB.

CERA'TUM ME'LLIS. See MEL.

CERA'TUM CITRI'NUM.—Take of the ointment of yellow resin, half a pound; of yellow wax, one ounce: melt them together. Ph. Lond. 1788.

CERA'TUM RU'BRUM. RED CERATE. Take yellow wax, and sheep's suet, of each two pounds: red sulphurated quicksilver, fifteen grains: yellow resin, two ounces. Melt the resin, wax, and suet together, and afterwards add the sulphurated quicksilver; this is a cheap cerate for external dressings.

CERA'TUM EPULO'TICUM. See CALAMINARIS LAPIS.

CERA'TUM LITHA'RGYRI ACETA'TI. See LYTHARGYRUM.

CERA'TUM SAPO'NIS. See SAPO.

CERA'TUM CANTHA'RIDES, et HYDRARGYRI. Cerate of SPANISH FLY. See CANTHARIDES, and ARGENTUM VIVUM.

CERAUNO-CHRY'SOS, (from *χεραινος*, *thunder*, and *χρυσος*, *aurum*; so called from the violence of its explosion when heated). See AURUM FULMINANS, under AURUM.

CERBERUS TRI'CEPS. A powder composed of three capital active ingredients. See SCAMMONII PULV. COMPOSIT. under SCAMMONIUM.

CER'CHNOS, and CER'CHNON, (from *κέρχω*, *to wheeze*). See RHENCHOS.

CERCHO'DES, (from the same). See DASYS.

CER'RCIS, (from *κέρκισ*, *a pestle for a mortar, or spoke for a wheel*). See SILIQUASTRUM and RADIUS.

CERCO'SIS, *κερκωσις*, (from *κέρκος*, *a tail*). A disease of the clitoris, when it is enlarged and hangs like a tail from the vagina. See CLITORIS.

CER'EA, (from *cera*, *wax*). See CERUMEN AURIS.

CEREA'LIA, (from *ceres*, *corn*). All sorts of corn of which bread is made. The Greeks use the word *demetrias* in the same sense. Not to enlarge too far the article of bread, we referred to this part of our work a short view of the comparative qualities of different corn employed as its basis. The cerealia, strictly speaking, are the barley (*hordeum distichum* Lin.); the rye (*secale cereale*); millet (*panicum miliaceum*); the oat (*avena sativa*); wheat (*tritium hybernum*); rice (*oryza sativa*); and maize (*zea mays*). To these are sometimes added the buck wheat, from different species of fagopyrum; Guinea corn (*holchus sorgum*); flote fescue grass, or manna seeds (*festuca fluitans*); and the lotus, described by Mungo Park, (*rhamnus lotus*).

These different cerealia are set down nearly in the order of their nutritious qualities, beginning with the least nourishing; and, as these perhaps depend on the proportion of oil, their ascendency, and the easy evolution of their saccharine principle, are not very different. The buck wheat, the Guinea corn, the manna seeds, and those of the lotus, are truly saccharine. See ALIMENT, and the different articles under their proper terms: FARINACEA and BREAD.

"CEREBE'LLUM, and CERE'BRUM, (a dim. of *cerebrum*), as it were, the LITTLE BRAIN; called also *epencranis* *parencephalis* *en Cranion*.

"The *cerebrum* and *cerebellum* together are often called *cerebellum*, when the brain is spoken of in small animals, as birds, pigs, &c.

"The *cerebellum* is flattened, and convex on its upper and lower part; its greatest extent is from side to side.

VOL. I.

It is situated under the posterior lobes of the cerebrum, and divided into two lobes by a small process of the dura mater, which is a continuation of the falx running in its direction. It is covered by the pia mater like the cerebrum; but the lobuli of the cerebellum differ from those of the cerebrum, mostly lying horizontal. It hath no convolutions like the cerebrum, but it hath curved parallel lines described on its surface by the pia mater, and is of a darker colour than the cerebrum. It is composed of a cortical substance, and a medullary part like the cerebrum, but disposed in a more regular manner; and a perpendicular section of it hath a beautiful appearance, ramified like a tree, called *vitæ arbor*, the trunks of which form the pedunculi of the cerebellum. On the back part of the isthmus which joins the cerebrum and cerebellum we see four eminences; the two upper are called *nates* or *glutiæ*, and the two lower *testes* or *didymi*. Before these the aqueduct runs down into the fourth ventricle, the medullary covering of which is called *valvula magna Sylvi*. The fourth ventricle is placed between the cerebellum and the medulla oblongata."

"CE'REBRUM, (quasi *carabrum*, *ἀκαρα*, *caput*). The BRAIN, called *encephalus*: see also EPISPHERIA. Metaphorically called *emporium* (a Latin term for a market town), because it is the seat of all rational and sensitive transactions. Its structure and use are not so fully known as some other parts of the body, and different authors consider it in various manners. However, according to the observations of those most famed for their accuracy in anatomical enquiries, its general structure is thus described.

"The whole mass of brain is divided into CEREBRUM and CEREPELLUM. It consists of two substances, viz. one cortical or cineritious; the other medullary. The first is of an ash colour, the second is white, and of a firmer texture: they both are vascular, but the cortical is more so than the medullary, from whence the nerves proceed. When the two hemispheres of the cerebrum, each side of the falx being called an hemisphere, are removed, a white part, called CORPUS CALLOSUM, running from one hemisphere to the other, appears. The CENTRUM OVALE is the appearance of a particular section of it. The anterior ventricles are two oblong bodies placed one on each side the corpus callosum, with a partition between them, called the SEPTUM LUCIDUM, which is a continuation of the medullary substance of the corpus callosum. There is commonly much water in these ventricles, in those who die of disorders in their heads, as in the epilepsy, hydrocephalus, &c. but naturally they only contain about two drachms. In watery heads the fluid is always found in the cerebrum only; the cerebellum never hath any share in it. Each ventricle at the posterior part throws back an appendage, which makes a cavity in the posterior lobe of the cerebrum. Below the septum lucidum appears the FORNIX, or LYRA, with the *corpora fimbriata*, narrow at the anterior extremity, where it rises by a double basis called its CRURA, which follow the track of the ventricle; in each ventricle are eminences of a cineritious colour, called CORPORA STRIATA. The PLEXUS CHOROIDES, called also *reticularis*, or *retiformis*, is a plexus of vessels which follow the sweep of the ventricle: it is formed by the vessels of the pia mater; it is partly collected in

S F.

two loose fasciculi, which lie one in each lateral ventricle, and partly expanded over the neighbouring parts, and covering in a particular manner the thalami nervorum opti-*corum*, GLANDULA PINEALIS, and other adjacent parts, both of the cerebrum and cerebellum, to all which it adheres. The parts of this plexus, which are in the ventricles, contain some very small glands, which are considerably increased in some diseases. After the fornix is removed, we see a large plexus of vessels, particularly Galen's great vein, which go to form the TORCULAR HEROPHILLI, or fourth sinus, called also *lecheneos*, and, by Herophilus, *tenos*. It is a sinus formed by the meeting of the sinuses of the dura mater. Under the plexus, before the united thalami nervorum opti-*corum*, is a hole on each side called the ANUS and the VULVA; the latter goes to the infundibulum, the former to the aqueduct and third ventricle. The THALAMI NERVORUM OPTICORUM are white externally, and grey within, and are little eminences from whence the optic nerves arise. The third ventricle is very small; it runs back under the two thalami, between them and the medulla oblongata. The PINEALIS GLANDULA, pineal gland, called also *conarium*, *conoidea et conoidea corpus*, from its cone like form; and *turbinata*, covered by the plexus choroides, and situated on the sella turcica of the os sphenoides, is a little greyish body, the size of a pea: it lies just a little before where the transverse and longitudinal processes meet, where the vessels go to form the torcular. It is covered by the pia mater, and is connected by a little bone to each thalamus nervi optici.

"Numberless experiments prove, that the nerves are necessary to life; and that when the brain, or *medulla spinalis*, is much injured, life is at an end, or at least health: yet no part of the brain being injured, immediate death may ensue from different causes, though an injury of the *medulla oblongata* is so instantly fatal.

"Behind the infundibulum called *pelvis*, is seen the CORPORA ALBICANTIA, or GLANDULÆ WILLISII.

"Two glands are said to be in the brain, viz. the superior or *glandula pinealis*; and the inferior or *glandula pituitaria*, which see. They have the external appearance of glands, but as to their being such is not certainly known.

"The cerebrum fills all the upper portion of the cavity of the cranium, or the portion which lies above the transverse septum; each lateral half is divided into three eminences, called lobes; one anterior, one middle, and one posterior.

"The blood vessels which supply the cerebrum, cerebellum, and *medulla oblongata*, come partly from the carotid, and partly from the vertebral, arteries. The veins of the cerebrum and cerebellum may, in general, be looked on as branches not only of the longitudinal sinus of the dura mater, and of the two great lateral sinuses, but also of all the inferior sinuses of this membrane, in all which the veins terminate by different trunks."

"Plain truth," it is observed, "needs no flowers of speech," and we long hesitated whether this simple, this bald, unornamented description might not pass as plain sound science. If we could only add to it speculation, yet when this is the mode, a dictionary, which is to give the very body of the time its form and pressure, must admit of speculation. As the room it employed

was but small, and as it contained a text which might prevent repetition, we have, therefore, preserved it, and shall add the commentary.

A brain is the distinction of the more perfect animals, and its proportional bulk is the criterion of more perfect intellectual faculties. With a diminished brain, animals dwindle in the scale of intellect; and Camper's facial line, which marks the varying boundary between the most perfect human form and the meanest animal which possesses this distinguishing organ, depends on the bulk of the cerebrum. This is the part originally created; and the integuments, whether bony or membranous, are adapted to its primordial shape.

When the head is opened, and the tense DURA MATER removed (*vide in verbo*), we perceive a bluish white mass, formed apparently of vermicular convolutions, variegated with vessels of a deeper blue. This mass is divided into two hemispheres, which fill the upper part of the head, and form the projection of the forehead. Between the hemispheres passes a membrane, called the falx; because, when separated, it resembles a scythe or reaping hook; and these are united below the falx by a white substance, firmer than the brain, which has been just styled *corpus callosum*. This hard substance is continued downwards, and divides two ventricles; but as it is there thinner, it has obtained the name of *septum lucidum*. This corpus callosum, continued backward, connects the cerebrum and cerebellum; and as when cut through in a horizontal direction it appears of an oval shape, it has been called the *centrum ovale*.

When the base of a skull is examined, it appears to have numerous projections and depressions, adapted to the cavities or reliefs of the brain which rests on it. Behind are two spherical cavities, which contain the cerebellum; and between them is a hole, through which the medulla spinalis passes out, or, according to modern speculators, enters. We need not enlarge further on these projections, as our predecessors have given their appellations, except to add, that the pineal gland seated in the midst, on a kind of throne, the sella turcica of the sphenoidal bone, the only part to which no other corresponds, has been styled the seat of the soul. Less eccentric observers have supposed it to be a conglobate gland; but as we have found it the seat of calculous concretions, we must consider it as a secretory organ, whatever fluid it may furnish. To this subject, however, we shall return.

When the brain is examined more nearly we find a very thin membrane, called the pia mater, which accompanies the convolutions, and sinks into the interstices. This membrane, which will be afterwards described, conveys the blood vessels to the cineritious part of the cerebrum, and is itself covered with a cobweb-like membrane, which, however, does not follow it into the sulci, called *tunica arachnoides*. When we cut into the substance of the brain, we shall find for a little space within a brown substance, called, without any strict accuracy, the cineritious portion; which follows all the sulci of the convolutions, terminating in lines or rounded points, as directed by these. To this portion the medulla is united, and neither encroach on the other, but in the angles of the sulci: the depth of the cineritious portion is generally uniform. The colour is derived from very minute blood vessels; for, strictly speaking, the medullary part suffers vessels only to pass

through it. Those apparently dispersed on it, form such conspicuous streaks, as prevent us from thinking that the medulla contributes any thing further than a support: there is certainly no such minute distribution as generally attends any glandular apparatus, or distinguishes any organ destined for an important purpose.

This cineritious portion is certainly designed for an office of the greatest consequence; for we shall find that whatever be the proportion of the brain, it is always present, and by no means in the ratio of the medulla; and in parts where seemingly additional nervous power is required, in the course of the nerves, adventitious ash coloured matter is observed. In the substance of the brain, striæ of a cineritious hue are found; and some projections wholly consist of it, with different tints, while others contain this matter surrounded with, instead of containing, the medullary substance.

Near the origin of each pair of nerves we are informed that a brown substance is observable; and in the cerebellum, confessedly the most important part of the contents of the skull, it penetrates so deeply as to form by much the larger portion of it. Nature, also, seems to have supplied it with its blood, by means so refined as to prevent almost the possibility of its being wholly destitute; for not only does it receive arteries from the external surface, but other vessels pass through the base of the skull and penetrate the medullary substance to prevent any deficiency from accident. It is these arteries only, in our opinion, which we see in the medulla. It has been doubted whether the whole of this substance is vascular: the minutest injections do not penetrate every part; nor, perhaps, were the whole vascular, could this be expected.

The medullary substance is a pulpy mass; though probably, could our sight be sufficiently assisted, we should find it fibrous, since this structure appears where the nerves are sent off, when they assume their coat from the pia mater. Various communications are observable in the medulla, from the front to the hinder part, and from side to side. In a negro the medulla is yellowish, and sometimes a blackish yellow, though in the European of a pure white. In the former the yellow hue disappears by the access of the air. The corpora striata, and the thalami nervorum opticorum, which are in an European of a flesh colour, approaching a cineritious, are in the negro of a dusky brown, like the bark of a tree.

The ventricles of the brain are four in number. Two are on each side of an oblong form, projecting in what are styled horns; and it seems as if the medulla, growing more dense in the corpus callosum and septum lucidum, had proportionally contracted, leaving these cavities. In health they are probably distended by an halitus; but after death their parietes collapse, and a small portion of fluid is only discoverable. Two, as we have said, are on each side; the third is more forward and in front, below the fornix, or that portion of the medulla which forms the base, and in part, the sides of the lateral ventricles. It is a sulcus or slit of very inconsiderable dimensions, and scarcely merits the name of a cavity, but from it passes a canal of soft cineritious matter, styled the *infundibulum*, to the pineal gland. The fourth ventricle is in a perpendicular direction, anterior to the cerebellum. It is probable that all the ventricles communicate. Dr. Monro has, with much

anxiety as a discovery of importance, claimed the honour of having first described an opening between the lateral ventricles, and consequently a communication between the three former. Yet it seems that this communication which we have ourselves often traced, is not always found.

When we contemplate the ventricles, we seem to think that, like the chambers in the Egyptian pyramid, they are so disproportioned to the bulk that they can probably be of little advantage, and seem, as we have hinted, to be accidental. A more attentive examination, however, shows the fallacy of this conclusion; and they appear formed by design, and with a judgment so subtle or refined, as to elude our research. The pia mater from the basis of the skull, is conveyed as a lining round the parietes of each; and if the cineritious matter is an important organ, the pia mater, from which it originates, must be equally so. Again: the base of the brain is diversified by numerous projections, evidently designed to increase the surface, and afford a larger scope for the cineritious matter which we find in different parts, and chiefly about the origin of the nerves, which spring from the base. This cineritious substance is also found in many parts of the different ventricles; and in these too, we find plexuses of vessels so minutely convoluted, as probably to subserve some important purpose. Let us add, that any suppuration or any disorder on the base of the brain, soon produces the most alarming and fatal symptoms; while some spoonfulls of the medullary substance of the hemispheres may be discharged from a wound, without apparent injury to the intellectual faculties. We forgot to mention that the commissuræ, the medullary cords, which unite the different parts of the brain, are by far more common at the base of the skull than in any other part; nor is a circumstance wholly to be overlooked, that the *infundibulum*, which passes from the ventricles, terminates in the pineal gland: an organ probably of considerable importance, though its office is yet unknown. The *infundibulum* is not indeed hollow through its whole length, yet it seems to be occasionally so, as some authors have described the aperture as continued to the gland. Its uniform direction, and the small space occupied by the loosely textured medulla, seem to show the probability of some communication.

Anatomists have described, with great precision, all the minuter projections, cavities scarcely discernible, medullary cords of connection (commissuræ), and numerous sulci. To follow them would be useless; for this work is not designed to teach the minuter branches of anatomy, and the reader may think that we have already been unnecessarily minute. Yet we thought it right to give a particular outline of the anatomy of the brain; and we think we have not trespassed in descriptions which will not admit of some application.

The projecting and upper parts of the skull are filled with the two hemispheres of the cerebrum which rest on a membrane, a prolongation of the dura mater, styled tentorium. Below it is the cerebellum, whose connections we shall next describe. From each side of the brain, near the middle, medullary processes arise; and passing downwards and backwards, form what are styled the *crura cerebri*: these unite at an acute angle, and form what is styled the *pons varolii* or *tuber annulare*. From hence, what are styled the *crura cerebelli*

arise; or to the tuber they descend. A prolongation of the latter forms the medulla oblongata; which, when it escapes from the head, is styled the medulla spinalis. In the whole of this part of the brain, the striated or cineritious matter is freely united with the medullary; and at the union of the crura there are some protuberances, which, from their shape and colour, have obtained the names of corpora pyramidalia and olivaria.

As an appendage to the system of the brain, or rather as a detached nervous apparatus of considerable importance, we shall shortly describe the course and formation of the great sympathetic or intercostal nerve; the brain of the vital and involuntary motions, its succedaneum in the lower classes of animals, and, indeed, in human monsters where the brain is absent.

The great intercostal is styled a portion of the sixth pair of nerves, another portion of which is distributed to the muscles of the eye. It is, however, more properly a nerve from the medulla spinalis, and is sent rather to the brain, than proceeds from it. This we collect from the parts to which it is distributed being wholly independent of the will; and from the nerve between the neck, and that part where the nerves of the muscles of the eye are sent off, being larger than that between the brain and the same point. This almost insulated, nearly independent, nervous system, is connected with the brain, not only by this branch, but by a slight twig from the fifth pair; but its substance is formed by branches from all the different vertebræ. As soon as it appears in the neck it forms a ganglion, a medullary enlargement, in which the different filaments are intermixed, with generally the addition of some cineritious substance. In the neck only, there are three of these ganglia, to which nerves from almost every vertebra can be traced. In the chest it receives additional nerves, forming several smaller ganglia. From hence it escapes with the aorta, and reaches the sacrum; forming, with the branches from the spinal marrow of that part, other ganglia. It then turns inward; and at the hollow of the os coccygis, meets its fellow from the opposite side, which has traced the same course with similar additions.

When not united in a hard body like a ganglion, smaller nerves are often intermixed, and form, by their mutual decussation, a net work. In these a similar interchange of fibres seemingly takes place; and, in the course of the intercostal nerve through the trunk, nine distinguished plexuses have been described. To illustrate the advantages of this arrangement, we may now, though not in its proper place, remark that if an organ essential to life was supplied by one nerve, any injury to that, either in its origin or course, would be fatal. If, by uniting in a ganglion or a plexus with another nerve the fibres of both are intermixed, the injury to one nerve would be attended only with half the injury to the function of the organ, but the chance of injury would be increased in the same proportion. If, then, fifty nerves are mixed, the chances of injury are augmented, but the real injury to the organ is very inconsiderable. In this way has nature guarded those organs on which life depends; and we see that animal life may exist with a very small brain, or without any. But, after a perfect animal has existed, such is the connection of excitability through the whole nervous system, that, independent of the loss of blood, the destruc-

tion of the brain must destroy the excitability in the nerves. It may be diminished to a very inconsiderable degree; and, by the arrangement described, life may for a time be continued till the cause is removed.

The great sympathetic nerve is also the connecting link, between the two parts of which the human body consists. All our organs are doubled; and one half may be diseased or dead, with a partial injury only to the vital organs; and, in the first case, if the brain is not affected, without any apparent inconvenience to the unaffected parts. The great sympathetic, we shall find, supplies, in a great degree, the lungs, the heart, the stomach and intestines, the urinary and genital organs. The action of these, it must be obvious, are too important to be entrusted to the influence of one or several nerves: they must be raised above common accident: and, above all, must be independent of the will.

Such is the substance of the descriptions of the most correct anatomists; and we should now proceed to consider the functions of this organ, if we did not find it necessary to attend to the doctrines of an author who has begun to excite considerable attention on the continent; we mean Dr. Gall of Vienna. Dr. Gall has published no account of his system, and the substance must be collected from the reports of his pupils. We have now before us two, the one by Dr. Arnemann, and the other by M. Boisjames (*Journal de Physique*, vol. 55.), in which there is a view of the *cranium*, where the different organs are distinctly marked. Our chief object, at present, is his account of the brain and medulla spinalis.

We laid the foundation for this explanation very early, by inserting the arrangement of the animal kingdom by M. Virey (see *ANIMAL*). In this scheme, animals are distinguished as possessing a cerebral and intercostal, or sympathetic system: an intercostal system alone; or separate nerves with nervous molecules only. Dr. Gall considers the lower classes of animals as possessing nervous filaments only; the next, a spinal marrow; the superior animals possess a double spinal marrow; and the more perfect, a brain. In this last class, the spinal marrow, he thinks, exclusively forms the brain, and all the other nerves. The eight pair of nerves, supposed to arise from the brain, are derived, therefore, by Dr. Gall, from the spinal marrow, and seem to become a part of the brain before they are sent off in separate bundles. In this rank, the first are the *nervus accessorius*, and *nervus oculo motorius*; the common ganglion of which is supposed to be the *corpus olivare*, at the upper part of the medulla oblongata. Nearer the centre of the medulla are the nerves of the cerebellum; those medullary processes formerly supposed to be sent from the latter to the former: the ganglion of these is a substance situated in the body of the cerebellum, called, by anatomists, *corpus ciliare*.

The corpora pyramidalia, which we have mentioned as protuberances on the medulla oblongata, are supposed, by Dr. Gall, to be the origin of the cerebrum; for he expressly remarks, that the size of the hemispheres is always proportional to that of the pyramidal bodies. The ganglia of the pyramids are the *pons varolii*; and a part we omitted to mention, the ganglion *cerebri*, near the *fossa sylvii*. These nervous

strings are distinctly marked at the base of the skull by gyrating lines.

As eight pair of nerves, according to Gall, are derived from the spinal marrow, they are styled "entering nerves;" but there are some minute nervous filaments, *returning from the brain*, which he calls "retrograde nerves." These, he thinks, arise from the cortical substance which surrounds the ends of the first species of entering nerves. They unite in their course towards the spinal marrow, and increase in bulk, without passing through any ganglia. These nerves, in his opinion, form commissuræ. Thus the commissuræ of the retrograde acoustic nerve is situated under and behind the pons varolii; that of the olfactory nerve between the ganglion belonging to these nerves; that of the retrograde nerves of the cerebellum in the pons varolii itself. The commissuræ of the retrograde nerves of the cerebellum are the corpus callosum, the commissura anterior of the lobe of the brain, near the optic nerves, continued in the septum lucidum, &c. Through the very middle of the spinal marrow, to a raphe or seam on the top of the corpus callosum, a very delicate medullary substance is observed to ascend, which Dr. Gall considers as the uniting medium of the double system of organs in the animal machine; an office we have assigned to the great intercostal.

It will be obvious on examining this system, that little difference can arise in any disquisition respecting the functions of the brain, whether it be derived from the spinal marrow or the contrary; and, ascending from the more simple structure, we may as well suppose a cerebral organ *added*, as, in descending, to view the lower animals deprived of it. The brain, we find, is not essential to animal life; for the nerves subservient to it are derived from another source; and it is certain, that a wound in the spinal marrow is more fatal than one in the brain. The functions of the latter, as we have seen, may be destroyed, while those of the former remain. So far, perhaps, the balance may be said to turn in favour of Dr. Gall. The brain, however, is the chief seat of the intellectual functions; and this is acknowledged by our author, since, in his "Organology" he has assigned to its different parts various passions and propensities. We have already admitted his chief position, that the shape of the cerebrum and cerebellum determine that of the skull; and, as he has found (or thinks he has found) certain projections connected in man and different animals, with different propensities or passions, he has denominated these their seat. He seems to have carried this enquiry to a considerable extent; and his collection of skulls, or casts, is said to be numerous and highly curious, as they belonged to characters the most notorious, of very different descriptions. On a careful examination and consideration of this system, we cannot think it wholly fanciful, though fancy seems often to predominate. But this is from our present subject. We shall return, however, to Dr. Gall's system, with some notice of that of Lavater, under the article CRANIOLOGY.

We must not conclude this descriptive part of the cerebrum, without some notice of the enquiries of Camper. This very accurate anatomist examined, with peculiar and discriminated attention, the skulls of different races of mankind; and found that the *facial line*, viz. the direction of a ruler applied to the lips and fore-

head, distinguished the more perfect and beautiful forms, from those confessedly less generally pleasing. The line of the faces of the ancient heads formed, with a horizontal line, an angle of  $100^{\circ}$ ; beyond that is the deformity of the hydrocephalus; between it and  $70^{\circ}$  the usual European forms: a less angle than  $70^{\circ}$  marks the Calmuc, the negro, the ape, the dog, and the woodcock, in succession. In the last the angle is almost wholly lost. When we trace the forms of the different races of mankind in the natural history of man, we shall enlarge on this subject. It is only necessary at present to observe, that the direction of the facial line is marked by the projections of the hemispheres of the cerebrum, and the situation of the foramen occipitale. These distinguish the more perfect races; and, indeed, mankind, from its nearest resemblance, the ape.

The functions of the brain are so singular and important, that every art has been employed to trace its structure and component parts. When the knife of the anatomist had exhausted its dexterity, injections and microscopical observations came in aid. The cineritious matter, we have said, is vascular; but we added that the whole could not be injected. Some authors have thought that the whole has been filled; but this is not probable, nor supported by the experiments of the most accurate anatomists. Veins are traced from it, and their contents are conveyed to the sinuses. The parts not injected have been supposed, from microscopical observations, to be follicles; and small globular bodies have been discovered. But these are seen in almost every fluid of the human body, particularly in mucilaginous ones, and lead to no important consequence. The hemispheres of the cerebrum are chiefly mucilaginous; but as we approach the basis of the skull, a fibrous texture is more conspicuous: and, if the brain be macerated in acids, this fibrous structure can be traced further into its substance than by mere anatomical investigation. When the brain is boiled in oil, it assumes a granulated appearance.

The refinements of modern chemistry have also tortured this substance with as little profit. We recollect only the labours of M. Thouret, in the 38th volume of the *Journal de Physique*, p. 329, and M. Fourcroy's, in the 16th of the *Annales de Chimie*. The brain they found somewhat heavier than water; and consequently, a person at rest in a horizontal position in water, swims indeed, but with the head lower than the surface. A small proportion of saline matter was discovered by M. Fourcroy, but scarcely  $\frac{1}{130}$  part of the whole; and it consisted of phosphat of lime, of soda, and ammonia. In other respects the brain seemed essentially to differ from the other solid parts. It certainly contained little animal matter, and consisted chiefly of albumen; but the latter differed from that of the human body in general, or was changed in its properties by the mixture of another substance, whose nature has not been ascertained. It certainly is not an oily matter, and the brain is not a saponaceous substance. We strongly suspect that it contains sulphur; but much room remains for further investigation. M. Thouret considers it as analogous to spermaceti; and it is singular that, when kept from the air, it for a long time experiences little change.

After having detailed every important circumstance

relative to this very peculiar organ, we have not found a single property to assist us in explaining its functions. If we examine its changes from disease, we shall find no further assistance. In maniacal persons it is found sometimes hard and dry; in idiots, soft and mucilaginous. Occasionally an abscess appears at the basis, and sometimes the pineal gland is suppurated, or filled with calculous concretions. Although we think, with some authors of high credit, that the brain is always organically affected when any violent and permanent injury of its functions has preceded, yet there is no given change, from any particular series of symptoms. Dissection does not teach us any indication to pursue; nor would the powers, which we possess, probably enable us to fulfil them, if they were pointed out.

We must, therefore, consider the brain as the material organ of an immaterial principle, intimately united with it during life, and forming with it one distinct, inseparable whole. When we speak then of the actions and functions of the brain, we speak of it only as the instrument; nor can we after this declaration be misunderstood. Though we may sometimes employ the language of materialism, we consider the materialist, in general, as a weak, uninformed philosopher, and should deprecate being confounded with the herd.

The best physiologists suppose the brain to be fibrous; and when Gall calls it a membrane, he means no more. Fibres are conspicuous at its base, and in its prolongations, the nerves. These chords convey impressions of different kinds to the brain, in a manner which has occasioned many disputes. It was for a long time supposed that the brain was a gland which secreted a fine fluid, conveyed through the minute fibres of the nerves, which conducted to their origin the impressions received at their extremities; but the great tenuity of such a fluid, its rapid motions, and, above all, the little probability of the nervous fibres being hollow, rendered this system highly improbable. Yet, that the brain was a gland appeared to be a conclusion, obvious from its structure, its large supply of blood vessels, and their very minute convolutions. These facts appeared to Dr. Cullen in so striking a light, that, while he considered the nerves as vehicles of a very fine fluid, which was the cause of sensation and motion, he supposed that the brain secreted the nutritious particles designed to repair accidental losses, either from absorption or accidents; and that these were conveyed along the surfaces of the nerves. The improvements in electricity, and more lately in Galvanism, have given a different appearance to this question, which will soon claim our attention more particularly. We shall only at present state what we consider to be the nature and properties of the nervous power.

It is probable that in each nervous fibril, an elastic fluid is inherent, forming, from the first moment of animation, a part of it; differing, however, according to the state of the constitution, in power, in mobility, and, perhaps, in other qualities. Of this fluid the nerves are conductors; and they are surrounded in their course by non-conducting membranes; while the same membrane lines every part of the brain, and is carried into the deepest cavities, guarding with particular attention the slightest aperture. In this view the

sanguiferous vessels are chiefly useful in nourishing this medullary substance; and they appear to be necessary also in adapting the nerves to their office; for when the circulation is greatly increased, the sensibility is more acute; and when it languishes, or is destroyed, the nervous energy soon shares the same fate.

This fluid must be necessarily an elastic one; and impressions are apparently conveyed through it by vibrations. It does not follow from hence, that the nerves vibrate like musical chords; or that, in every the slightest motion, a portion is conveyed from the brain. The elasticity of the fluid is proved by the momentary continuance of the impression after the cause is removed; and vibration is a term employed in many branches of philosophy as a means of communicating motion, without any very distinct application. If we touch an object with a stick, or with a metallic rod, we perceive through it the impression, and, in a general way, the nature of the substance. The impression must be conveyed by something; and whatever, that something is, it may as well convey impressions through the nerves as through the rod. But, through the nerves only can it affect the brain, and produce an *idea*, or some change in the brain, or its fluid connected with the nature of the object, and which conveys to the mind some peculiar and discriminated impression which it afterwards retains.

We have offered these opinions, not indeed essentially different from those taught by Dr. Cullen, because it enlarges our sphere of language, and enables us more clearly to convey our own opinions. It is immaterial to the purpose whether this view be ultimately correct: it is sufficient that it meets all the phenomena already known, and carries us to the confines of immateriality; of which we can have no idea, while the organs which convey ideas are material. *We know of no ideas that are innate: all are derived from sensible objects; and even in dreams, when the mind seems to sport uncontrolled, the distorted, and often apparently new, images, will be found only heterogeneous compounds of sensible ideas formerly received.*

We can now, then, speak more fully of the functions of the brain, the seat of intellect, the receptacle of our ideas, and the scene of all the intellectual operations. Animal life, as we have said, is confined to the intercostal system, perhaps to the cerebellum; which, we own, appears to us rather an appendage to the medulla spinalis than to the cerebrum.

The most striking function of the brain is *volition*; and this, the great source of all our voluntary motions, is, we believe, always excited by sensation, though often by sensations wholly unperceived or unattended to. It is singular that we will the end only: the means are directed by mind, or in some cases by a necessary connection. In sneezing, in coughing, and yawning, volition appears imperfectly, if at all, exerted; and the motions excited appear to arise from a connection of nerves, though the means are directed with great precision to the end.

The great intellectual principle which pervades every intellectual function, the *association of ideas*, is also carried on in the brain; and it is this principle which seems to require that the receptacle of our ideas should be so large and extensive. We mean not to revive the old system of material vestiges as the effect of im-

pression, and the sensible prototypes of our ideas; but it involves no contradiction to suppose, that a nervous fibre, whose mobility has been once excited, will more readily yield to the same stimulus, when repeated in a less degree; and ideas once connected will, by the same increased mobility, be excited by any impression, mental or corporeal, on the neighbouring parts, as the voice involuntarily pursues the air which another has begun to sing. The variety of distinct impressions communicated to the mind through the medium of the nerves, necessarily, therefore, requires an extended bulk of the common sensorium; and, though a part of the cerebrum may be occasionally destroyed without apparent injury to any function, we need only reflect how few and simple are the ideas of the greater number of mankind, compared with those of Bacon, Newton, Boyle, or Locke. Yet we see, after a partial compression of the brain, some of the powers of mind greatly weakened; and it is singular that these powers are chiefly such as are concerned in succession, and consequently association; as in counting numbers, or pursuing any successive train of ideas.

It has been doubted, whether the mind can of itself commence a train of thought wholly new, or excite ideas different from those received through the senses. We have, as already observed, never been able to discover any such in all the wanderings of a morbidly excited imagination, all the reveries of fancy, all the eccentric images in dreams or low delirium: yet the mind can voluntarily again raise ideas formerly impressed; and this faculty is styled *reminiscence*, or *memory*: a power which is greatly assisted by association.

Though we consider mind as an immaterial principle, yet, as its instrument is the brain, the state of mind must often appear to partake of the diseases of the body: and the restoration of mind equally follows the returning health of body. The reason is, that we do not see the mind act but through the medium of the corporeal organs; and every agent will be powerful in proportion to the power of his means. We, therefore, in considering the effects of astringents, referred the change in the state of the nervous fluid to that of the solid; and so again in mental diseases we shall endeavour to show the connection of mental powers with the same fluid. In some instances the change is so sudden, that the fluid itself must be primarily affected, as in the attack of fevers; and the mind is weakened in proportion. This did not escape Shakspeare, who has described the effects of an ague fit with the spirit of a poet, and the precision of a philosopher. Speaking of Cæsar, Cassius says,

“ He had a fever when he was in Spain;  
And, when the fit was on him, I did mark  
How he did shake! ’Tis true, this god did shake:  
His coward lips did from their colour fly:  
And that same eye, whose bend doth awe the world,  
Did lose its lustre I did hear him groan;  
Aye; and that tongue of his, that bade the Romans  
Mark him, and write his speeches in their books,  
‘ Alas!’ it cried, ‘ Give me some drink, Titinius,’  
As a sick girl.”

This sudden change in the nervous energy, as evident in fevers, and in breathing noxious vapours, has been styled by Dr. Cullen “*collapse*,” and we shall

adopt the term more from shortness than any desire of connecting it with any real alteration, or as referring to any theory. Yet, as we know no instance in nature of a sensible fluid circulating with the rapidity of the nervous; and as we *do* know that a power not obvious to our senses, which possesses some of its peculiar properties, really exists, we perceive no theoretical temerity in adopting its terms. It extends, as we have said, the bounds of language; and facts expressed in this language may be without violence transferred to any other, when future discoveries may extend our knowledge of this mysterious power, whose cause we know not, but whose influence is general and extensive.

To penetrate further into the regions of metaphysics is not suitable to our present object. What we have now introduced, we shall have occasion hereafter to apply. We shall conclude this article with some more particular account of the circulation through the brain than the pages of Dr. Motherby and his associate have supplied. To connect the whole, a little repetition is unavoidable.

The course of the carotid arteries has been already explained; and the peculiarity in the circulation chiefly relates to the venous system. The veins are large and tortuous, unconnected with cellular substance, without valves; freely anastomosing, and terminating in reservoirs rather than in large trunks. The apparent great object of this apparatus is to confine a certain portion of blood in the head; and, at the risk of a morbid accumulation, to prevent the source of the nerves from wanting at any time a supply. Even respiration, as we shall find, contributes to the same purpose.

The mode in which the veins open into the sinuses confirm the same principle. We are informed by Vicq d’Azyr that they open in a direction opposite to the current of blood; and, though the universality of this distribution has been doubted, it is admitted that they very frequently penetrate obliquely through the coats of the sinus, as the ureters into the bladder; or that little valves occasionally cover their apertures; a structure which produces the same effects.

Where the veins penetrate the dura mater, this membrane and the pia mater are united by a fatty substance, which has been mistaken for the glands of Pacconius; but these are in the cavity of the longitudinal sinus, and act still further as valves, to save the arteries from the danger of being exhausted; since these glands are placed at the entrance of the vein into the sinus. The course of the smaller veins is circuitous, and with difficulty explained without numerous plates. We shall not attempt a description, for it admits of no application.

The arteries in the plexus choroides, which are peculiarly minute and tortuous, probably have an important office, which we cannot even conjecture. The veins are large which arise from them, and some are peculiarly conspicuous. The great central vein of the brain is styled, from Galen, who first described it, *vena Galeni*. From nearly the centre of the brain, this vein collecting all the blood, enters the fourth sinus, where it receives the blood from the inferior longitudinal sinus. But to be more distinct, we shall begin with the latter.

The great longitudinal sinus commences near the root of the nose, and runs backward close to the skull,

over the head, in the direction of the sagittal suture. The vena Galeni, running backward, forms the chord of this arc. At nearly two thirds from the front, to the occipital bone in this chord, the inferior longitudinal sinus descends to meet it, forming the fourth sinus. It descends in a curved line, not concentric with, or parallel to, the great longitudinal sinus, but nearly in the same direction; and in the prolongation of this chord, where it meets the longitudinal sinus near the occipital bone, the left and right lateral sinuses branch off, terminating in their respective jugulars, after a horizontal course of some length.

Nearly at the fore part of the base of the skull, below where the vena Galeni assumes a distinguished bulk, there are some other sinuses, irregular in their shape, and tortuous in their course, which terminate also in the jugulars.

The great sinus is formed by the splitting of the laminae of the dura mater, and as the separation is more distant above, the cavity of the sinus is triangular; the inferior lesser sinus runs along the edge of the falx, without any peculiar form; but the fourth sinus, which is continued along the tentorium, by the joint action of this membrane and the falx, is also drawn into a triangular shape. The other sinuses are apparently enlarged tortuous veins, which we need not particularly mention.

It is obvious from this description, that nature anxiously retains a portion of blood in the head, even at the risk, as we have said, of accidental accumulation. But she has not incurred this danger, without attempts to lessen or relieve it. Though the longitudinal and the occipital sinuses are bound by the dura mater and tentorium, the rest are free, and admit of dilatation. At the point of meeting the angle of the occipital bone, they are so closely tied down, that the ancients supposed the blood in this part subjected to a peculiar pressure, and the point of union was styled the torcular Herophili, from its discoverer. The inferior sinuses, however, have no such restrictions; and they communicate by veins, styled the emissariae of Santorinus, which communicate also with the external veins. Vicq. d'Azyr informs us, that those sinuses which lie near the orbits and ethmoidal bone, the orbitar and carvenous, anastomose by a number of small veins with the hinder veins of the nose; so that the advantages of critical hæmorrhages from the nose in relieving acute fevers where the head is affected, will be sufficiently obvious. But, though authors have described the emissaries of Santorinus with particular care as the source of relief in apoplexies, and similar disorders arising from accumulation, their bulk is by no means equal to this office; and they seem chiefly useful in preventing partial compression, from the too great fullness of any particular sinus.

The uses of the sinuses have been differently explained by former authors; and these cavities have been supposed reservoirs, to prevent any sudden interruption in the blood through the vena cava to the heart from pressing too strongly on the tender medullary organ. If this were, however, the case, they are adapted very imperfectly for the purpose, since they are closely tied down where dilatation might be safely allowed; and without any restriction in the base of the skull where their compression must necessarily be injurious. If it

be true that the nervous fibres require an active circulation for the support of their excitement, it must be an object of the highest importance that the arteries of the brain should not be suddenly emptied, or frequently liable to the accidents that may occasion it. This purpose the sinuses answer very completely; and, as we shall find, that during inspiration the course of the blood in the upper vena cava is obstructed, this function will appear to be an assistant in the same office.

See Winslow's Anatomy; Haller's Physiology; Willis' Anatomie Cerebri; Vicq. d'Azyr on Brain, and his Memoirs in the Academy of Sciences for 1781; Malacarne Encephalotomia Nuova; Monro on the Nervous System.

CE'REBRUM ELONGA'TUM. See MEDULLA SPINALIS.

CE'REBRI AFFE'CTIO SPASMO'DICO-EC'STATICA. See APOPLEXIA.

CE'REBRI COMPRES'SIO, and CONCUSSIO. COMPRES-SION OF THE BRAIN: (from *con*, and *premo*, to press together; and *con*, and *quatio*, to shake together).

This often happens from external injuries, and generally attended with giddiness, dimness of sight, coma, loss of voluntary motion, vomiting, an apoplectic ster-tor in breathing, convulsive tremors in different muscles, a dilated state of the pupil of the eye, even when exposed to a clear light; paralysis of different parts, especially of the side of the body opposite to that part of the head which has been injured; involuntary evacuation of the urine and fæces; an oppressed, and, in many cases, an irregular, pulse; and when the violence done to the head has been considerable, it is commonly attended with a discharge of blood from the nose, eyes, and ears. Some of the milder of these symptoms, such as vertigo, stupefaction, and a temporary loss of sensibility, are frequently induced by slight blows on the head; and as they often appear to be more the consequence of a shock, or concussion given to the substance of the brain, than of compression induced upon it, so they soon commonly disappear, either by the effects of rest alone, or some other gentle means. (See CONCUSSIO.) But when any of the other symptoms take place, such as convulsive tremors, dilatation of the pupils, involuntary passage of the urine and fæces, and especially when much blood is discharged from the mouth, nose, eyes, and ears, it is almost certain that much violence has been done to the brain, and that compression in some part is induced. In fine, a compression of the brain may be brought on by whatever contributes to diminish the cavity of the cranium, or increase its contents in any considerable degree: hence fractures, attended with depression of any part of its bones, forcible introduction of any extraneous body through both tables of the skull, the effusion of blood, serum, pus, or any other matter, the thickening of the bones of the head produced by lues venerea, collection of water in the ventricles, or other parts of the brain, may occasion this disease. For the cure of which see CONCUSSIO; FRACTURA CRANII; DEPRESSIO, EXTRA-VASATIO, HYDROCEPHALUS; also Bell's Surgery, vol. iii. p. 132, &c.

CE'REBRI BA'SIS. See PALATUM.

CE'REBRI GA'LEA. See CRANIUM.

CEREFO'LIUM, a corruption of CEROPHYLLUM. See CÆLIFOLIUM, and CHÆREFOLIUM.

CEREO'LIIUM HISPA'NICUM. See MYRRHIS.

CEREO'LIIUM SYLVE'STRE. See CHÆROPHYLLUM SYLVE'STRE.

CERELÆUM, (from *κερος*, *wax*, and *ελαιον*, *oleum*). See CERATUM et OLEUM CERÆ, under CERA.

CEREVI'SIA AMA'RA, and ANTISCORBU'TICA, (from *Ceres*,) as all ales are made of corn. See ALLA.

CEREVI'SLE CATAPLA'SMA. Into the grounds of strong beer stir as much oat meal as will make it of a suitable consistence. This is sometimes employed as a stimulant, and antiseptic to mortified parts.

CE'RIA, or CE'RIÆ, (from *cereus*, *soft taper*). See TANIE.

CERION, *κεριον*, a honey comb, (from *κερος*, *wax*). See ACHOR.

CERI'TUS, or CERRI'TUS, (from *Ceres*,) the disease arising from malt liquors.

CE'RNUIUS, (from *cernuo*, *to fall with the face downwards*). In botany it means bent downwards, drooping, hanging down its head.

CERO'MA, et CERO'NIUM. See CERATUM.

CEROPI'SSUS, (from *κερος*, *wax*, and *πισσα*, *pitch*). Also called *dropax*, *drophacismus*. A plaster of pitch and wax. It was usual to spread it on cloth or leather, and to apply it to some part of the body, then to pull it off again and apply it afresh, frequently renewing the application and removal, to induce a redness on the part and attract the fluids which nourish it. To render this plaster the more efficacious, acrimonious powders were added to it. This *dropax* was also used to make hair fall off, or to pull it off from any part. But the ingredients for the dropaces were pitch, oil, bitumen, galbanum, and other stimulants.

CERO'TUM, (from *κερος*, *wax*). See CERATUM.

CE'RRIO, (from *κερας*, *cornu*, because its wood is hard like horn). See PHELLODRYS.

CERU'MEN AU'RIS, (from *cera*, *wax*). The wax in the EARS. The Latins call it *cera*, *aurium sordes*, and *marmorata aurium*, *cyphisele*, *cyphselis*, *fugile*. It inviscates, and retains insects, and prevents their hurting the membrana tympani. It is a yellow, oily, bitter, and viscid fluid, which is inspissated by stagnation, softens by heat, and evaporates in a white smoke, whose odour resembles that of burning fat. By a continuance of the heat, it melts, swells, grows dark, and emits an ammoniacal and empyreumatic odour. It mixes with water, forming an emulsion, which, on putrefaction taking place, deposits white flakes. Alcohol dissolves more than half; and, when evaporated, a deep coloured substance remains, nearly resembling the resin of bile. What the alcohol does not dissolve appears to be albumen, which, when burnt, leaves marks of soda and phosphat of lime. Æther dissolves it, but the solution is less coloured; so that, added to these ingredients, it seems to contain a peculiar colouring principle. It is separated from the glands in the part of the ear in which it is found. It is fluid when first discharged, but soon thickens by stagnation. Wax, under some circumstances, occasions deafness. See SURDITAS.

CERU'SSA. So called because it was a pigment made by dissolving lead in vinegar, and formed of the consistence of wax; hence *κερος*, *κεροεις*, *κεροεσσα*,—undè *κερυσσα*. See PLUMBUM.

CERU'SSA ANTIMO'NI. See ANTIMONIUM.

VOL. I.

CERVA'RIA, and CERVA'RIA NI'GRA, (from *cervus*, a stag, because deer are fond of it). See LASERPITIUM VULGATICUS, et OREOSELINUM.

CERVI SPI'NA. See RHANNUUS.

CERVICA'LES, belonging to the neck, (from *cervix*, *the neck*,) the nerves which pass through the vertebræ of the neck.

The first *cervical nerve* throws out a considerable branch to the occiput; supporting, in some degree, the idea of Gall: it joins the ninth pair from the brain, to form the first *cervical-ganglion* of the intercostal.

The second *cervical nerve* hath a very remarkable plexus; it sends out a very considerable nerve to the occiput, as well as the first. It sends off three branches behind the sterno mastoideus, where they are entangled with the accessorius Willisii. The first branch, going upward and backward, becomes cutaneous on the posterior parts of the temporal and parietal bones. The second goes upward, and a little forward under the sterno mastoideus, and throws branches to the parotid gland, to the lobe, and to the posterior side of the ear. The third goes horizontally forward to the neck, and there becomes a cutaneous nerve, which is sometimes pricked in opening the external jugular vein.

The third *cervical nerve* goes downwards by a number of filaments towards the shoulders, and produces the phrenic nerve, which runs towards the thorax, before the anterior portion of the scalenus, between the subclavian artery and vein, contiguous to the trunk of the par vagum; passes down before the root of the lungs, follows the pericardium, and branches out in the diaphragm. That on the right is shorter than that on the left, as the latter goes round the apex of the heart.

The four inferior pairs, since a similar nerve arises on both sides, are larger than those already named. Their main trunk, with the first nerve of the back, passes between the portions of the scalenus over the first rib, into the axilla, where they produce six trunks, which go to the upper extremities. In their way thither they detach branches to all the arteries.

The first of these six branches is the HUMERA'LIS, which follows the course of the artery of that name, round the head of the os humeri.

The second is the CUTA'NEUS, which runs down the inside of the arm, and goes into the fore arm, just where we open the basilic vein, and is often wounded.

The third is called the MUSCULO CUTA'NEUS, and is larger. It rises pretty high, and throws branches into the coraco brachiaëus, through which the trunk passes obliquely; it is then covered by the biceps, and, passing through between the brachiaëus and biceps, it sends off several branches, and lies on the outside of the tendon of the last mentioned muscle, where we commonly bleed in the median cephalic vein.

The fourth is called CUBITA'LIS, or ULNA'RIS, the ulnar nerve; it follows the course of the artery, but passes gradually backwards, and gets behind the inner condyle of the os humeri, betwixt which and the olecranon it passes to the fore arm. A little above the carpus it divides into an anterior and posterior branch, which goes to the palm, the back of the hand, and fingers. See, under CUBITALIS, Cheselden's account.

The fifth branch, called MEDIA'NEUS, the median nerve, passes down contiguous to the brachial artery, and, accompanying the vessel, goes to the fore arm

and to the palm of the hand, thence to the thumb and fingers.

The sixth branch, called the *RADIA' LIS*, *radial nerve*, passes down the inside of the arm, and then backwards between the *brachiaëus externus*, and the short heads of the *biceps externus*, attended by the artery. When it hath got round, it runs down; and, at the head of the radius, it gives off a cutaneous branch, which goes to the thumb and fingers on the back of the hand, whilst the main trunk passes round the head of the radius through the *supinator radii brevis*, and goes betwixt the radius and ulna, to be lost in the *extensor digitorum communis*, and the muscles of the carpus and thumb.

*CERVICA' LES ARTE' RIE.* The *ARTERIES* of the NECK.

The *cervical artery* rises from the subclavian on its upper side, and is presently afterwards divided into two, which sometimes come out separately, and at others by a small common trunk; the anterior goes to the anterior muscles which move the neck and head, the posterior to the *scalenus*, *trapezius*, &c.

The *anterior cervicalis*, running behind the carotid of the same side, is distributed to the *musculus coraco-hyoidæus*, *mastoidæus*, *cutaneus*, *sterno-hyoidæus*, and *sterno-thyroidæus*, to the jugular gland, and *aspera arteria*; the muscles of the pharynx, bronchia, *œsophagus*, and to the anterior muscles, which move the neck and head. This artery has been observed to send out the *intercostalis superior*.

The *posterior cervicalis* arises sometimes a little after the *vertebralis*, and sometimes from that artery. It passes under the transverse apophysis of the last vertebra of the neck, and from thence runs up backward, in a winding course, on the vertebral muscles of the neck, and then returns in the same manner. It communicates with a descending branch of the occipital artery, and with another of the vertebral, about the second vertebra. It is distributed to the *musculi scaleni*, *angularis scapulæ*, and *trapezius*, and to the jugular glands and integuments.

*CERVICA' LES VENE.* The *CERVICAL VEINS*. They are branches from the upper external jugular veins, or from the vertebral veins: they spread in the vertebral muscles of the neck, and communicate with the *humeralis* and *occipitalis*.

*CERVICA' LIS DESCE' NDENS, DO' RSI.* See *SACRO LUMBARI ACCESSORIUS*.

*CERVICA' RIA*, (from *cervix*, the neck, so named because it was supposed to be efficacious in disorders of the neck and throat). *BELL FLOWER*, or *CAMPANULA*.

The flower consists of one petal or flower leaf, shaped like a bell: before it is blown it is of a pentagonal figure, and when fully opened it is cut into five segments at the top. The summit of the pedicle is expanded into an ovary, whose apex is crowned with a monophyllous quinquifid calyx, divided into five long segments. The seed vessel is for the most part divided into three cells, each having a hole at the bottom, by which the seed is emitted.

*Campanula esculenta.* SMALL OF GARDEN RAMPION. *Campanula rapunculus* Lin. Sp. Pl. 232.

The roots are used in salads.

*Medium, viola Mariana* Lin. Sp. Pl. 236. *Syrian BELL FLOWER*.

*Trachelium*, (from *τραχηλος*, the throat,) *campanula vulgarior major*. GREAT THROAT WORT, and *CANTERBURY BELLS*. *Campanula trachelium* Lin. Sp. Pl. 235.

The root is very moderately astringent.

*CERVICULÆ SPI'RITUS*, (from *cervus*, a stag) *Rulandus* gives this appellation to the spirit of the bone of a stag's heart.

*CE'RVIX*. Usually confined to the back part of the neck; hence derived by some from *curvus*, *crooked*; but, by others, quasi *cerebri via*, as the road leading to the brain; also *collum*, the NECK. This is applied figuratively to different parts; and there is the *cervix vesicæ*, *uteri*, *ossis*. (See *VESICA*, *UTERUS*, and *PROCESSUS*). But, in its general acceptation, it means that part of the body situated betwixt the head and breast.

The *neck* is divided into the anterior part or *throat*, and the posterior or *nape*. It contains the *larynx*, a part of the *trachea arteria*, the *pharynx*, part of the *œsophagus*, the *musculi cutanei*, *sterno-mastoidæi*, *sterno-hyoidæi*, *hyo-thyroides*, *coraco-hyoidæi*, *splenius*, *complexus*, the *musculi vertebrales*, which lie upon the first seven vertebrae, and a portion of the *medulla spinalis*.

The *ARTERIES* which go to the *neck*, are the *arteriæ carotides externæ*, et *internæ*, *vertebrales*, et *cervicales*. The *VEINS* are, the *venæ jugulares externæ* et *internæ*, *cervicales*, et *vertebrales*. The *NERVES* are, the *portio dura* of the auditory nerves, the eighth, ninth, and tenth pair, the seven cervical pairs, and the *nervi sympathetici maximi*.

A contraction of the neck to one side is among the disorders to which it is subject. *Tulpius* calls this contraction *CAPUT OBSTIPUM*; but it is a species of *contractura*: he hath removed this disorder in those who had exceeded their twentieth year, and were born with it: others have had the same success.

This disorder is usually described under the title of the *WRY NECK*. It proceeds from burns, a stricture in the skin, a relaxation of some of the muscles in the neck on one side, or a contraction of them on the other; but the most common cause is a contraction of the *mastoid* or *sterno-mastoid* muscle only.

If it depends on a paralysis on one side, the cure must depend on that of the disease: if from inflammation, external blisters and stimulants are employed. In general, *emollients* on the contracted part, and *stimulants* on the opposite, afford the most probable means of relief. Electrical sparks, drawn from the relaxed side, are also often useful; and the contracted muscle should be kept at its full extent of distention, by a bandage keeping the head steady in the opposite direction.

If these remedies fail, two or three incisions transversely through the skin, where it is contracted, may be made. If the cause is from several muscles being contracted, the cure will be more difficult; but if there is a contraction of the *mastoid* muscle only, or, as called by some, the *sterno-mastoid* muscle, the cure is effected by dividing it.

In this operation, *Mr. Sharpe* directs us "to make a transverse incision through the skin and fat, something broader than the muscle, and not above half an inch from the clavicle; then passing the probed razor with care underneath the muscle, draw it out, and cut the muscle. After the incision is made, the wound is

to be filled with dry lint, and always dressed so as to prevent the extremities of the muscles from re-uniting; to which end they are to be separated from each other as much as possible, by the assistance of a supporting bandage for the head during the whole time of the cure, which will generally be about a month."

Mr. Pott directs to cut through the muscle as near the middle as may be, taking care not to wound the carotid artery, nor the jugular vein. Dr. Hunter prefers making the incision near the sternum: he says, that at the lower part of the muscle it is best to perform this operation, because, there, the cellular membrane is not in any great proportion. Mr. Sheldon advises us not to use the razor above named, as we may endanger cutting the carotid artery, the jugular vein, and the eighth pair of nerves. He prefers the incision knife, to cut gently in a transverse direction; in that case the fibres will fly from the edge of the knife, and, with a moderate attention, the dangers just mentioned will be avoided. See Bell's Surgery, vol. iv. p. 366. White's Surgery, p. 387.

CERVUS, (from *κερως*, *cornu*; so called because of the exuberance of its horns). The STAG, HART, or MALE of the red deer. The flesh of these animals, until they are three years old, is excellent. The bone of the stag's heart, called *crux cervi*, from its shape being that of a cross, is only the tendons of the muscles of its heart hardened. This bone, as it is called, should be very white.

Balls are formed in their stomachs from the hairs which they swallow when licking themselves. These balls are called *elaiophila*. See CAPRA ALPINA.

The tears of a stag are the sordes collected in the inner angles of the eye, resembling wax. This matter hath many virtues ridiculously attributed to it, and is given in doses of three or four grains.

CERVUS DAMA. See DAMA.

CERVUS MINOR AMERICANUS BEZOARTICUS. The deer which produces the West Indian bezoar, q. v.

CERVUS ODORATUS. See MOSCHUS.

CERVUS RANGIFER. The REIN DEER, called by some authors *tarandus*, and *máchlis*. It is an animal very common in all the northern regions, of the shape of a stag, but its body is thicker, and its whole make much more robust and strong. It is of great use as a beast of carriage to the Laplanders, and almost all the northern nations. Scheffer alleges, from Tornæus, that though a cloven footed animal, and plainly of the deer kind, it does not chew the cud; but this is wholly disbelieved by the more accurate naturalists. Its horns and hoofs have been said to be of use in spasmodic affections.

CESTREUS. See MUGILIS.

CESTRITES VINUM, (from *κετρινος*, *betony*). Wine impregnated with betony.

CESTRUM, (from *κεστρον*, *a dart*; so called either from the shape of its flowers, which resemble a dart, or because it was used to extract the broken ends of darts from wounds). See BETONICA.

CETA'CEUS, (from *cete*, *a whale*). Cetaceous fishes are very large, bring forth a perfect animal instead of spawn: like viviparous animals, they respire by means of lungs, and nourish their young with milk.

CE'TE, (from the Chaldaean word *kota*). This term is usually applied to the spermaceti whale; *physter macrocephalus* Lin. See SPERMACETI.

CE'TERACH. See ASPLENUM.

CE'TUS. See CETE. The WHALE. There are many kinds of this fish; but the two principal are the Greenland whale: also called *balæna vulgaris*, *balæna major*, *musculus*; according to Pliny, *mysticetus*: the GREENLAND, or BLACK WHALE. The spermaceti whale is the *physter macrocephalus*.

It is from the upper jaw that whale bone is taken, and from no other part of this fish. Besides this bone, its only produce is its oil, used for burning in lamps, but of no use in medicine. In Paris, they have two sorts of whale oil: the best is called *huile de grande baye*: it is made from the blubber immediately after it is taken out of the fish, and is not so offensive in smell as that from Holland, which is melted down after their arrival.

The latter also called *cachalot*, *catodon*, from having teeth only in the lower jaw, *balæna macrocephala*, *trompa*, *byaris*, *occa*. The SPERMACETI WHALE does not afford any whale bone; but its teeth are ivory. From its body it yields a finer oil than that from the Greenland species; as well as SPERMACETI, q. v.

CEVADILLA, (from *cevada*, *barley*, Spanish). Called also *sebadilla*, *sabadilla*, *causticum Americanum*, *hordeum causticum*, *canis intersector*. INDIAN CAUSTIC BARLEY. *Veratrum sabadilla*, not included in the Species Plantarum. It is the seed vessel of a Mexican plant; like a barley ear, but with seeds not exceeding the size of lintseed. They are reckoned the strongest of the vegetable caustics. Monardes says, that for destroying vermin, and as a corrosive for some kinds of ulcers, they are equally effectual with the actual cautery. Dale thinks the capsula of the seed only is used: the taste is, however, bitter and acrid; in quality highly drastic, and powerfully anthelmintic. It is also diuretic and emetic. The dose to a child from two to four years old, is two grains; from hence to eight, five grains; from eight to twelve, ten grains.

CEVIL. See LUDUS HELMONTII.

CHA'A. See THEA.

CHACARILLA. See THURIS CORTEX.

CHEREFOLIUM, CHÆROPHYLLUM, (from *χαίρω*, *to rejoice*, and *φύλλον*, *folium*, *a leaf*, so called from the abundance of its leaves). Called also *cerefolium*, *gingidium*; COMMON CHERVIL. It is the *scandix cerefolium* Lin. Sp. Pl. 368. It is an umbelliferous plant, with winged leaves, like those of parsley, producing smooth long seeds, shaped like a bird's beak; a native of the southern parts of Europe, sown annually in our gardens, and slightly aromatic, aperient, and diuretic, differing not from parsley in its medical virtues. Distilled with water, it affords a small quantity of essential oil.

CHÆREFOLIUM SYLVESTRE PERENNÉ CICUTÆ FO'LIO, *Cicutaria vulgaris*, *myrrhis sylvestris*, *cerefolium sylvestre*; WILD CICELY; COW WEED. *Chærophyltum sylvestre* Lin. Sp. Pl. 369. The roots are poisonous, causing difficulty of breathing, torpor, and delirium. The roots resemble parsnips, and are called by the country people MADNIPS. The leaves resemble those of hemlock.

CHAIARXA'MBAR. See CASSIA FISTULARIS.

CHAI'TA. Properly the name of quadrupeds; but Rufus Ephesius expresses by it the hair of the hind head.

CHA'LAPA. See JALAPA.

CHALA'SIS, (from *χαλαω*, *to relax*). See RELAXATIO.

CHALA'STICA MEDICAME'NTA, (from the same). RELAXING MEDICINES.

CHALA'ZÆ, and CHALA'ZIA, (from χαλαζαι, hail stones; grandines lupæ). This name is given to a white knotty string at each end of an egg, formed of a plexus of the fibres of the membranes, by which the yolk and the white are connected: it is sometimes called *argutum*.

It is also a species of the hordeolum. STYE, STIAN, or STITHE, a moveable, hard, white, encysted tumour on the margin of the eye lid, resembling a hail stone; and differs from the *crithe*, another species, only in being moveable. It continues long, and proceeds slowly, and is often merely an enlargement of one of the sebaceous glands in consequence of obstruction; but occasionally of a more solid consistence. Sometimes it may be dispersed with the unguentum cœruleum fortius, and with a few roses of calomel. If they fail to relieve, make an incision through the skin which covers them, and dissect the tumour clearly out, or touch the skin over them with caustic, until the whole is wasted. See St. Yves on the Disorders of the Eye. Bell's Surgery, vol. iii. p. 264. Nos. Meth. Ocul. of Dr. Wallis, p. 4.

CHALBA'NE. See GALBANUM.

CHALCA'NTHUM, (from χαλκος, brass, and ανθος, a flower). FLOWERS OF BRASS. See VITRIOLUM.

CHALCEDONIUS, is the name of a medicine, which Galen directs to be used in disorders of the ears. Also a species of onyx stone brought from Chalcedon.

CHALCI'TIS, (from χαλκος, brass). The native is said to be a vitriolic mineral, containing copper and iron, of a copperish colour. As it cannot be procured, Dr. Alston thinks that its best succedaneum is the *chalcitis officinarum*. See VITRIOLI COLEOTIAR, and VITRIOLUM VIRIDE.

CHALCOI'DEUM, Os. The os cuneiforme of the tarsus. See CUNEIFORME OS.

CHALCOS. See Æs.

CHALCUTE. BURN'T BRASS. See Æs USTUM.

CHALICRA'TON. WINE and WATER, (from χαλκίς, an old word that imports pure wine, and κεραννυμι, to mix).

CHALI'NOS. BRIDLE. This word is sometimes used to express that part of the cheeks which, on each side, is contiguous to the angles of the mouth, as the part where the bridle of a horse is placed.

CHALYBEA'TÆ A'QUÆ. See AQUÆ MINERALES.

CHALY'BIS RUBI'GO and SAL. See FERRUM.

CHALYBS, (from *Chalybes*, a people of Pontus, who dug iron out of the earth). STEEL; called also *acies*. As a medicine, it differs not from iron. (V. FERRUM.) See Neumann's Chemical works, the Dictionary of Chemistry.

CHALYBS TARTARIZA'TUS. See FERRUM.

CHAMA, (from χαμα, to gape; so named from its wide mouthed shell). BASTARD COCKLE; called also *glycimeris magna*, and *chama glycimeris*. They are found in the Mediterranean sea, and are similar to our common cockle, and other shell fish.

CHAMÆ'ACTE, (from χαμαι, upon the ground, ακτή, the elder). See EBULUS.

CHAMÆBA'LANOS, (from χαμα, and βαλκάνος, a nut). See OROBUS.

CHAMÆ'BATOS, (from χαμαι, and βαίω, to go; so called from its creeping along the ground). See RUBUS VULGARIS.

CHAMÆCE'DRYS, (from χαμαι, and κεδρος, cedar). See ARBROTANUM FEMINEUM.

CHAMÆCE'RASUS, (from χαμαι, and κερσος, cherry tree). See CAPRIFOLIUM.

CHAMÆCI'SSUS, (from χαμαι, and κισσος, ivy). See HEDERA TERRESTRIS.

CHAMÆCI'STUS, (from χαμαι, and κυστος, cystus). *Panax chironium*, *consolida aurea*; *cistus helianthemum* Lin. Sp. Pl. 744. LITTLE or DWARF CISTUS, or SUN FLOWER. It is vulnerary, and is supposed to make a good gargle in diseases of the throat.

CHAMÆCLE'MA, (from χαμαι, and κλεμα, ivy). See HEDERA TERRESTRIS.

CHAMÆDA'PHNE, (from χαμαι, and δαφνη, the laurel). See LAUREOLA MAS.

CHAMÆ'DRYS, (from χαμαι, and δρυς, the oak). GERMANDER. *Chamædryes minor repens*; *vulgaris*. Also called *quercula calamandrina*, *trissago*; *chamædrops* P. Aginetæ and Oribasii. SMALL GERMANDER, and ENGLISH TREACLE. It is the *teucrium chamædryes* Lin. Sp. Pl. 790. CREEPING GERMANDER.

The chamædryes is a small, creeping, shrubby plant, with square stalks, small, stiff, oval leaves, notched from the middle to the extremity, like those of the oak tree, set in pairs at the joints, and purplish labiated flowers, set thick together, wanting the upper lip. It grows wild in France, Germany, and Switzerland. It is sometimes found wild in England, but is generally raised by culture in gardens. It flowers in June and July.

The leaves and tops are slightly bitter and aromatic; and esteemed mildly aperient and corroborant. They have been held in esteem in uterine and rheumatic complaints; in intermittent fevers; scrofulous affections, and other chronic complaints. At present, however, they are little used. The best time for gathering this herb is when the seeds are formed, and the tops are then preferable to the leaves. When dry, the dose is from ʒss. to ʒi. Either water or spirit will extract their virtue; but the watery infusion is more bitter. This plant is an ingredient in the noted powder, called from the duke of Portland, of which we add the original receipt.

Take of the roots of round birthwort and gentian, the tops and leaves of small germander, lesser centaury, and ground pine, of each equal parts: powder them all together. Of this powder a drachm must be taken, in any convenient liquor, every morning, fasting, for three months; then two scruples for three months; and, after that, half a drachm for six months: and, to conclude the process, half a drachm every other day for a year. Ætius calls a powder similar to this, *antidotes ex duobus centaureæ generibus*; Cœlius Aurelianus, *diacentaurion*.

Experience, in general, hath tended to lessen the credit of this composition, which hath little more than its antiquity to support the character with which it was lately raised. It differs but little from the diacentaurion of Cœlius Aurelianus, the pulvis principis Mirandolæ, climax vel scala sacra, and others, of which an account is given in the Lond. Med. Obs. and Inq. vol. vi. p. 126, where also the origin of the duke of Portland's powder is traced back to these boasted remedies. We

need not add on this subject to our former observations on bitters, and on the gout cordial. See AMARA, and ARTHRITIS.

CHAMÆ'DRYS IN'CANA MARI'TIMA. See MARUM SYRIACUM.

CHAMÆ'DRYS FRUTE'SCENS. See TEUCRIUM.

CHAMÆ'DRYS FRUTICO'SA SYLVE'STRIS MELI'SSÆFO'LIO. See SALVIA SYLVESTRIS.

CHAMÆ'DRYS PALUSTRIS AL'BIVM REDO'LENS. See SCORDIUM.

CHAMÆ'DRYS SPURIA ANGU'STIFOLIA, vel LATIFOLIA. See VERONICA.

CHAMÆ'DRYS. A name of a species of caryophyllata, called *avenens*.

CHAMÆLE'A, CHAMELE'A, (from χαμαι, on the ground, and ελαια, the olive-tree). WIDOW-WAIL. *Daphne Alpinia* Lin. Sp. Pl. 510. A shrub, with leaves like the olive-tree. The juice is a powerful hydragogue and cathartic, but much milder than mezereon, and many other plants which belong to the same genus. If it is applied to the pubes and abdomen of dropsical patients, no medicine is said to be more effectual in promoting urine. See LAUREOLA FEMINA.

CHAMÆLEA'GNUS, (from χαμαι, and ελαια, the wild olive). See MYRTUS BRABANTICA.

CHAMÆLEMA, (from χαμαι, and κλημα, ivy). See HEDERA TERRESTRIS.

CHAMÆLE'ON, (from χαμαι, humi, and λεων, lion; that is, dwarf lion). A lizard, supposed to be capable of changing its colour at pleasure. It is also the name given to some thistles from the variety and uncertainty of their colour, and to some metallic preparations from the same variety.

CHAMÆLE'ON ALBUS, &c. See CARDUUS PINEA and CARLINA.

CHAMÆLE'ON VE'RUM. See CNICUS.

CHAMÆLEUCE, (from χαμαι, and λευκη, the herb colt's foot. See TUSSILAGO.

CHAMÆLI'NUM, (from χαμαι, and λινον, flax). See LINUM CATHARTICUM.

CHAMÆLI'NUM VU'LGARE. See KNAWEI.

CHAMÆME'LUM, (from χαμαι, and μελον, an apple; because it grows on the ground, and has the smell of an apple). CAMOMILE. Galen calls it *euanthemum*. It is corruptly named *camomilla*. The following are the most common species.

CHAMÆME'LUM NO'BILE. Cham. Romanum *leucanthemum odoratius*, vel *odoratissimum repens*; by Dioscorides, *chrysocallia*; COMMON CAMOMILE. It is the *anthemis nobilis* Lin. Sp. Plant. 1260. Nat. order *compositæ radiatæ*.

It is found wild in moist pasture grounds in many parts of England, but is commonly cultivated in gardens. It flowers in July, August, and the following summer months; and the seeds come to perfection at the time of flowering. The leaves and flowers have a strong, though not ungrateful smell, and bitter taste. The flowers are more aromatic and bitter than the leaves and the stalks; the yellow disk is by far the strongest. The smell and taste are both improved by careful drying, and they lose very little by long keeping. These flowers are found to consist of a bitter extractive part, and an essential oil. The former is the tonic, and the latter the carminative portion.

The flowers only are used internally: they are bitter, carminative, anodyne, antispasmodic; of particular use in cold flatulent colics, especially if joined with aromatics; in nephritic, hysteric, hypochondriac, and other spasmodic disorders. The vomiting of breeding women, and the after-pains of parturition, are greatly relieved by them; and it has been idly supposed that they will prevent the accession of puerperal fever, and promote the uterine discharges. In agues, from half a drachm to 3 i. of the powder is given every two or three hours during the intermission; but as this quantity is apt to run off by the bowels, it is usually joined to an opiate or astringent. The camomile is useful in spasmodic colics, and also in the dysentery, from its laxative power; but in diarrhœa it has been found hurtful. In fevers of the low and irregular kind, attended with visceral obstructions, especially when too nearly allied to continual fevers to admit of the bark, the camomile is assisted by a mixture of fixed alkaline salts, and other corroborating medicines. A warm infusion, from two to three ounces, taken twice a day, has been efficacious in relieving pains of the stomach. In much larger quantity, it excites vomiting, and promotes the operation of emetics; for which purposes it is frequently given. In general, camomile flowers possess in a very great degree all the virtues of bitters (see AMARA), rendered more effectual by the warmth of the bitter oil, while, from the total absence of the astringent principle, they are of considerable service in pulmonary affections. They seem superior in most respects to the quassia, the columbo, to the angustura bark, and perhaps the myrrh; yielding perhaps only to the columbo, where bile abounds in the stomach. If it proves purgative, the best addition is the extract of the logwood. Externally, the flowers are used in the decoction for fomentation, and are also an ingredient in the decoction for clysters.

The dose may be from gr. x. to 3 i. of the dry powder; of the fresh juice from the whole herb, from one to six ounces, which, if taken just before the paroxysm of agues, is said to be effectual in a few doses. This juice is supposed to be peculiarly useful in strangury, asthmas, jaundice, and dropsies.

Camomile flowers yield their virtue to water and to spirit: the dry flowers make a more agreeable infusion than those that are fresh or newly dried; and the most grateful is when cold water only is used. Distilled with water, they impregnate it strongly; and, from the flowers, a small proportion of essential oil may be thus obtained. This oil is of a yellowish colour, and possesses all the virtues of the flowers in an eminent degree.

Externally, this herb is discutient and antiseptic; but the flowers possess the greatest degree of these qualities. Dr. Pringle says, that their antiseptic power is 120 times greater than that of sea salt.

A green oil is prepared from the herb, while it is fresh, in April and May at furthest, by boiling it with olive oil until the leaves are almost crisped: but as boiling dissipates the most efficacious part of the herb, the best method is to steep the flowers cold in the oil, and to strain it off as it is wanted.

*Extractum Chamæméli.* EXTRACT OF CAMOMILE, is prepared by boiling the flowers in distilled water,

pressing and straining the decoction. When the fæces have subsided, the decoction is evaporated in a water-bath saturated with sea salt, to a consistence proper for making pills. Lond. Pharm. 1788. This extract is remarkably antiseptic, according to the experiments of Sir John Pringle; and in doses of one or two scruples, either given by itself, or added to other remedies, proves highly beneficial in flatulence, indigestion, and pains of the stomach and bowels. In the same manner have the college of physicians of London ordered the extract of broom tops, gentian, black hellebore, liquorice, rue, and savine, to be made. But if the extract of this flower is obtained from a spirituous tincture, it retains much of its flavour, as well as its bitter taste. Lewis's and Cullen's Mat. Med.

CHAMÆME'LUM VULGA'RE, *leucanthemum* Dioscoridis; COMMON WILD CORN, or DOG'S CAMOMILE. It is the *matricaria chamomilla* Lin. Sp. Pl. 1256. It is upright, annual, and grows wild in corn fields. In France, and other countries on the continent, its flowers are used indiscriminately with the other species, but they are weaker and more disagreeable. The oil obtained from this species, by distillation, is of a fine blue colour, but the air soon changes it to a yellow.

CHAMÆME'LUM FLO'RE PLE'NO, called also *chamæmulum nobile flore multiplici*, and DOUBLE CAMOMILE. *Anthemis nobilis* var.  $\beta$ . They are produced by culture, and differ in their flowers from the Roman camomile above described in being double, or having several rows of the white petals, and the thick disk proportionably smaller. Sometimes the disk is filled with the petals.

The single and the double flowered sorts are often used indiscriminately: their leaves differ very little; but as the active parts chiefly reside in the disk or tubular part of the florets, which in the single flowers are largest, the latter are generally preferred.

The single sort affords most oil.

CHAMÆME'LUM FETIDUM, called also *cynanthemis*, *cotula fetida*, *anthemis cotula* Lin. Sp. Pl. 1261. STINKING CAMOMILE, MAITHS, and MAY-WEED. It is annual, growing in waste grounds and amongst corn. It is more upright than the other species; its leaves are finer, and flowers closer.

In its qualities it differs greatly from the three preceding. Its smell is disagreeable; its flowers are almost insipid, but the leaves have a strong, acrid, harsh taste. It has been esteemed strongly sudorific. Dr. Brown Langrish gives an account of a decoction of this plant, recommended by a gypsey, throwing a person affected with a rheumatism into a profuse sweat, and curing him of the disease.

CHAMÆME'LUM CANARIE'NSE. The *leucanthemum Canariense*. *Chrysanthemum frutescens* Lin. Sp. Pl. 1251.

CHAMÆME'LUM CHRYSA'NTHENUM. See BUPHTHALMUM GERMANICUM.

CHAMÆME'SPILUS, (from *χαμαι*, on the ground, and *μεσπιδος*, a medlar). See ARIA.

CHAMÆMO'RUS, (from *χαμαι*, and *μορος*, moros, a mulberry tree). Called also *chamæ-rubus foliis ribis Anglicæ*, *rubus palustris humilis*, *vaccinium Lancastrense*, *rubus Alpinus humilis Anglicus*. *Rubus chamæmorus* Lin. Sp. Pl. 708. CLOUD-BERRY, and KNOT-BERRY.

It is a shrub which grows on boggy mountains in England, and more northern regions; the leaves re-

semble those of the mallow or of the currant tree; the fruit is like the raspberry; when ripe it is sweet, tart, and of a yellowish red. It ripens in July and August. When ripe and boiled, without any addition, to the consistence of a pulp, it will not soon spoil, if closely covered in pots; and, as an antiscorbutic, far excels the scurvy grass, and vegetables of that tribe in common use.

The *chamæmorus Norwegiæ* is a variety of the same species. Raii Hist.

CHAMÆPEU'CE, (from *χαμαι*, and *πευκη*, the pine tree). See CAMPHORATA.

CHAMÆPITU'NUM VI'NUM. It is wine in which the bruised green leaves of the *chamæpitys* have been infused.

CHAMÆPITYS, CHAMÆPITY'S MAS, (from *χαμαι*, and *πιος*, the pine tree.) *Arthetica* vel *arthritica*, *ajuga*, *abiga*; *iva arthritica*. Dioscorides says, that it was called *holocyron* in Pontus, *Ionia* in Athens, and *sideritis* in Eubœa. COMMON GROUND-PINE. It is the *teucrium chamæpitys* Lin. Sp. Pl. 787.

It is a low hairy creeping plant, with square stalks, whitish clammy leaves, cut deeply into three narrow segments, set in pairs at the joints, and yellow labiated flowers without pedicles, and wanting the upper lip. It is annual, grows wild in sandy and chalky grounds in some parts of England; flowers in July and August, and has a long slender fibrous root.

The leaves are moderately bitter, of a resinous but not disagreeable smell, approaching in this respect, as in their external form, to those of the pine tree. They are aperient, stimulant, and corroborant; are commended in palsies, rheumatisms, gout, and uterine obstructions; are attenuating and diuretic, and in general of similar virtues with the *chamædry*s, but more active from an admixture of an essential oil similar to turpentine.

They yield their virtue to water, but somewhat more fully to spirit: on distillation with water, a very small portion of essential oil is obtained, resembling that from turpentine. An infusion of the dried herb in white wine is the best preparation, but the dried leaves may be taken to a drachm for a dose. They are an ingredient in the *pulvis ad rheumatismum*. See CHAMÆDRYS.

CHAMÆPITYS MOSCHA'TA, also called *iva moschata* *Moscheliensium*; *chamæphytis anthyllis*. *Teucrium iva* Lin. Sp. Pl. 787. FRENCH GROUND-PINE.

It is weaker, but of similar virtues. See CHAMÆPITYS.

CHAMÆPLION. A name in Oribasius for the ERYSIMUM, which see.

CHAMÆRAPHANUM, (from *χαμαι*, on the ground, and *ραφανος*, the radish), the upper part of the root apium (P. *Ægineta*). It is also the dwarf radish.

CHAMÆRI'PHES. See PALMA MINOR.

CHAMÆRODODE'NDRON, (from *χαμαι*, on the ground, and *ροδοδενδρον*, the rose laurel). See ÆGOLETHRON.

CHAMERU'BUS, (from *χαμαι*, and *rubus*, the bramble). See CHAMEMORUS.

CHAMESPA'RTIUM, (from *χαμαι*, and *σπартιον*, Spanish broom). GENISTE'LLA. See GENISTA TINC-TORIA.

CHAMÆSYCE, (from *χαμαι*, and *συκη*, a fig tree).  
See PEPLION.

CHA'MBROCH. See TRIFOLIUM.

CHA'MOIS. See CAPRA ALPINA.

CHAMOMILLA. See CHAMÆMELUM.

CHAMPACAM. (Indian.) A large tall tree in the East Indies, which bears fragrant flowers twice a year, and not fruit until it is advanced in age. Ray thinks it is the champaca of Bontius. *Michelia champaca* Lin. Sp. Pl. 756. The dried root of its bark is an emmenagogue: the flowers are reckoned cordial.

CHA'NCRE, a CANKER, (French); called also *caroli*. The ancients called such ulcers on these parts *caries pudendorum*.

The small irritable pustules which have obtained this appellation do not appear at any certain period after the application of the virus; sometimes they form in less than twenty-four hours; at others not before six weeks; but most frequently from four to ten days, and are at first seldom larger than a millet seed. They occasionally make their appearance over all the parts of generation, and, in some instances, even on the contiguous parts, as on the scrotum, all over the penis, and on the lowest region of the abdomen. They may indeed form on all the soft parts of the body; but they are most frequently seated on the glans penis, and on the prepuce, near to its connection with the glands; often about the frænum, and in some instances on the very point of the glans, and even within the verge of the urethra; here, as well as near the frænum, they prove always very troublesome, and more difficult to cure than in other parts of the penis. The colour, quantity, and consistence of the matter, are exceedingly variable. It is usually of a dirty yellow green colour, often tinged with red. Sores of this kind are sometimes of a simple innocent nature, and they usually heal in the course of a short time, merely by being kept clean; whilst they will gradually become worse, if they are venereal, should mercury not be employed, or if they are not treated with escharotic or astrigent applications. A real venereal chancre is seldom so large at the first as the base of a split pea, and the edges of the sore are elevated, somewhat hard and painful: still, in some few instances, we observe a slight superficial ulceration, not attended with either pain or hardness, and which, by the consequences alone, we find to be venereal. In general, however, such sores are not venereal, and the want of hardness and of painful irritability are the chief distinctions.

There are other chancres, which become suddenly elevated into extensive vesications, containing a clear lymph, but more frequently tinged with blood; from this livid appearance, these chancres are judged of a more dangerous nature than others; but the colour depends entirely on the blood being mixed with the serum; and on their contents being discharged, the parts beneath appear clean, the surface is only excoriated, without being affected in any other manner. In women, chancres exactly resemble those in men, and occur chiefly on the internal parts of the labia pudendi, nymphæ, clitoris, and the entrance of the vagina and urethra; but seldom or never within either of these passages.

If a chancre is seated in the urethra, it may be mistaken for a gonorrhœa, but may be distinguished by the smallness of the discharge, the pain during erection

being in the extremity of the penis, or a particular spot in the urethra, but principally by examining with the touch of a probe or bougie whether it is callous or not. In almost every instance, however, a chancre never occurs in the urethra, except it be within the reach of the sight, often of the touch.

When a venereal chancre, distinguished by its appearance, its hardness, and its painful irritability, occurs, it is seemingly the first object to crush the disease in its bud. It has been indeed doubted whether in that state absorption takes place; but we need not discuss the question, since no prudent practitioner would agree to omit internal remedies; and in the inquiry into the previous symptoms, the appearance of a chancre leads most decisively to the use of internal mercurials.

If, indeed, after exposure to infection, an ulceration appear, it is most probably only a local affection; and a cure might be effected by a very superficial dressing; yet as we have no means of being certainly safe, the cure of even the slightest chancre should never be trusted to external remedies. In every case of ulcerated chancre not attended with much inflammation, after wiping the sores as clean as possible, let them be sprinkled well with the hydrargyrus nitratus ruber, finely powdered, and pledgets of any common ointment applied over it; and after two or three dressings, the ulcer will be generally clean, and nearly healed. Finely powdered calomel will be equally effectual, and the application is said to give a pleasing glowing warmth.

The free use of the lunar caustic is recommended highly in the cure of this complaint, and particularly in its incipient state: it effectually cures, by destroying the diseased parts, which soon become clean, and heal as quickly as sores proceeding from any other cause, and of the same magnitude. In general they are seldom troublesome but from the pain, and the great doubt is whether they should be suffered to remain as an index of the effects of mercury internally, or destroyed as local disease by a caustic. We have no doubt of advising the latter, since in a part where the circulation is languid, they may not be readily affected by internal mercurials, and we have equally certain guides of the necessary extent of a mercurial course. See Astruc on the Venereal Disease, or Chapman's Abridgment of Astruc, Heister's Surgery, Lond. Med. Trans. p. 337; and particularly Hunter and Bell on the Venereal Disease.

CHAO'VA. The Egyptian name for COFFEE. See COFFEA.

CHA'RABE, (from *charaba*, Arab). See SUCCINUM.

CHARA'CIAS, (from *χαράξ*, a bulwark, or fence). An epithet given to some plants which require support, as the vine, &c.

CHARA'CTER, (from *χαρῶσα*, to engrave.) In botany and nosology it is that assemblage of marks by which the species of plants or diseases are distinguished from each other. Character signifies also an hereditary disposition to some particular disease.

In chemistry it is a mark importing a particular substance; or it is a sign invented to represent the principal substances and operations in a concise manner.

CHARA'NTIA. See MOMORDICA.

CHA'RDONE. See CINARA SPINOSA.

CHARISTOLO'CHIA, (from *χαρις*, joy, and *λοχια*, the flux of women after child-birth.) So called from its usefulness to women in child-birth. See ARTEMISIA.

CHA'RME, CHA'RMIS, the name of a cordial antidote mentioned by Galen.

CHARO'NIUS, (from *Charon*, the boatman of the Styx, surrounded by noxious vapours.) CHARONIAN. An epithet for caves, some of which are in Italy, where the air is loaded with deleterious vapours.

CHA'RTA VIRGI'NEA. So called from its likeness to a piece of fine paper. See AMNION.

CH'ARTREUX, Po'UDRE DE, invented by some friar of the Carthusian order. See ANTIMONIUM.

CHA'SME, *χασμη*, (from *χαίνω*, to gape.) See OSITATIO. Hence, in English, a chasm.

CHA'TE. See CUCUMIS ÆGYPTIA.

CHAULIODO'NTA, (from *χάωλω*, to throw out, and *ὄδον*, a tooth.) So the Greeks call those animals whose teeth grow to a great length out of their mouths, as the boar and the elephant.

CHE'DROPA, (quasi *χειρ*, manus, *δρεπω*, colligo.) A general term for all sorts of corn and pulse, because they are collected by the hand.

CHEILOCA'CE, (from *χειλος*, a lip, and *κακον*, an evil.) THE LIP-EVIL. A swelling of the lips. See CANCRUM ORIS, and LABRI-SULCIUM.

CHEIME'TLON, (from *χειμα*, winter.) See PERVIO.

CHEI'MIA, (from the same.) COLD, SHIVERING.

CHEIRA'PSIA, (from *χειρ*, the hand, and *απτομαι*, to touch.) SCRATCHING.

CHE'IRI. So named from the likeness of its blossoms to the fingers of the hand; called also *leucolum luteum*, *viola lutea*, COMMON YELLOW WALL-FLOWER. *Cheiranthus cheiri* Lin. Sp. Pl. 924.

The stalks are woody and brittle; the leaves oblong, narrow, sharp pointed, smooth, and of a dark green colour; the flowers numerous, yellow, tetrapetalous, open successively on the tops, are followed by a long slender pod, containing reddish flat seeds. It grows wild on old walls and among rubbish, and flowers in April and May.

The flowers have an agreeable smell, but to the taste are nauseously bitter and pungent. Water takes up all their active matter; but no essential oil is obtained by distillation, though in this way a water is obtained that possesses much of the flavour of these flowers. They are reckoned among the nervines, deobstruents, diuretics, and antiparalytics.

CHEIRIA'TER, (from *χειρ*, a hand, and *ιατρος*, a physician.) A SURGEON; called also *chirurgus*. Hence *cheiriaticus*, a term appropriated to chirurgical remedies and operations. V. CHIRURGIA.

CHEIRI'SMA, (from *χειρίζομαι*, to labour with the hand.) HANDLING, or a manual operation.

CHEIRI'XIS. SURGERY.

CHEIRONO'MIA, (from *χειρονομω*, to exercise with the hands.) CHIRONOMIA. An exercise mentioned by Hippocrates, which consists of peculiar gesticulations of the hands.

CHEIRUR'GUS, (from *χειρ*, manus, and *εργον*, opus.) See CHEIRIATER.

CHE'LA, (from *χεῖλ*, to take.) A FORKED PROBE mentioned by Hippocrates for extracting a polypus from the nose. In Rufus Ephesius it is the extremities of

the cilia; but most commonly it is used for claws, particularly of crabs. It also signifies fissures in the heels, feet, or pudenda.

CHEL. CANC. PULV. C. See CANCER FLUVIATILIS.

CHELI'DON, (from *παρα το χειλεσιν αδειν*, because it chatters with its lips or bill.) THE SWALLOW. Also the hollow at the bend of the arm, from its shape.

CHELIDO'NIA, (from *χειληδον*, the swallow, because swallows are said to open the eyes of their young by it; or because it blossoms about the time in which these birds appear.) The GREATER and LESSER CELANDINES. See CHELIDONIUM MAJUS.

CHELIDO'NIUM. See BRIONIA ALBA.

CHELIDO'NIUM MA'JUS, *fistulifer corniculatum luteum*, TETTER-WORT, and GREAT CELANDINE. *Chelidonium majus* Lin. Sp. Pl. 723.

This plant hath longish leaves, divided to the rib into roundish and indented portions, of which those at the extremities are the largest, of a bright green colour on the upper side, of a bluish green underneath, full of a gold coloured juice, as are likewise the stalks; from the bosoms of the leaves issue long pedicles, bearing clusters of tetrapetalous yellow flowers, which are followed by brownish pods, containing flattish shining black seeds; the root is thick at the top, with a number of fibres at the bottom, externally brownish, internally of a deep yellowish red or a saffron colour: it is perennial, grows wild in hedges and shady places; flowers in May and June.

The leaves and roots have a faint unpleasing smell, and to the taste are bitter and acrid; they give out their active matter to spirit and to water: the pungency they possess is not of the volatile kind, for hardly any of it rises in distillation; yet it is lessened by drying the plant, and inspissating infusions of it. Drying wholly dissipates its smell.

It is aperient, diuretic, and useful in the jaundice, when not accompanied with inflammatory symptoms. The fresh juice is used to destroy warts and films in the eyes; but for this latter purpose it is diluted with milk. Of the dried root from ʒ ss. to ʒ i. is a dose; of the fresh root infused in wine or in water the dose may be about ʒ ss.

The decoction of the fresh root is used in dropsy, cachexy, and cutaneous complaints.

CHELIDO'NIUM MI'NUS, called also *scrophularia minor*, *ficaria minor*, *chelidonia rotundifolia minor*, *cursuma*, *hemorrhoidalis herba*, *ranunculus vernus*, PILEWORT, and LESSER CELANDINE. *Ranunculus ficaria* Lin. Sp. Pl. 774.

It is a small plant, with roundish smooth shining green leaves, set on long pedicles; and slender procumbent stalks, bearing bright gold coloured solitary flowers of eight or nine petals which stand in three leaved cups, and are followed by clusters of naked seeds; the root consists of slender fibres, with a number of tubercles or little knobs. It is perennial, grows wild in hedges and moist meadows, and flowers in April.

The leaves are antiscorbutic, but are without smell, and have very little taste, though on chewing a slight pungency is perceived. The roots are reckoned a specific, if beat into cataplasms and applied to the piles; they yield a large portion of mucilaginous matter to water, are supposed to be diuretic, and to clear the skin

of tettery eruptions. Raii Synop. et Hist. *Oithonna* has been supposed to be the juice of *celandine*.

**CHELO'NE.** A TORTOISE. It also imports a part of a surgical machine mentioned by Oribasius. An instrument to make a gradual extension of any fractured limb, in which motion it resembles the slowness of *χελωνη*, a tortoise. A plant also whose crest resembles a tortoise shell.

**CHELO'NION.** A HUMP BACK; so called from its resemblance to the shell of *χελωνη*, a tortoise.

**CHELTENHAM WATER.** This arises from a spring near Cheltenham in Gloucestershire; and is one of the most celebrated purging waters in England. When taken from the fountain, it is clear and colourless, but somewhat brisk; has a saline, bitterish, chalybeate taste; it strikes a vivid purple colour immediately on being mixed with an infusion of galls. Its heats in summer from 53° to 59°, when the medium heat of the atmosphere was nearly 15° higher. When exposed to the air in an open glass vessel, it throws up a quantity of air bubbles, becomes turbid, and loses its brisk chalybeate taste and property of tinging an infusion of galls. On evaporation it is found to contain a calcareous earth, mixed with ochre, and a purging salt. In one gallon were found by Dr. Short 74 grains of calcareous earth mixed with ochre, and 673 grains of a purging salt. In the second experiment, 42 and 580; in the third, 70 and 622 respectively. Dr. Rutty found 36 grains of earth, 494 of salt, which was composed of vitriolated magnesia, and a small quantity of sea salt. Dr. Lucas, 4 grains of iron, 181½ grains of calcareous earth, mixed with a small portion of selenites, 362½ of salt of the nature of Epsom, but drier and finer. Dr. A. Fothergill found 480 grains of Glauber and Epsom salts, 5 grains of sea salt, 25 of magnesia, and 40 of selenite; together 550 of solid contents. The upper, or King's well, was discovered by the accidental sinking of a well after the king's residence there, by his command. The temperature of this water at eight in the morning, the beginning of August, was 54°. Its specific gravity was, at that temperature, 1059; and it boiled at 214½, when the barometer was at 29.60. Its sensible qualities were not very different from the other springs. It certainly contains a larger proportion of salts than the water usually employed; and the analysis of Dr. Jameson discovered the following contents: viz. sulphat of soda, 490 grains; sulphat of magnesia, 310; muriat of soda, 40; sulphat of lime, 38; carbonat of lime and magnesia, 34: in all 912 grains of salts, estimated in their crystallized state in a wine gallon of the water. This well seems to contain neither sulphur nor steel.

The principal diseases, for which the Cheltenham water is employed, are bilious; and to the Cheltenham wells resort those who from indolence, luxurious indulgences, a long residence in tropical climates, or other causes, labour under cachexy from a diseased, generally a scirrhus, liver. It is this state of the biliary system which is chiefly adapted for these waters; and they very successfully assist a mercurial course. In overflows of bile also, particularly where this fluid regurgitates into the stomach, occasioning headach and sickness, it assists in discharging it regularly. In the first instance, the steel seemingly counteracts its debili-

tating power; and in the latter, the carbonic acid gas prevents it from producing vomiting.

In gout the Cheltenham water is also occasionally recommended; and the cooling tendency of the salts is supposed to be counteracted by the stimulus of the steel: yet, perhaps, it is chiefly adapted to those cases of gout connected with complaints of the liver; in reality, to the broken constitution, which is the cause of both. In all stomach complaints, in hypochondriasis, and chlorosis, it is said to be useful; and, probably, may be so, though there are apparently other medicines better adapted to them. In jaundice, in scorbutic eruptions of different kinds, in scrofula, and the diseases connected with it, this water is useful. In inflammatory asthma, in amenorrhœa and leucorrhœa, in hæmorrhoids, and nephritic complaints, in short, wherever constant cooling laxatives are necessary, this mineral water has been employed; but in many of these diseases it is not superior to sea water, and in some perhaps inferior.

As a purge, this water is drank from one to three pints; though in general from half a pint to a quart is sufficient. It operates with great ease.

**CHE'LYS**, (from *χελυς*, a shell). See **PECTUS**.

**CHELY'SCION**, (from *χελυς*, the breast). A SHORT DRY COUGH.

**CHE'MA.** Blancard says it is a certain measure mentioned by the Greek physicians, supposed to contain two small spoonfuls; the Athenians had one of two drachms, and another of three.

**CHE'MIA**, vel **CHI'MIA**, (from the Arabic term *chamiah*, from *chamah*, to burn). **CHEMISTRY.** Among the Greeks it was called *χημια*, *χημεια*, and *χυμεια*; the last of which hath been generally followed by the later writers on this subject, though the most approved editors and other learned men have preferred the former. The modern Greeks write *χημεια*. It is also called *archimágia* and *pyrotéchnia*.

Though this branch of the science of nature is well known, the definition of chemistry has occasioned many discussions and tedious controversies. The first great object is to distinguish it from natural philosophy, a task which few authors have successfully performed; and we are on this account tempted to select the discriminating description of the Abbé Haüy, in the ablest system of natural philosophy yet published.

"When we consider," observes this author, "the general and permanent properties of bodies, or when the changes that these bodies undergo are slight, and they return to their former state, after the cause has ceased to act; when, also, the laws which determine the reciprocal actions of the same bodies are propagated to distances more or less considerable; the results of our observations are still within the confines of natural philosophy. But when the phenomena depend on the ultimate action which the molecules exert on each other, at distances almost infinitely small, by virtue of which the molecules separate to unite again in a different order, forming new combinations, with new properties, the study of the phenomena belongs to chemistry."

We seldom indulge ourselves with quoting the words of an author but for some particular object. This distinction, truly judicious and scientific, we consider as one of those positions on which we can securely rest, and to which we may have occasion to refer. At pre-

sent it serves only to introduce, and as a foundation for, a more precise definition of chemistry than any former author has offered. We shall consider chemistry, therefore, as comprehending the science of the mutual actions of the smaller particles of matter, either in decomposing natural bodies or producing new compounds. In this view, fire, electricity, and Galvanism, are its instruments only, and become the objects of chemistry when they enter into the composition of bodies; and in this view, also, the human body is a philosophical and chemical machine, though chiefly chemical. It sometimes partakes of both, in as much as its operations are carried on between particles at an indefinitely minute distance, but not always occasioning decomposition or new compounds with different properties.

Were we to treat of the history of chemical arts, we should be carried back to a very remote era: were we to speak of chemistry as a science, our history would scarcely yet have a beginning. Chemical arts do not imply chemical science; and we shall consequently overlook the fancies of those, who see in common operations the rudiments of what has since been so advantageously developed; who admire, for instance, the ingenuity of those ancient artists who could be so far instructed as to produce a scarlet dye, when they were in reality ignorant of such a colour.

The Egyptians, who have had the honour of inventing every science, probably without the accurate knowledge of any one, have appeared to claim chemistry as peculiarly their own. Plutarch tells us, that Egypt is called *Χημεία*, from its earth, like the black of the eye; but the name is more probably derived from *Ham*, as it is called by the psalmist *Al-chami*. The error arising from this name was fostered by the new Platonists, who forged works under the names of Hermes, &c. as those of the ancient Egyptians. Yet to these new Platonists we are perhaps indebted for many valuable facts. They were the first visionaries who aimed at changing the meaner metals to gold, a pursuit with which the discovery of an universal medicine was very early connected; and from them it was conveyed to the Arabians, by whom it was taught to Europeans. Themistius, the peripatetic, in the fourth century, and Aeneas of Gaza, in the fifth, speak of these attempts; the former in his 'Oratio ad Valentinum,' the latter in his Dialogue entitled 'Theophrastus.' With them and with the Arabians the art remained; nor did it reach Europe till after the capture of Constantinople, for the name was unknown to the Grecians of Europe till the time of Julius Firmicus, who lived under Constantine the Great.

The Arabians applied this new science to medicine, though not to any considerable extent. Their practice was mild and timid; and had any more active medicine been discovered, it is not probable, from their general conduct, that they would have been its patrons. The works of Geber, Rhazes, Avicenna, and Mesue, have reached us; and from them, were not our limits confined, we might trace very accurately the state of medicinal chemistry at that time. It is enough to remark, that it added little to the powers of medicine, though somewhat to the convenience of the practitioner. We speak not now of the new medicines which they introduced.

In Europe, the art of making gold filled the minds of

the chemists, or rather alchymists, to which they joined an almost equal anxiety to discover the universal medicine. This was sometimes supposed to be the same, sometimes a similar preparation; and as the former art depended, in their opinion, on the employment of mercury and antimony, many preparations of these metals must have occurred, and we can trace some of them at this time to these whimsical unintelligible works. Even among the alchymists, however, we perceive traces of sounder minds and more solid judgments mixed with their reveries; and the names of Albert von Bollstaedt, Roger Bacon, Raymond Lully, Albertus Magnus, Arnold of Villenuova, the Isaacs of Holland, and Basil Valentine (though probably not his true name), merit peculiar distinction. They mixed indeed the fancies, the superstitions, and the unintelligible language of the alchymists with their descriptions; but they discovered and detailed, often with precision, many valuable and important facts. The writings of Lully and Arnold, however, seldom merit the commendations which we have bestowed; and perhaps the praise of any portion of perspicuity might have been more limited. They were all of the thirteenth or fourteenth centuries.

The folly, the madness, and the wickedness of the alchymists, for their conduct at different times merited each title, continued without any considerable change. They worked in secret; and collected facts which were to supply at a future period the more rational chemists, but had little influence on the practice of medicine till the period of Paracelsus. This visionary of the sixteenth century burnt in solemn state the writings of Galen and his followers, professing to cure all diseases by chemical medicines alone. He was equally depraved in his moral, as he was insolent and ignorant in his medical, character. His precepts were generally dictated in fits of intoxication; and he owned to one of his favoured disciples, that he could not maintain his credit in any place above a year. He died in his forty-seventh year, boasting of having the power of prolonging his life to an indefinite period. From the mysticism of his language, many parts of which Dr. Motherby and his associate had preserved, and some specimens we have, perhaps with too great facility, retained, it will appear that little can be learnt from his works, which however, have been collected by his disciples in two volumes folio. He was succeeded in this path by Van Helmont, equally visionary as an alchymist, and more so in adopting the fancy of sympathetic medicine; but a man of talents, of observation, and, out of these departments, not without judgment. To Van Helmont, though nearly at the distance of a century from Paracelsus, and to Crollius, we owe the labours of Paracelsus in a more intelligible form; and we are certainly indebted to him for the invention or preservation of some very valuable chemical preparations. The original of Crollius appeared at Frankfort, in 1609, and was translated into English in 1670. Glauber, Kunkel, Kircher, and Conringius, were diligent and experienced chemists, who added greatly to the stock of facts, and to whom we are still indebted.

Chemistry, however, continued to be only a collection of detached facts, without any bond of connection, without any principle of union; nor, until the period of Becher and Stahl, did it assume the semblance of a

science. Becher died, like Paracelsus, at the age of forty-seven; but he had collected the various operations of chemistry, and united them by general principles: one of these was the supposition of phlogiston, which has only of late been, with reluctance, abandoned. Stahl, a man of singular talents, of an imagination lively and eccentric, but who wrote with a logical precision almost unexampled, assumed gratuitously the existence of this principle; and connected also, chiefly by its means, the numerous isolated facts of which chemistry then consisted. His cotemporary, Hoffman, applied this science, with more studied care, to medicine, and collected, with great anxiety, the labours of the more intelligent chemists who preceded or were cotemporaries with him. As a medical chemist, Hoffman merits the highest commendation: he was patient, industrious, and honest. He was, however, too eager, certainly too credulous. About the same period, with superior talents and similar faults, our own Boyle laboured in this vineyard; but, while we blame their credulity, we must make allowance for the splendour of numerous and surprising phenomena, which dazzled the imagination, and led the judgment captive. It was a new world, and what they believed was scarcely more extraordinary than what they saw.

To pursue the subject of medical chemistry, our chief object, we shall next mention the celebrated Boerhaave, who detailed, very advantageously, what former chemists had discovered, and added the result of many years unremitted industry. He unveiled the mysteries of the art, by employing the language of learning and philosophy unmingled with metaphor and an assumed obscurity. Probably, no author promoted, more successfully, the progress of chemistry, or applied it more advantageously to medicine; and he advanced it by these means rather than by splendid discoveries. After him followed Dr. Cullen, who, probably, brought to this science those extensive systematic views which distinguished him in every other. But the cold reserve of his descendants, their apparent indifference to his fame, repress all communication. We know only that his lectures were received with great approbation, and that his chemical knowledge was directed to medicinal improvements. To him we are indebted for the more general use, at least, if not the introduction, of some of the more active metallic preparations. Dr. Black followed his steps; and, though he pursued chemistry rather as an independent science, he seldom lost sight of its application to medicine.

In following the systematic authors, we have hastened too rapidly in our way. From the time of Boerhaave to the downfall of Becher and Stahl's boasted principle, numerous were the authors who improved this science. Among the Germans, *Neumann*, Pott, Cramer, *Cartheuser*, Margraaf, *Spielman*, De Born, *Plenck*, *Scheele*, and Gren; in Holland, *Ingenhouz* and *Van Mons*; in France, the *Geoffroys*, *Reaumur*, Du Hamel, *Hellot*; the two *Rouelles*, *Hombert*, *Macquer*, *Baumé*, *Sage*, *D'Arcet*, and *De Morveau*; in Italy, *Scopoli*, *Fontana*, *Liandriani*, *Cavallo*, *Volta*, and *Spallanzani*; in England, *Hales*, *Mayow*, *Lewis*, *Priestley*, *Black*, *Higgins*, and *Nicholson*; in Sweden, *Brandt*, *Wallerius*, *Cronstedt*, *Rinman*, *Scheffer*, *Gahn*, and *Bergman*. Those who have applied more particularly chemistry to medicine are marked by italics.

The early dawn of chemical improvements may be traced, in England, to the period of *Mayow*, *Hales*, *Kirwan*, and *Black*, of the old school; from *Priestley* and *Cavendish* of the new. *Gahn* and *Bergman*, *Sage* and *De Morveau*, *Scopoli* and *Spallanzani*, are on the confines of each system, and may belong to both. The experiments of *Hales* and *Mayow* had been forgotten, when *Black* elicited the first spark, which was to dazzle with the flame it excited. This embryo, if not neglected, scarcely treated with a parent's fondness, was cherished by *Cavendish* and *Priestley*; and the result was the splendid discovery of the composition of water; the existence and properties of many, permanently elastic, gases. *Lavoisier*, *De la Place*, *Berthollet*, and *Fourcroy*, followed; and from this period the distinguished chemists of every country have resigned the visionary phlogiston, and joined in adopting the pneumatic system. *Priestley* died an infidel; Gren but half converted. *Kirwan* and *Black* joined with apparent reluctance, after patient inquiry and full conviction, what is styled the antiphlogistic system. The revolution is now, we believe, complete: it is not heresy, but reformation.

The French chemists, not content with this splendid improvement, of which, indeed, they could not claim the honour, though they have made numerous additions, scarcely less valuable, perhaps, than the first discoveries of *Black* and *Cavendish*, have changed, in consequence of the establishment of the pneumatic system, the whole language of chemistry. They have thus attempted to make it exclusively their own. This vanity, so common in their nation, might excite a smile as harmless; and from the merits, *on the whole*, of the new nomenclature, command approbation, were it not from some serious inconveniences that will be found to result. At this time, the language of both sects is common, and little inconvenience is experienced; but, except to the experienced chemist, the labours of *Pott*, of *Neumann*, of *Margraaf*, *Macquer*, *Baumé*, &c. will be soon lost. Their language will no longer convey ideas; and experiments, most truly important and valuable, will be almost on a footing with Egyptian hieroglyphics. There is one remedy for this evil, which is the unmerciful pillage of French authors from their predecessors; and, as usual, the stolen goods are marked with the characteristics of their present owners, to conceal the depredations. This, however, is not sufficient: *juvat integros accedere fontes*; and, unfortunately, the streams are polluted. Various are the changes we have witnessed to adapt former facts to the theory of the moment. We would strenuously advise the student, therefore, to study the language of both sects; and the lately published lectures of *Dr. Black* are admirably adapted for this purpose. *Mr. Nicholson's Elements* also, published when the new theory was not fairly established, contains the explanation of the phenomena according to each system, and will answer the same purpose, though the new theory has received considerable improvement since the period of their publication.

Chemistry, so far as it relates to medicine, has been hitherto employed in the composition of medicines. In this branch, however, previous to the introduction of pneumatic chemistry, much was empirical and heterogeneous; ingredients, destructive of each other's powers,

were ignorantly or inconsiderately accumulated. It was the object to heap a great variety of medicines in one formula, that should one fail, another might succeed: forgetting that, though the imagination was boundless, the stomach was limited; and that, when the number of ingredients was increased, the dose of each was inconsiderable. In chemical formulæ, the error was greater from the union of heterogeneous substances; and, where the ingredient was retained, its utility was not understood. A striking instance of this kind was the chalybeate oxide in the preparation of the corrosive sublimate, which furnished the pure air that distinguishes this preparation. In the former case we have refined, perhaps, too far, as we shall show in the article of COMBINATION OF MEDICINES. In the latter, we have not been equally rash, yet we suspect we have often erred. In the articles, ARGENTUM VIVUM, and ANTIMONIUM, we have shown that the more simple modern preparations are different, in some respects, from those of the ancients. Chemistry, however, which first led the pharmacist from the path, will contribute to his recovering it.

In another branch, chemistry was seemingly misemployed; we mean in investigating the powers of medicines. The older chemists employed fire, almost exclusively; and vegetable remedies, the most opposite in their nature, yielded nearly the same products. Even bread, we are informed by Mr. Boyle, will produce, by distillation, the most acrid deleterious oil. In fact, in these destructive processes, new combinations are formed; and, as the *principia proxima* of vegetable substances are nearly the same, it is not surprising that the products in their reunion, after separation, should be similar. Modern chemistry employs less violent means, and new compounds are not so frequently produced. By these more gentle means, also, the analysis of mineral waters is much more accurate and satisfactory.

This science has, however, since the discovery of new gases, been very successfully employed in investigating the nature of the animal solids and fluids. A new era may be thus marked in our chemical physiology. They were not neglected by the French chemists, particularly the Rouelles, Homberg, and others; but we have only of late witnessed the happy results of more accurate, more scientific investigation. Since the period of Plenck, whose *Hydrology* is still an excellent work, we have received considerable satisfaction from Berthollet, Fourcroy, Vauquelin, Pearson, Hatchett, and many chemists of the new school.

To teach chemistry cannot be our object; we must treat of it as the handmaid, the assistant, of physic and the physician, and the chief details must be sought in the different articles. Yet, perhaps, we may here, with advantage, sketch the outline of the science; point out the mutual dependencies of each part, and supply what omissions may have already occurred. We must, however, speak chiefly of medical chemistry; for we anxiously wish to avoid stepping beyond the line of medicine, and to render this dictionary strictly, and, as far as possible, exclusively a medical one.

In teaching chemistry, modern authors have begun with elements, and proceeded to their compounds. We thus soar, perhaps, too far above common comprehensions, and certainly beyond the youthful intellect. We shall prefer the division of Dr. Black, originally that of Dr.

Cullen; and divide the objects of chemistry into salts, earths, inflammables, metals, and waters, adding the airs, vegetable and animal substances. We obtain, however, the bases of every body most pure in the form of air, so that we shall premise a short abstract of the properties of the different gases. Of caloric we have already spoken: of light, as a chemical principle, we know little, and still less of its real influence in the animal economy; yet, under that article, we shall add a few observations on the subject not wholly uninteresting.

Under the article AIR, in the First Part, we have mentioned the general properties of the different kinds of this invisible fluid, as well as of the medical properties of each species. We must now speak of air chiefly in a chemical view; and though, perhaps, in this and some other parts of the present article, we may seem to deviate from our professed intentions of confining ourselves to medical chemistry, such is the rapid progress of the science, and so much closer is its connection with physiology advancing, that, even while we are writing what may at first appear irrelevant, will become of the greatest importance.

We speak first of *oxygenous gas* as the least compounded form of air; and though, as we have said, the aerial form is the purest in which the different bases can be represented, yet it is doubtful whether this gas has any basis, and whether it is not strictly and purely caloric. It combines, under different degrees of temperature with all the gases or their bases, with inflammables and with metals, but not with earths or alkalis. The temperature required for the union is different; and when it is in so high a degree as to dissipate the body in vapour, inflammation, strictly so called, is produced. By the French chemists, the union of oxygen with different bodies is styled combustion, but in a loose, and, we think, an unscientific sense. This gas constitutes 0.22 of atmospheric air, and its specific gravity is 0.00135.

Oxygen combines with bodies in different proportions. With nitrogen, it forms atmospheric air: in larger proportions, successively, nitrous, nitric oxide, and nitric acid. With hydrogen, water: and, as has lately been rendered probable, in a larger proportion, muriatic acid. With carbon, it forms plumbago, charcoal, gaseous oxide of carbon, carbonic acid, and carbonic acid gas. With sulphur, oxide of sulphur, sulphureous and sulphuric acid. With phosphorus, oxide of phosphorus, phosphorous, and phosphoric acid. With carbon and hydrogen, it forms what are styled the hydrocarbonats and the vegetable acids; and, with the addition also of nitrogen, it forms animal substances. Oxygen unites with metals, forming what former chemists styled calces, now oxides. From these it is separated by phosphoric salts, and, indeed, by animal substances of every kind: a fact of importance in explaining the action of oxygenated remedies. It is separated also from almost every compound by light: a circumstance to which we shall return in that article.

*Nitrogenous or azotic gas* constitutes 0.78 of our atmosphere, and may afford the portion that we breathe with peculiar pleasure, and by which the process, styled animalization, may be chiefly assisted; it is probably absorbed in respiration. Its specific gravity is 0.00115, and some very delicate vegetable blues are rendered green by it. Vegetation, respiration, and combustion, are at once

checked by this gas when unmixed; and azote is the distinction of animal substances. It constitutes, with oxygen, nitrous acid, and is the chief ingredient in ammonia. It refuses to unite with water, and dissolves phosphorus and carbon in small quantities.

With oxygen it forms atmospheric air, and in succession nitrous oxide, nitrous gas, and nitric acid; with hydrogen, ammonia; with sulphur and phosphorus, sulphurated and phosphorated nitrogen gas. With carbon, nitrogen, and oxygen, it forms animal substances; should the oxygen be in excess, the result is animal acids.

With the proportion of oxygen, which forms nitrous oxide, viz. 37 of oxygen and 33 of nitrogen, it will support flame, and suffers no diminution when mixed with oxygen gas. It does not change even the most delicate vegetable colours, for in this state it recedes from its alkalinity, nor does it combine with alkalis. With atmospheric air, it is highly grateful when breathed, which supports the idea formerly hazarded, that azote, so far as it can be safely introduced, is pleasing and salutary. Water absorbs one half the bulk of nitrous oxide.

The nitrous gas contains 44 parts of oxygen, but does not change vegetable colours. Its specific gravity is 0.001343. It forms, with oxygen, nitric acid, and water absorbs 0.118 of its bulk. It supports neither vegetation nor respiration, and only in a few instances combustion.

*Hydrogen gas*, the inflammable air of Priestley, is very light, for its specific gravity is only 0.000094. It is highly inflammable, and burns when oxygenous gas or atmospheric air is contiguous; or detonates, when mixed with them, on the application of a burning body. It extinguishes flame, and will not support respiration. It dissolves sulphur, forming hepatic gas; and united with phosphorus and carbon, it forms gases highly fetid.

Hydrogen, with oxygen, forms water; with a less proportion it has been lately thought to produce muriatic acid; with nitrogen, ammonia; with sulphur and phosphorus, hepatic air and sulphurated hydrogen. With carbon and oxygen it produces the hydrocarbonates and vegetable substances; with carbon, nitrogen, and oxygen, animal substances and animal acids. Water is composed of 14.42 of hydrogen, to 85.58 of oxygen; ammonia of four parts of nitrogen, and one of hydrogen.

Carbonic acid gas was formerly known by the name of fixed air, and its discovery was the germ of the whole of pneumatic chemistry. Its basis, carbon, in its purest form, is the diamond; and 17.88 of carbon with 82.12 of oxygen, forms the gas. It is the chief basis of vegetable, though it occurs also in animal substances.

With oxygen and iron it forms plumbago, and with a larger proportion, successively, charcoal and gaseous oxide of carbone; with metals, what are styled, in the new language, carburets. With oxygen and hydrogen, it forms the hydrocarbonates, alcohol, ether, oils, wax, resins, camphor, starch, sugar, jelly, tannin, and all the variety of vegetable acids, with the mucous, lactic and sebaceous acids. With nitrogen, oxygen, and carbon, it forms the various gums and resins, cork, gelatin, albumen, fibrin, urea; the prussic, zoonic, uric, and amnic acids.

Common charcoal of wood contains 36.14 of oxygen the gaseous oxide of carbone, 74.11 of oxygen.

SALTS are either acid or alkaline. The *acid salts*, or *acids*, are mineral, vegetable, and animal; though various acids are not exclusively confined to the class in which they are arranged.

The mineral acids, or those usually styled so, are three, the vitriolic, the nitrous, and the muriatic; but the succinic, the boracic, and several others, have an equal claim to the title, as they are the productions of, or at least found in, the mineral kingdom. These acids unite with alkalis, earths, and metallic oxides so completely, that in the new compound, the properties of the component parts are wholly lost; while some of the weaker acids, particularly the carbonic acid gas, leave often an alkaline, urinous taste. These acids, like all others, owe their acidity to the oxygen they contain, united to separate bases, which give their peculiar properties; but this oxygen may be in excess, and the acid has then been styled oxygenated, or the particle (oxy) is added. The French chemists distinguish the acids with an excess of oxygen, by terminating their respective appellations with *ic*, as sulphureous and sulphuric. Their general properties have been already detailed.

The *vitriolic acid* is diffused so generally, as to be styled the universal acid; but many others can now dispute this honour, particularly the carbonic. In medicine it is of the highest importance, since, independent of its tonic powers when uncombined, its union with alkalis and metals furnishes a variety of useful remedies. Its basis is sulphur, and, from its apparent viscosity, it has been styled *oleum sulphuris*. When sulphur is inflamed, the oxygen is supplied by the atmosphere; and for this purpose it was formerly burnt under a bell, from whose sides it streamed into a receptacle below. It is now usually prepared in close vessels; and the oxygen is supplied by the addition of nitre, whose acid is in this operation decomposed.

Vitriolic acid will crystallize at 3° below 0 of Reaumur. With ice it produces an increased cold; with water considerable heat. With alkalis it forms the sulphat of potash, formerly the vitriolated tartar, the sulphat of soda (Glauber's salt), and the sulphat of ammonia (Glauber's secret ammoniacal salt).

The sulphat of potash is soluble in about sixteen parts of water, at 60° of Fahrenheit, which we shall afterwards call *cold water*, and five parts of boiling water. It is the least soluble salt, and on this account inconvenient in its exhibition, as it requires so much fluid. One hundred grains contain 30.21 of acid; 64.61 of alkali; and 5.18 of water. The sulphat of potash, of commerce, is the residuum after distilling nitrous acid, separated from nitre by means of the vitriolic. In extemporaneous prescription, it is only decomposed by barytes or any of its preparations. In some circumstances the nitric acid will displace the vitriolic; but this is of little importance to our subject, which is not strictly chemical. Mr. Chaptal found this salt in the analysis of tobacco.

The sulphat of soda is soluble in three parts of cold water, and in an equal weight of boiling water. It contains a large quantity of water entangled in its crystals, which occasions it to swell and effervesce when heated: 100 grains contain 14 of acid, 22 of alkali, and 64 of water. It is found in the ashes of the tamarix gallica; but the salt of commerce is the residuum, after preparing the muriatic acid. It is decomposed by pot-

ash, baritic salts, the muriat of potash, the acetite of soda, muriated lime, lime water, nitrated silver, acetated and nitrated mercury, and acetite of lead.

The sulphat of ammonia is seldom, if ever, used in medicine. It is produced chiefly by decomposing earthy or metallic salts with volatile alkali, and by the decomposition of nitric, muriatic, or carbonated ammoniacal salts by sulphuric acid. In extemporaneous prescription, fixed alkalis, barytes, and lime, the nitric and muriatic acids must be avoided in the same formula.

The basis of the *nitrous* acid is the nitrogen, which, with different portions of oxygen, forms nitrous oxide, nitrous gas, nitrous and nitric acids. The nitrous acid is brown, volatile, and suffocating. It assumes successively a blue, green, and yellow colour, by the addition of water; and in a state of vapour is absorbed by water, oil, and sulphuric acid. It consists of about three parts of oxygen, and one of nitrogen. The nitric acid consists of four parts of oxygen to one of nitrogen; is liquid, colourless, and transparent, but corrosive, tinging the skin of a yellow colour. It produces heat when mixed with water, and is deprived of a part of its oxygen by light; while the suffocating fumes of the nitrous acid are destroyed or suppressed by keeping it in the dark. When concentrated, it inflames oils, sulphurated hydrogen, and iron filings. The same effect is produced on zinc, bismuth, and tin, when poured on them in a state of fusion. It oxygenizes all metals, mucilages, &c. and is itself decomposed. This facility in yielding its oxygen, which is seemingly separated by the animal fluids, and is certainly so by the phosphoric salts with which they abound, has rendered it an useful remedy where oxygenation is required. Its utility in curing syphilis is not indeed established by extensive experience; but it evidently prevents the disease from growing worse, when from weakness, inclement weather, or accidental circumstances, mercurials cannot be persisted in.

From the chemical composition of nitrous acid, its resemblance to atmospheric air is obvious, and by the air it is evidently formed. In many places, particularly in India, South America, and Spain, nitre requires only lixiviation and purification. In France and other countries, its formation is assisted by animal putrefaction, vegetable fermentation, and the rubbish of old walls, containing a calcareous substance. It is not easy to say what particular office either part of the process serves. It seems designed chiefly to adapt the mass for the absorption of the ingredients of the atmosphere, for these are only requisite to form the acid. The alkali is supposed to be the product of the vegetable fermentation. This is, however, improbable; and we strongly suspect that it arises from the calcareous matter, as we shall soon consider.

It is in the form of nitre that this acid is offered to our notice; in the language of modern chemistry, nitrat of potash. As it occurs from the hand of nature, it is far from pure. A large proportion has often, as might be expected, a calcareous basis; and sea salt generally forms a portion of it. We find nitre also in many plants, particularly the parietaria and bugloss; in fact, in all those whose extracts are liable to ferment. We need not enlarge on the methods of purifying nitre. We receive it in the form of a neutral, crystallized in

prismatic octoedrons, terminated by dihedral summits. It is fusible on ignited coals, and its acid is decomposed. It does not deliquesce, but dissolves in seven parts of cold water, and its own weight of boiling: 100 grains of the crystals are usually said to contain 30 of acid, 63 of alkali, and 7 of water. This salt is cooling, and highly useful in all inflammatory diseases, those of the bladder sometimes excepted. Nitre is decomposed by alum, Epsom salt, tartar, spirit of vitriol, vitriol of zinc, copper, and iron. From the usual laws of affinity, it should be decomposed by Glauber's salt; but this takes place only in a slight degree, and at a temperature of 32°. Its chief utility in the arts for the process of making gunpowder is well known. It is the principal ingredient also in fulminating powder; but even modern fancy has not yet enrolled this among the articles of the *materia medica*.

*Nitrat of soda* is styled cubic, quadrangular, and rhomboidal nitre, from the form of its crystals, which, however, are not cubic, but rhomboidal. It is somewhat more bitter than common nitre, and grows moist in the air. Cold and boiling water equally dissolve about two parts of the salt: 100 grains contain, it is said, 28.80 of acid, 50.09 of alkali, and 21.11 of water; but by others the proportions assigned are very different, and Tromsdorff thinks that 100 grains contain 43 of acid, 32 of alkali, and 25 of water. It is generally the product of art, though it has been suspected in some mineral waters. We know not that it has been used in medicine; but should it be employed, the prescriber should recollect that it may be decomposed by potash, alum, Epsom salt, vitriolic acid, and the vitriols.

Nitrat of ammonia is the production of art, and its crystals are described as resembling needles; the taste is cooling, but it has been little attended to, and has never been employed in medicine.

The marine acid has hitherto resisted every attempt to ascertain the nature of its basis. Yet, from some Galvanic experiments, it is suspected that it may be water; and this acid is only water with a diminished proportion of oxygen. We shall first describe this acid and its properties in the common way.

When pure, it is colourless; but has generally a yellowish hue, and exhales white suffocating fumes. It is lighter than either of the other acids; but its most distinguishing property is the very great change it experiences from an excess of oxygen. Though this be undoubtedly the principle of acidity, yet when added to the muriatic acid in an over proportion, its volatility is increased, its acidity and power of attraction for alkalis weakened, and instead of reddening vegetable colours, it destroys them. It is procured from common salt by the addition of sulphuric acid, when it assumes a gaseous form; and in this state has been recommended for destroying infection, and purifying infected rooms. As these fumes are very suffocating, the vapour of the nitric acid has been preferred; and the discovery of each has occasioned a controversy which perhaps might have been spared, and which we must afterwards more particularly notice, though we shall not pretend to decide the dispute.

The most delicate test of the presence of muriatic acid is the nitrate of silver; for the metal when united with the muriatic acid is insoluble, but the oxygenated acid occasions no precipitation; so that if any doubt

arises, the acid should be previously exposed to the light, which separates in every instance the oxygen. The oxygenated acid forms, with different bases, fulminating powders, whose detonation is extremely violent, and takes place on trituration only, without heat. The use of the oxy-muriatic acid in bleaching is well known; and in its union with alkalis it furnished the active ingredient of De Morveau's box, which, on opening, diffuses round the person who holds it a pure atmosphere, which destroys infection. The ingredients are now altered. See CONTAGION.

The experiments lately alluded to are, however, too striking to be wholly passed over, since they offer such a clear simple view of the different operations of nature as will greatly elucidate many unaccountable phenomena. In attempting to ascertain the basis of this acid, even Berthollet erred, and Mr. Lambe was misled by a remote analogy; nor some months since should we have given a more favourable account of Girtanner's hypothesis, who derived it from hydrogen. On the 23d of April, 1805, Mr. W. Peel of Cambridge, announced, in the Philosophical Magazine, his discovery of muriat of *soda* from the decomposition of water by the Galvanic apparatus. In June he repeated his communication, and mentions his having formed water from its elements to repeat the experiment; but this water, from a little inaccuracy in the proportions, being acidulous, he neutralized the acid with lime, and distilled it. But, after the Galvanic process, he found muriat of *potash*.

By a singular coincidence, about the same time Pacchioni of Pisa made a similar discovery. His letter is dated the 9th of May, sixteen days only later than Mr. Peel's, and both speak of *recent* discoveries. Pacchioni's apparatus is not described; and at the first glance it excites a suspicion that *he* procured oxygen only in the decomposition of the water, while others have obtained, exclusively, hydrogen; but as both are ingredients of water, evolved separately on different sides of the pile, this occasions little difficulty. On separating the oxygen, he found the gold wire dissolved, and the oxygenated muriatic acid evidently produced. Water then is hydrogen, with its full proportion, perhaps, of oxygen. When the proportion of the latter is diminished, it becomes oxymuriatic acid; and, when still further, the common muriatic acid. Mr. Henry has repeated these experiments with some success, but suggests a source of fallacy, which leads us at least to hesitate. We shall have frequent opportunities of resuming the subject in different parts of the work, as in the articles MURIATIC ACID, MURIATS, and SEA SALT, when we shall give whatever the labours of chemists have added to the stock. Even while this sheet was passing through the press, we find in the Journal de Physique, vol. lxi. some experiments instituted by the Galvanic Society at Paris, which throw considerable doubts on the supposed discovery.

Muriat of potash has been styled the febrifuge salt of Sylvius, and, from one process by which it was prepared, the regenerated marine salt. Its crystals are cubic, but not regular; its taste pungent and bitter; and it dissolves in three times its weight of cold water. It is supposed by some authors to contain 29.68 of acid, 63.47 of alkali, and 6.85 of water. It is found occasionally in sea water, and in some mineral waters; but, when

wanted as a medicine, which scarcely ever happens, it is prepared by art.

Muriat of soda is the common salt so generally diffused not only in the earth, but by the ocean, of which it constitutes the chief ingredient. Should the suspensions just stated be confirmed, its source will be well understood: at present it is unknown. There is every reason, however, to suppose, that all the fossile muriat of soda has been deposited from an ocean which once covered the highest continents, perhaps the whole globe, when the principal inhabitants were fish, and where animals, now known only from their debris, were the tyrants of this watery world. Common salt is highly necessary to the health of men and many other animals; it is a condiment most congenial to their constitution, and though some are, from necessity, obliged to live without it, yet all find its advantages when it can be procured. In America, animals from a vast distance repair to those regions where the salt effloresces on the surface, which they "*lick*" with great avidity, and the spots are distinguished by this appellation.

Common salt is pungent, with a slight bitterness. It dissolves equally in cold and hot water, in a little more than twice its weight of the menstruum: 100 grains have been said to contain 33.3 of acid, 50 of alkali, and 16.7 of water. Its crystals are usually cubical, but they seem to be sometimes octoedral. It scarcely ever forms an article of extemporaneous prescription, except in the form of sea water. Barytes, lead, and sometimes iron, seem to decompose this salt, and are employed to separate the soda for the artist; but could have no extemporaneous effect in mixture, were it even necessary to combine them in a medicine. Vitriolic and nitric acids are, apparently, the only instances from which any inconvenience could arise. Potash would, however, have a similar effect; and some metalline salts, particularly nitrat of silver, would decompose it; but these are not likely to meet in a prescription.

Muriat of ammonia was originally prepared in Egypt from the dung of camels, and is met with in commerce in round cakes, concave on one side, and convex above, from the shape of the glasses into which it is sublimed. When in conical masses, it is debased by other salts, particularly earthy ones. Its taste is acrid and pungent, with a flavour not very distant from the urinous alkaline. It dissolves in about three times its weight of cold, and about an equal weight of boiling, water; and, during its solution, produces nearly 32° of cold. Its crystals are four or six sided pyramids, generally aggregated in a plumose form, and it is said to consist of 42.75 of acid, 25 of ammonia, and 32.25 of water. It is not often used internally, yet we shall find that it is more commonly useful than has been supposed. Externally it is often employed; but, as it is decomposed by the sulphuric and nitric acids, by barytes, potash, soda, strontia, and lime, as well as by different salts composed of these acids or their bases, and by some metalline salts, the practitioner should be very careful of the ingredients with which he joins this salt. It is soluble in little more than four parts of alcohol.

These are the acids which chiefly claimed the attention of chemists within the last twenty years. An acid from vegetables was indeed well known, and it seemed to be varied in its forms and its properties; but modern chemistry has only ascertained their different

sources, and their distinguishing affinities. We find also in the animal system a variety of peculiar acids which claim our attention, and in both vegetables and animals there are various substances denominated oxides, which, with the addition of oxygen, assume acid properties. These we shall not consider in the present article, unless they have become peculiar objects of our attention, by having been introduced into the practice of medicine.

The principal vegetable acid is the acetous, known chiefly in common life by the appellation of vinegar; but nature offers us also that of lemons (the citric), of apples (the malic), that of galls (the gallic), that of acetosella (the oxalic), that of benzoïn (the benzoic), that of tartar (the tartarous), and that of borax (the boracic acid, or sedative salt). With a little exertion we separate from cork, the suberic; from camphor, the camphoric; from sugar, the saccharine; from gum, the mucous: but these are, perhaps, more strictly oxides. Fire separates the pyrotartarous acids, the ligneous and the pyroligneous acids. The carbonic acid we have already noticed.

Of these, the chief acid, perhaps that from which every other with some modifications proceeds, is the acetous. The tartarous and boracic acids will indeed merit our particular attention, on account of their medicinal formulæ; but the malic, the citric, the oxalic, acids, do not essentially differ. The benzoic acid, Mr. Hatchett, in the Philosophical Transactions for 1805, (Part II.), considers, with some reason, as a production of fire; in his own strictly philosophical language, a *product* rather than an *educt*. The saccharine, the camphoric, the mucous, the suberic, are certainly modifications of the acetous acid; and the ligneous, the pyroligneous, and the pyrotartarous, acids, are only vegetable acids disguised by an empyreumatic oil.

We have thus confined our views to the acids of vinegar and tartar. The former is the product of fermentation, or of that new combination, which, by the "play of affinities" from the slow intestine motion of the particles of a saccharine, and afterwards of a spirituous, fluid takes place. See FERMENTATION.

The *acetous* acid, as offered to us by the spontaneous changes, in consequence of fermentation, contains a large proportion of mucilage. This is separated by distillation, or more certainly by freezing; but the mode which chemists have preferred is uniting it with copper or lead, and distilling it from these bases. In this way it undoubtedly acquires new properties, and, in the modern nomenclature, merits the title of *acetic* acid. It is then highly fragrant and volatile, confined only by the purest gold or crystal; and, in this state, combined with aromatics, it becomes a very useful and safe prophylactic, a preservative from the infection of putrid fevers. See INFECTION.

Acetous acid is formed of the vegetable principle carbon, united with hydrogen and oxygen; and this compound is not only the result of the gradual decomposition of saccharine matter in fermentation, but is produced more rapidly by the action of nitric acid on many vegetable bodies; this acid supplying the oxygen, which is otherwise absorbed from the atmosphere. Though very commonly a vegetable matter, its immediate principles are sometimes unexpectedly combined, and we

discover it in animal and mineral productions. It will be obvious that its acid is destroyed by earths and alkalis, but the tartarous neutrals are also decomposed by it. Vinegar dissolves sugar, mucilages, and gums, and mixes in every proportion with alcohol. It softens gum resins; and, triturating with vinegar, renders gum ammoniac and asafetida more readily soluble in water. It dissolves the peculiar acrimony of the alkaline plants, and consequently forms the best menstruum for squills, colchicum, &c. Medicated vinegars are very common, and foreign pharmacopœias offer a considerable number. See ACETUM.

Acetated potash was formerly styled *terra foliata tartari*, and *tartarum regeneratum*: a more modern appellation, scarcely disused, is the diuretic salt. It is a deliquescent salt, and not adapted either for powder or pills. It may be decomposed by tamarinds and almost every acid, even the citric and phosphoric, and by almost every variety of neutral, either alkaline, earthy, or metallic. It is soluble in an equal weight of water at 60°. The preparation is difficult and uncertain.

The acetated natron has been styled the *sal vegeto minerale*; but it has never been employed as a medicine, and even its chemical properties have not been properly investigated.

The acetated ammonia was formerly styled *Mindereus spirit*. It is a deliquescent salt, and we receive it usually in a liquid form, but seldom of a certain strength; though a medicine given in doses of half an ounce or an ounce does not require any minute accuracy. When procured in a solid state, its crystals are long, slender, flattened, and of a pearly white colour: they melt at 170°, and sublime at 250°. It is decomposed by fixed alkalis, lime water, the acids of lemon, phosphorus, and tartar, as well as the three strong mineral acids; by alum, Epsom salt, nitrated silver, muriated iron, acetated lead, and the vitriols.

The *acid of tartar*, in common language, is the cream of tartar, which is the deposition from wine, purified from the oily and colouring matter, and crystallized in irregular masses, formed by a confused mixture of needle-like crystals. In this state it is gritty between the teeth, and of a harsh unpleasant sourness; soluble in sixty times its weight of cold, and half the quantity of boiling water. It is not, however, a pure acid, but contains from twenty-three to thirty-three hundredths of potash. The purification of tartar is kept a secret; but it is probably effected by the admixture of pipe clay, since, by repeatedly washing the crystals of tartar, an earth of this kind remains. It has been a pharmaceutical problem to render cream of tartar more soluble in water, and borax has been employed for the purpose; but the latter is by this means decomposed.

The real acid of tartar is not deliquescent, and for this reason it is entitled the dry powder of lemonade. It is not the reputed salt of lemons, which is in reality the salt of wood sorrel, though it is supposed to add not a little to the bulk of this expensive preparation. The powder of lemonade is prepared by mixing a drachm of the essential salt of tartar with six drachms of sugar, and a drachm of the eleosaccharum of oil of lemons. It is obvious that alkalis and earths will destroy the acid, but the eyes and claws of crabs are not purely calcareous; and though with chalk it forms an indissoluble salt, with magnesia, on the contrary, it forms a soluble one.

But whatever its affinities are in the moist state, in a dry powder they are not exerted; and the acid of tartar forms the basis of a salt, from which the carbonic acid is readily separated in solution. We hinted at this mixture when we spoke of the exhibition of this acid; and the preparation consists of one drachm of the acid, with two of kali, or three of natron, adding a little sugar according to the taste. This acid decomposes all the salts, whose basis is the vegetable alkali. It decomposes also muriated lime and barytes, nitrated silver, muriated iron, acetated and nitrated mercury, acetated lead, and all the vitriols, as well as soaps of every kind.

The tartarised kali is the tartarised tartar of former authors, the soluble tartar of pharmacists, and is usually prepared by saturating the superabundant acid of the cream of tartar by adding kali. It is soluble in alcohol, and in four parts of cold water. It is decomposed by all acids and by acid fruits; by lime, barytes, strontia, and magnesia; partly by the sulphats of potash, soda, alumine, and magnesia; and by the muriats of barytes, lime, and ammonia; by cubic nitre, and the most common metallic salts.

The tartarised soda has been styled *sal Rupellensis*; but as the crystals of tartar are saturated with the soda, it is obvious that this is properly a triple salt, and has been justly called by the Edinburgh college, *tartris potassæ et sodæ*. Its crystals are very large and regular, in the form of prisms, of eight nearly equal sides, divided longitudinally almost to their axis. It is bitter, soluble in about five parts of water, effloresces, but does not deliquesce, in the air, and consists of about 54 parts of tartrite of potash and 46 of tartrite of soda. All acids decompose it; even the acid fruits, alum, muriated lime, Epsom salt, nitrated mercury, acetated lead, and the vitriols, have the same effect.

Tartarised ammonia seems not to have been examined: it certainly has not been employed as a medicine. Its crystals are tetrahedral pyramids, with obliquely truncated summits.

Borax is a natural production, which nature offers, partly saturated with soda, as the acid of tartar is with kali. The crystals of borax are hexangular prisms; of which two sides are broader than the others, terminated by white triangular pyramids. The taste is styptic and urinous; it colours vegetable blues green, is soluble in 18 parts of cold water, and in 6 of boiling. It slightly effloresces in the air, swells with the loss of nearly half its weight from heat, and becomes a porous friable mass, melting in a greater heat to glass. It is decomposed by all acids and alkalis, by the sulphats, nitrats, muriats, phosphats, and fluats, of all the earths, and of ammonia. The boracic acid forms 39 parts, soda 17, and water 44.

Its acid was styled by Homberg, who discovered it, the sedative salt, from its supposed soothing power in fevers. It appears in small, shining, laminated crystals, and its specific gravity is 1.48. It vitrifies in the fire; is soluble in water and alcohol, imparting to the latter the property of burning with a yellow flame. Of borax we have already spoken; but of the borats we know little, and they certainly form no part of the materia medica.

The citric and oxalic acid are employed in medicine; but their compounds, the citrats and the oxalats, except in one instance, the citras potassæ, do not claim the phy-

sician's attention. We must not, however, wholly omit them or the other acids, as in the rage for novelty they may in turn share our regard.

The *acid of lemons* is with difficulty separated from its mucilage, so as to be reduced to the state of a limpid solution or a crystalline form. Various attempts have been made to concentrate it by freezing, or to combine it with spirit of wine, from which the mucilage is easily separated. The most successful plan was suggested by Scheele, to combine the acid with chalk; from which, as the salt is nearly insoluble, the mucilage may be readily washed: the citric acid is then separated by adding the sulphuric. It is one of the strongest of the native acids; and cannot, like the greater number of the others, be converted into the oxalic by means of the nitric acid. Its crystals are octohedral prisms, truncated on their solid angles. The citric acid unites with alkalis, earths, and even metals. With the fixed alkali it is supposed to sit more easily in the stomach than any other neutral; which, if true, may be owing to some remains of the carbonic acid gas separated from the alkali, and entangled in the fluid: but all neutrals possess, in a certain degree, an anti-emetic power. The citric acid decomposes all tartarised neutrals.

The *malic acid* is not peculiar to apples, from whence its name is derived, but is found in all unripe fruits, and may be converted into oxalic acid by the nitric. It is separated from the mucilage by combining it with chalk, and then adding the acetite of lead. The malate of lead thus formed is decomposed by the sulphuric acids. This acid is frequent in a variety of plants, particularly the succulent ones, and in common parsley: and Vauquelin tells us, that when the juice of a plant furnishes a copious precipitate with oxalate of ammonia, and a flocculent one with acetite of lead, it undoubtedly contains a malate of lime. By fire, this acid is destroyed or converted into carbonic acid. The malates of alkalis are deliquescent, but the malate of alumine is with difficulty soluble: it unites with iron and zinc: the chalybeate salt does not crystallize; that with zinc forms fine crystals.

The *oxalic acid* which nature offers us combined like tartar, in part with an alkali, has a penetrating sour taste. It effloresces in the air; and is soluble in twice its weight of cold, and half its weight of boiling, water. Like all the weaker acids, it dissolves the metallic oxides rather than the metals themselves; and it combines with the more common earths. With lime it forms a salt so insoluble, that it becomes the surest test of calcareous earths and its compounds; though Brugnatelli suspects its infallibility.

The *acid of sugar* is one of those products from the vegetable oxides by means of the nitric acid which we have already mentioned. Not only sugar, but mucilages, mild oils, and flour, assume by this intermede the form of an acid; and this acid is invariably the oxalic.

The *gallic acid* seems to collect its oxygen from the air, since long exposure to the atmosphere is necessary to its production. The taste is acid and astringent; it effervesces with lime, and reddens the blue vegetable infusions. The salt requires twelve times the quantity of cold water, and one and a half of warm. It dissolves also in alcohol, in equal quantities when hot, but requires four times its weight when cold. It forms oxalic with nitrous acid; and the acid, when sublimed,

resembles in obvious qualities the benzoic. The gallic acid is totally distinct from the tanning principle; with which, as both are often united, it has been confounded.

The *acid of cork* is sharply acid and bitter. It deliquesces in the air, and becomes brown by the sun's light. It is distinguished from the acid of camphor, by turning the solution of indigo green; from the gallic acid, by its yellow precipitation; and from the malic, by its solid form. It does not burn or smoke on hot coals, like the tartarous; gives a green hue to a solution of nitrat of copper, without occasioning any precipitation; and does not attract lime so strongly as the oxalic acid.

The *benzoic acid* appears very generally in the vegetable chemistry; and we have mentioned it as the acid which gives the balsams their distinguishing properties. Since that article was printed we have received Mr. Hatchett's valuable observations on this and some other acids; and we have thus a striking proof, if any other was wanted, of the utility of frequently returning to the same subject in a progressive work like the present, if we would, as we profess, render it a picture of the science at the present moment. The properties of the benzoic acid, as generally recognised, occur under the article BENZOINUM. We must now add, however, the formula adopted in the last edition of the Edinburgh, from the Prussian, Pharmacopœia; not as a chemical refinement only, but as better fitting it for being reduced to a powder, should it be ever employed as a medicine. Twenty-four ounces of gum benjamin are triturated with eight quarts of water for half an hour; the water is strained off, and the gum again triturated with three quarts of water and strained. The strained liquors are mixed and evaporated to a quart, to which diluted sulphuric acid is gradually added while any precipitation appears. The precipitated acid is dissolved in boiling water, strained while hot, and set aside to crystallize. The crystals, which are less beautiful than the flowers, must be washed in cold water, and preserved in a dry phial.

The *camphoric acid* has not been used in medicine, and the properties of its neutral salts are little known. Its crystals resemble the muriat of ammonia, and are, with difficulty, soluble in water. It is not, perhaps, very different from the benzoic acid. It burns without any residuum; does not precipitate lime from lime water, nor produce any change in the sulphuric solution of indigo.

Two animal acids yet remain, the phosphoric and prussic; for the uric acid we shall not again consider, unless additional information lead us to resume the subject. See CALCULUS.

*Phosphoric acid* is produced from phosphorus (see INFLAMMABLES) by burning, but is not in that process saturated with oxygen. It is in a more perfect state when prepared, as usual, by nitric acid. The phosphoric acid when pure is not corrosive, and has no smell; its specific gravity is three times that of water, and it may be concentrated to dryness, when it is styled the glacial acid of phosphorus. It combines with alkalis, and the alkaline earths; but its salts are seldom soluble. With magnesia, if the acid is in excess, the salt is soluble; and were not phosphorus a suspicious medicine, we should recommend this salt to a cautious trial. The only neutral employed by the physician is

the phosphat of soda; a salt almost tasteless, though sufficiently active as a cathartic for children, perfectly safe, and highly useful. Its crystals are rhomboidal, and they effloresce in the air. It is decomposed by alkalis, the mineral acids, tartarous neutrals, alum, muriated lime, Epsom salt, muriated barytes, and almost every metallic salt.

The *prussic acid* is an ingredient in the vital fluid, and may be obtained by distilling blood with the nitric acid. It has an acid taste and suffocating smell; combines with alkalis and metals; and has lately been discovered in the vegetable kingdom as a component part of bitter almonds, the cherry, peach, and apricot kernels, and perhaps laurel and peach leaves. Berthollet supposes its basis to be composed of hydrogen, nitrogen, and carbon; but the proportions are not known. It has in no form been yet employed in medicine, except in the (now neglected) black cherry water.

Two anomalous neutrals yet remain, which, to complete the subject, we shall here consider, viz. the *hydrosulphurat of ammonia*, introduced into the last edition of the Edinburgh Dispensatory, and the *sal polycresum Glaseri*. Tromsdorf seems first to have remarked that sulphurated hydrogen combines with different bases like an acid. The hydrosulphurat of ammonia is prepared by decomposing sulphurat of iron with muriatic acid. When the acid separates the iron from the sulphur, the latter, with the oxygen of the water, forms sulphuric acid; while another portion of the sulphur forms the hydrogen, forming sulphurated hydrogen gas, which is afterwards combined with the ammonia. This is the preparation of the salt recommended by Mr. Cruickshanks in diabetes, which he styles hepatised ammonia; and though experience has not established its utility in this complaint, there is great reason for supposing that it may be useful in some others, particularly in phthisis. It must be, however, employed with caution, since it produces vertigo and other unpleasant symptoms.

The *sal polycresum of Glaser* is only a combination of an imperfect sulphureous acid with potash. It is easily decomposed; and though it was once a celebrated remedy in Germany, is now rarely used.

ALKALIS are salts of an opposite nature, and very rarely found native; never, perhaps, pure. They are either the vegetable, the mineral, or the volatile: but the two former are not exclusively derived from that kingdom which gives them their distinguishing appellation; as the vegetable alkali has been found in some granites of a very early formation, if not primordial, and the mineral in numerous vegetables.

Alkalis were long supposed to be elementary substances; but a few years since M. de Morveau announced that he had discovered the vegetable alkali to consist of hydrogen and lime; the mineral of the same principle and magnesia. His few experiments were, however, inconclusive; and would, perhaps, not have occurred to our notice, but for the facts pointed out when we spoke of the decomposition of the muriatic acid. The whole is strongly prepossessing from its simplicity.

The alkalis in the earlier chemical works were by no means such as the modern chemistry recognises by this title. They are, in the modern systems, considered as imperfect neutrals, neutralised by the carbonic acid or fixed air, which, as we have hinted, does not deprive them of their alkaline properties; nor, indeed, when

supersaturated with this acid and become acidulous, do they wholly lose their alkaline or urinous taste. We have nothing further to add on this subject. See ALKALI.

**EARTHS.** Chemistry has lately been enriched by numerous additions to this class of bodies, and medicine has also made a few acquisitions. Though earths should not appear to be the bases of alkalis, yet many approach alkalis very nearly in numerous properties. In general, earths are insoluble in water, at least when joined with carbonic acid; and in this state also they are without taste and smell. They are fixed, and unalterable in fire, assuming the form of a dry powder, and their specific gravity rarely exceeds 4.9. The five earths employed in medicine are, the barytes, strontia, lime, magnesia, alumine; the five others are the yttria, glucina, zircona, agustina, and silica. These are arranged nearly in the order of what may be styled their alkalinity.

*Barytes* is a greyish white porous body, possessing even a greater pungency than lime. It tinges blue colours green, and, as we have said, destroys animal substances. Its specific gravity is nearly 4, and it is not affected by the strongest heat. It is slaked in the air, and by water, like lime; and when dissolved in hot water it crystallizes on cooling, in needle-like crystals, composed of 53 parts of water, and 47 of barytes. Water dissolves 0.05 of this earth, and resembles in taste and properties lime water. Boiling water dissolves half its weight. It will not unite with oxygen, azote, hydrogen, carbon, or charcoal, but joins readily sulphur and phosphorus. (See BARYTES).

*Strontia* resembles barytes in every circumstance, except that the salts it forms with acids have somewhat different properties; and it will probably be found that potash and soda, barytes and strontia, lime and magnesia, are very nearly and respectively connected. The specific gravity of strontia is about 3.7. One part of strontia requires 162 parts of cold water, but boiling water dissolves it more freely. In cooling, the earth is deposited in thin quadrangular plates, which are often parallelograms: occasionally they adhere and form cubes, containing about 0.68 of water. It is not poisonous; and though it has been tried in medicine, it does not seem to possess any peculiar medicinal powers.

*Lime* is an earth well known, and has already been particularly noticed (see CALX). We may add here, for the sake of the connection, that its specific gravity is about 2.4, and that it is soluble in 450 times its weight of water. Its neutrals are supposed to be astringent. It combines, in the form of lime water, with the oxides of mercury and lead; but we know not that these compounds have been employed in medicine.

*Magnesia* was first pointed out as a distinct earth by Dr. Black. Its properties are less strikingly alkaline than the preceding earths, and it does not melt in the strongest heats that can be employed; nor does it become acrid by calcination, though the air which it loses in the fire is rapidly regained on exposure to the atmosphere. If, therefore, the calcined magnesia is not carefully kept from the air, it soon differs little from the common earth. Its specific gravity is 2.33, and its compounds, with acids, are soluble; yet even with the vegetable acid, the neutral is deliquescent and not pleasing to the taste. The fossils in which it predominates are soft and unctuous to the touch.

*Alumine* is an earth of the highest importance in medicine, since its sulphat, the common alum, is a very valuable remedy; and the boles, in which it is often a principal ingredient, are useful in sheathing membranes deprived of their mucus. The earth is soft to the touch, and adheres to the tongue, in consequence of absorbing its moisture. Its specific gravity is 2.0. It absorbs water, and is diffusible through it: but alone it is wholly insoluble; and in fire infusible. It unites with alkalis, and many different earths.

Of the remaining earths our account will be necessarily short, as they are useless in medicine.

*Yttria* appears in the form of a tasteless, white powder. It is insoluble in water, and does not change vegetable blues. It refuses all union with fixed alkalis, but unites with the carbonate of ammonia. With acids it forms salts of a sweetish but somewhat austere taste, and in fire it is unaltered.

*Glucina* is obtained in white, light masses, adhering strongly to the tongue, unaffected by fire, and insoluble in water. This earth unites with all the alkalis, with acids, and with sulphurated hydrogen.

*Zircona* appears also as a white powder, soft to the touch, without taste or smell; of a specific gravity equal to 4.3. Though infusible by heat alone, when surrounded by charcoal its particles unite to a flinty hardness. It combines with carbonated alkalis, and is soluble in all the acids, though insoluble in water.

Of *agustina*, the existence as a distinct earth has been disproved. If Tromsdorf's experiments may be trusted, though the results have not been supported by other chemists, it resembles alumina, and refuses to unite with all alkalis. It hardens when heated without acquiring any taste, and its salts are tasteless.

*Silica* is well known by its common appellation, flint. It melts with alkalis, forming the well known and useful compound, glass; but it is insoluble in acids, and wholly useless in medicine. It occurs in vegetable substances; and must consequently admit of such a minute division that we may expect to find it also in the animal fluids. It occurs, we find from late experiments, in the Bath waters; but we have no reason to think that it contributes to their medicinal virtues. Its source is unknown; but if potash is only lime united to hydrogen, as this salt dissolves flint, on the separation of the hydrogen, the latter will necessarily form distinct concretions, in which state we find it. We regret that this system of De Morveau's is not better established, since it elucidates so clearly various facts in mineralogy, many more indeed than we dare hint at. Silica combines with barytes, and, when recently formed, unites with about 1000 parts of its weight of water.

**INFLAMMABLES.** These are sulphur, phosphorus, the various kinds of pitcoal, charcoal, and amber. Of these the two former only are medicinal, and to them we must return; but to preserve the connection we shall give a very short outline of the chemical properties of each.

*Sulphur* is known to be a yellow substance, brittle, fusible, electric, insoluble in water, of the specific gravity of nearly 2.0. It sublimes at 170°, melts at 185°, burns with a pale blue flame at 300°, and with a bright white flame at 570°. It combines with different proportions of oxygen, and occurs in a variety of minerals, particularly metallic ores.

*Phosphorus* is a concrete oxide, generally prepared from urine or bones, of the consistence of wax, of a reddish colour, which it loses by being kept in the dark. It is soluble in essential, and with some precautions in expressed, oils. When the oil of cloves is employed, a flash of light follows each time the bottle is opened. Phosphorus in the dark emits a pale light, but at about 100° of Fahrenheit melts and burns with a vivid flame and violent heat. It is brittle under 32°, and its fracture is vitreous and somewhat lamellated. It unites with oxygen, but attracts it only when nitrogen or some other intermede is added. This union would appear to be a mixture, but that phosphorus attracts oxygen from the oxy-muriatic acid. With oxygen, as we have said, the phosphoric acid is produced. The union of phosphorus with oxygen takes place with considerable violence if the ingredients are struck only. Nitrate of silver, or oxygenated muriat of potash, forms, with phosphorus, the most violent fulminating powders, in consequence of percussion only; but even common muriates, with heat, will have the same effect. This is a fact of more importance, as phosphorus has been lately given internally; but great inconveniences have arisen from its exhibition, which seems sometimes to have proved fatal. Its specific gravity is 2.0382, taste acid, smell alliaceous. It is raised into vapour by a heat of 180°, and boils at 534°.

Of charcoal and pitcoal (see CARBO) we have spoken at sufficient length, as they are not substances very often employed in medicine. Respecting amber, usually arranged under the inflammables, we have nothing to add. See AMBER.

*Metals* are opaque, brilliant bodies, considerably hard, very frequently malleable in different degrees, though some are flexible and elastic. They make no impression on the organs of smell or taste, except in some instances when rubbed. They are the best conductors of electricity; and during the oxidation of some of these bodies, the Galvanic influence becomes powerfully conspicuous. All may be melted by heat, and the greater number are exhaled in vapour.

Metals are divided into those which, by the addition of oxygen, become acid, and those which are oxidised, without showing any acid properties. Of the former kind arsenic, tungstein, molybdenum, chrome, and columbium. Of the latter, gold, platina, silver, copper, iron, plumbago, lead, tin, zinc, mercury, tellurium (sylvanite of Kirwan), antimony, bismuth, manganese, nickel, niccolanum, cobalt, uranium, titanium, palladium, osmium, and iridium. We shall shortly mention their properties in the same order, excepting only those generally employed in medicine; and their medical effects depend so intimately on their chemical treatment, that it would neither be easy nor advantageous to separate the different parts of the subject.

*Tungstein* is a semimetal of a gray colour, fusing with great difficulty, oxidisable in the air by heat, and afterwards acidifiable. In the state of an oxide it is yellow; in that of an acid, white. The former gives to glass a blue or brown colour.

*Molybdenum* has a very slight metallic splendour, and a low specific gravity. It is oxidised by sulphuric, and easily acidified by nitric, acid. The acid is white and styptic. Though the specific gravity of the metal is but 6, that of the acid is 8.4.

*Chrome* is of a whitish gray colour, very brittle, and with difficulty fused or oxidised. Neither the sulphuric nor muriatic acids dissolve it; but the nitric changes it first into a beautifully green oxide, and afterwards into an orange yellow acid.

*Columbium* is little known. It was discovered in an American fossil by Mr. Hatchett, and its acid is a white powder, insoluble in water.

Of the oxidisable metals, we shall omit, for the reasons mentioned, gold, silver, copper, iron, lead, tin, zinc, mercury, antimony, bismuth, and manganese.

*Platina* has not yet found its way into the materia medica, nor is it likely soon to become a medicinal substance. It is of a gray colour, approaching to black, when polished. Its specific gravity is about 21, and it yields to gold only in ductility, and to iron in hardness. It is fused in 160° of Wedgewood, 21.877° of Fahrenheit, could Fahrenheit's scale be continued to this point. It is a good conductor of electricity and Galvanism; is oxidised by the former, producing a gray powder. It is oxidised and dissolved by the oxy-muriatic, but more certainly and quickly by the nitro-muriatic, acid.

*Plumbago* is a carburet of iron, seldom pure, and requiring a high degree of heat for its union with oxygen.

*Tellurium*, which Mr. Kirwan styles *sylvanite*, is of a bright lead colour, but brittle and crystallized in lamellæ. Its specific gravity is about 6.1. It soon melts and sublimates. It burns with a greenish flame and a white smoke, resembling the smell of radishes. Its oxide melts into a straw coloured radiated glass. It is soluble in sulphuric, nitric, and nitro-muriatic acids.

The colour of *nickel* is between that of tin and silver, nearly 9 in specific gravity; when pure, extremely ductile and malleable; infusible, and with difficulty oxidisable in the air: yet it yields to the nitrous and nitro-muriatic acid only, tinging them of a brilliant green. It combines with phosphorus, sulphur, and the different metals. Its oxide is of a light clear green, giving to glass a brown and orange, in some instances a red, hue; but reducible by fire only. It is strongly attracted by the magnet, and can assume polarity. Richter. Niccolanum, lately discovered by the same author, very nearly resembles nickel.

*Cobalt* is a metal so brittle as to be capable of being reduced to powder. Its grain is fine, its colour of a reddish gray, and its specific gravity nearly 7.8. It is oxidated previous to its fusion, and requires a high degree of heat for its melting. It yields to all the acids, and unites with phosphorus and sulphur. Its oxide is of a deep blue, and gives this colour to glass. In the arts it is styled zaffre, or smalt.

*Uranium* presents a mass of small globules slightly united, of a pale brown, sometimes of a gray, colour. Its specific gravity is 6.44. It is very infusible, but yields to several of the acids, and unites with phosphorus. Its oxide is yellow, colouring glass of a greenish yellow an emerald green, or brown of different shades, and is very soluble in carbonated alkalis.

*Titanium* occurs in hard friable masses, of a crystalline appearance; internally of a bright red. It is very infusible, and yields only to the principal mineral acids by boiling. Its oxide is a deep red, blue, or white.

Of iridium, osmium, and palladium, three metals, if truly distinct ones, found in platina, we yet know little,

and of course shall not enlarge this (already too extensive) article, by enumerating properties imperfectly known. What has been discovered occurs in the Philosophical Transactions for 1804 and 1805.

The VEGETABLE SUBSTANCES which have claimed the chemists' attention are, sap, mucilage, gum, oils, resins, gum resins, caoutchouc, balsams, fœcula (starch), gluten, sugar, albumen, various acids, tannin, alkalis, wax, honey, and aroma. These substances, as we have stated in the beginning of this article, consist of carbon, hydrogen, and oxygen. The tannin, lately introduced to our notice, has been lately examined with peculiar attention in the Philosophical Transactions for 1805, by Mr. Hatchett. He has produced it with a variety of substances artificially, viz. by the action of nitric acid on any carbonaceous substance, vegetable, animal, or mineral; secondly, by distilling this acid from common resin, indigo, dragon's blood, &c.; thirdly, by digesting common resin with gum elemi, asafœtida, camphor, &c. which then yield a principle very nearly resembling tannin to alcohol.

The ANIMAL SUBSTANCES which have been the objects of the chemist are, the blood, the gastric and pancreatic juices, the milk, the sebatic acid, the bile, the urine; the prussic, zoonic, formic, and bombic acids; the hard parts of animals; the humours of the eye; cartilages; brain; synovia; tears; mucus of the nose, &c.; cerumen of the ears; saliva; pus; semen; sweat; liquor amnii; eggs; hairs; feathers, and silk. These are more particularly the object of this work, and have been or will be considered in separate articles. We need scarcely repeat, that nitrogen, or azote, is the distinguishing principle of animal substances; and have already observed that their component parts are nitrogen, hydrogen, carbon, and oxygen.

The ultimate analysis of animal substances is peculiarly embarrassing, on account of the extensive combination of their elements, for the simplest agent produces numerous transformations; many of which, from the rapidity of their progress, escape us, and the last results are only obvious. The agent employed, most successfully, by Scheele, Bergman, and Berthollet, is the nitric acid; and the result, as we have often mentioned, is the evolution of azote in large quantities. The consequences are also a change in the acid; the copious production of ammonia; carbonic, oxalic, and malic acids; the transformation of one portion of these matters into fat; and of another into a yellow, bitter substance, the *bitter of Welther*.

The effects, however, vary according to the strength of the acid, the duration of its action, and the kind of substances examined by its means. These varieties have been lately the subject of MM. Fourcroy and Vauquelin's inquiries, and we shall take this opportunity of stating their results. The particular experiments have not yet been published.

The nitrous acid, from its first action, changed the muscular flesh into a yellow substance, with little taste, though still sensibly acid, and very imperfectly soluble. When the action was longer continued, the result was a matter equally yellow and acid, but very bitter, and very soluble. By a still longer continued action, the matter was soluble, inflammable, and fulminating, not only by heat but by percussion.

Indigo furnished a similar substance, and still more

copiously than muscular flesh. Haussman and Welther long ago discovered it; and MM. Fourcroy and Vauquelin attribute it to the separation of the azote, and to the combination of the hydrogen and carbon of the flesh, with the excess of oxygen furnished by the acid. They suspect that the yellow substance which tinges the bile, is equally produced by the separation of the azote and the union of the other ingredients, furnished probably by the blood. Yet this appears less probable; since the blood which is to furnish the bile is carried by a very circuitous course, after it has received the oxygen from the air, and the contents of the vena portæ abound seemingly more in azote than in oxygen.

While we are speaking of animal substances, it may not be uninteresting to add the experiments of those chemists on the *smut of wheat*. They found, in this degenerated corn, a green oil of the consistence of butter; phosphoric acid, in part combined with magnesia; some lime and ammonia; carbon, and a vegeto-animal substance, exactly like that which is produced in the decomposition of the gluten of wheat by putrefaction.

They consequently conclude, that the smut is the residuum of the farina, decomposed by a putrid fermentation; and suspect that it arises from an over proportion of animal manure, assisted by a hot and moist season at the period of its flowering, or the formation of the grain.

What may be further requisite for the different facts relating to medical chemistry, may be found under AFFINITY, q. v.

CHE'MICI, (from *chemia*). Called also *flatuarii*. Men who pursue the art of chemistry.

CHENALO'PEX, (from *χην*, a goose, and *αλωπηξ*, a fox). SHELL DRAKE. So called from its being of the goose kind, and crafty like a fox. See VULPANSER.

CHENOCO'PRUS, (from *χην*, a goose, and *κοπρος*, dung). GOOSE DUNG. It was formerly used as a powerful resolvent, diuretic, and anti-icteric. The green was thought the best; it was collected in spring, dried, and given from ʒss. to 3 i. for a dose.

CHENOPO'DIUM, CHE'NOPUS, (from *χην*, a goose, and *πους*, a foot). GOOSE FOOT, or SOW BANE; from its likeness to a goose's foot. Called also *atriplex sylvestris*, *pes anserinus*, *botrys*, *botrys Mexicana*, and *atriplex sylvestris latifolia*. It is reckoned among the uterines, but seldom used in the present practice. There are four species enumerated by the writers on the materia medica, viz. the *c. bonus henricus* and *rubrum* Lin. Sp. Pl. 318. *c. botrys* and *ambrosioides* 320. These are all oleraceous plants, possessing little medical power. The *c. anthelminticum* Lin. Sp. Pl. 320, has a fragrant though somewhat faint smell, and an aromatic taste. As the name imports, it is recommended for destroying worms. This forms the link between the oleraceous and the fetid species, which follows. See MERCURIALIS and BOTRYS.

CHENOPO'DIUM FETIDA, CHENOPO'DIUM VULVA'RIA. See ATRIPLEX FETIDA.

CHEOPI'NA, (from *χῆω*, to pour, and *πινω*, to drink). See CHOPINO.

CHE'RAS, (from *χῆω*, to pour out). It is so called during its discharge. See SCROFULA.

CHEREOFOLIUM. See CHEROPHYLLUM.

CHE'RMES, (from the Arabic term *charmah*, or *karam*). Also called *coccum scarlatinum*, *chermesinum*.

*linctorium* and *bapticum*, *alkermes*, *coccibadicum*, *grana kermes*, *coccum insectarium*, *quisquilia*, SCARLET GRAIN, and KERMES BERRIES.

*Kermes*, among the Arabians, and *καρκος*, among the Greeks, signifies a small worm; *grana arboris Ilicis*, *quibus punicea inficiuntur*.

An insect which much resembles the green house bug, lays its eggs on the *quercus ilex* Lin. Sp. Pl. 1420, the SCARLET OAK. The females of this kind have no wings. The colour of these berries, or rather insects, is like that of a blue plum; the red colour which they have when brought to us, is from their having been washed with vinegar. They are about the size and shape of juniper berries that are cut into two parts; the hole, in the flat surface, leads to the skin of the belly. When these insects are fresh, they appear full of minute reddish ova, and which, in long keeping, change to a brownish red colour. They are preserved by sprinkling with vinegar, which prevents the exclusion of the ova, and kills such of the animalcules as are already hatched, and would otherwise soon fly away. They are brought from France, Spain, Candia, &c. where they are gathered in May, and early in the mornings, while the prickly thorns, on which they adhere, are soft with the dew.

Geoffroy obtained an alkaline spirit from them by distillation. The fresh kermes, on expression, yield a red juice of a light, agreeable smell, and a bitterish sub-astringent, and somewhat pungent taste; but before it is brought to us, it is boiled with sugar into the consistence of a syrup. The dried grain, if not too long kept, gives out, both to water and to spirit, the same deep red colour, the same smell and taste, as is in the expressed juice. By evaporation, the watery tincture loses nearly all its smell and taste, but the spirituous retains both; and spirit extracts the active parts most completely.

They are grateful to the palate, esteemed cordial and astringent, and aphrodisiac, without any real virtue, or in any considerable degree. A confection, called *confectio alkermes*, was made of the juice of chermes berries, and once not unfrequently prescribed; it was invented by Mesue, and was a favourite medicine of Geoffroy; but, at this time, practitioners have no dependence on it. Within our own remembrance, the syrup, with fragments of leaf gold, was given as a cordial in small pox.

CHE'RMES MINERA'LIS. See ANTIMONIUM.

CHE'RNI'BION, (from *χειρ*, the hand, and *νιπω*, to wash). In Hippocrates it is an URINAL, or rather a WASH-HAND BASIN. Motherby.

CHE'RSA, (from *χερρος*, earth). See FEX.

CHE'RVA. An Arabian name for CATAPUTIA.

CHEVA'LIER. See CALIDRIS BELIONII.

CHEVA'STRE. A double headed roller, applied by its middle below the chin; then running on each side, it is crossed on the top of the head; and passing to the nape of the neck, is there crossed: it next passes under the chin, where crossing, it is carried to the top of the head, until it is all employed. See FASCIA.

CHEZANA'NCE, (from *χεζω*, to go to stool, and *αναγκη*, necessity). It signifies any thing that creates a necessity of going to stool; and in P. Ægineta it is the name of an ointment with which the anus is to be rubbed for this purpose. Ætius gives this name

to a plaster, which was to have the same effect when applied to the navel.

CHI'A. A sweet fig; so named from *Chio* or *Scio*, where they are propagated.

CHI'A TE'RRÄ. EARTH OF CHIOS, now called *Scio*, an island in the Archipelago. It is a grayish earth, brought from that island, formerly used as a sudorific in fevers, but now neglected. Fuller's earth, or pipe clay coloured, and impressed with proper signatures, are the general substitutes.

CHI'ACUM COLLY'RIMUM. In P. Ægineta it is a remedy for disorders of the eyes, of which the dry ingredients were bruised and infused in Armenian wine.

CHI'ADUS. See FURUNCULUS.

CHIA'SMOS. It is the meeting of any two things under the form of a cross, or of the letter *χ*; whence it is named. The adverbs *chiasti* and *chiasticos* mean the same.

CHIA'STOS. The name of a bandage in Oribasius, so called from its resembling the letter *χ*. See FASCIA.

CHIA'STRE, (from the same). A bandage for the temporal artery. It is a double headed roller, about an inch and a half broad, and four ells long. The middle is applied to the side of the head, opposite to that in which the artery is opened; and, when brought round to the part affected, it is crossed upon the compress that is laid on the wound, and then the continuation is over the coronal suture, and under the chin; then crossing on the compress, the course is, as at first, round the head, &c. till the whole roller is taken up. See FASCIA.

CHI'BOU. A spurious species of gum elemi, little known in this country, though common in France.

CHI'BUR. See SULPHUR.

CHICHIA'XOCOTL. See MACAXOCOTLIFERA.

CHI'COS, or CHI'CRES. See BOVINA AFFECTIO.

CHI'EN-DENT. See GRAMEN CANINUM.

CHI'GRES. See HYBOUCOUHU.

CHILCHO'TES. See PIPER INDICUM.

CHI'LI, BALS. DE. This seems to have been an imposition. Salmon speaks, but without any proof, of its being brought from *Chili*. The Barbadoes tar, in which are mixed a few drops of the oil of aniseseed, is usually sold for it.

CHILIPHY'LLON, (from *χίλιας*, a thousand, and *φυλλον*, a leaf). See MILLEFOLIUM.

CHI'LI A'RBOR. See CORT. PERUVIANUS.

CHI'LLI. See PIPER INDICUM.

CHI'LLI INDIE ORIENT. See ZINGIBER.

CHI'LOH, (from *χειλος*, a lip). A person with large prominent lips, either by nature or from disease. The term is applicable to fish, as well as the human species; called also *labeo*.

CHILPELA'GUA, CHI'LTERPIN. See PIPER INDICUM.

CHI'MALATH, or CHIMALA'TL. See CORONA SOLIS.

CHIME'THILON. See PERNIO.

CHIMIA'TER, (from *chimia*, chemistry, and *ιατρος*, a physician). Physicians who make the science of chemistry subservient to the purposes of medicine. Physicians of this description are called also *chemici* and *iatrochimici*.

CHIMO'LEA LA'XA. Paracelsus means, by this

word, the powder which is separated from the flowers of saline ores.

**CHI'NA ORIENTA'LIS.** So called from the country from whence it was brought. *China radix*, *sankioa*, *quaquara*, *smilax aspera Chinensis*, or **CHINA ROOT.** It is the *smilax china*, Lin. Sp. Pl. 1459.

It is an oblong, thick jointed root, full of irregular knobs, of a reddish brown colour outwardly, but inwardly of a pale red. There are two sorts, the East and the West Indian. The first is most esteemed; it is paler and harder than the other, and in China is called *lampatam*.

The plant is climber, with tendrils; and, like the vine, it bears clusters of large berries of a red colour. It is a native of China and Japan.

The root hath but little smell or taste. An inspissated decoction of it yields an unctuous, farinaceous, almost insipid mass. It is supposed to promote perspiration and urine. Prosper Alpinus says, that the Egyptian women use this root to increase their bulk. It first appeared in Europe as an anti-venereal about the year 1535, but now it gives place to sarsaparilla.

This East India china may be distinguished from the other by its yellow-brown colour outwardly; its white, or reddish-white, colour inwardly; by its being in flatish long pieces, full of knots, firm, and smooth when cut.

**CHI'NA OCCIDENTA'LIS.** *China spuria nodosa*, *smilax, pseudo china* Lin. Sp. Pl. 146, *smilax Indica spinosa*. **AMERICAN or WEST INDIAN CHINA.**

This plant is a climber, and bears black berries, grows wild in Virginia and Jamaica, and bears the cold of our climate. The root is brought chiefly from Jamaica in long round pieces, full of knots; whitish without, and reddish within.

In scrofulous disorders it has been preferred to the oriental kind. In other cases it is of similar but inferior virtue.

**CHI'NA SUPPO'SITA.** *Senecio Madraspatanus senecio, pseudo china* Lin. Sp. Pl. 1216, or **BASTARD CHINA.** It grows in Malabar; the root greatly resembles the china root both in appearance and qualities. Lewis's Mat. Med. Raii Hist.

**CHI'NA CHI'NÆ.** See **CORT. PER.**

**CHINE'NSE.** See **AURANTIA SINENSIS.**

**CHINCHI'NA.** See **CORT. PERUV.**

**CHI'OLI.** See **FURUNCULUS.**

**CHI'QUES.** A name which the French give to the worms which are found under the toes of the negroes, and which are destroyed by the oil which flows out of the cashew nut shell.

**CHIRA'GRA,** (from *χειρ*, the hand, and *αγρα*, a seizure). Gout in the hand. See **ARTHRITIS.**

**CHIRO'NES,** (from *χειρ*, the hand). See **BOVINA AFFECTIO.**

**CHIRO'NIA,** (from *χειρ*, the hand). See **BRYONIA NIGRA.** It is also a name for the centaur. See **CENTAURIUM.**

**CHIRO'NIUM.** A malignant ulcer, difficult to heal, with a hard, callous, and tumid margin; so called from Chiron the centaur, who is said to be the first who cured it. It is also called *telephium*.

**CHIRONO'MIA.** See **CHEIRONOMIA.**

**CHIROTHE'CA,** and **PODOTHE'CA,** (from *χειρ*, manus, and *πες*, pes, or *τιθημι*, pono, to put). In the preparation of anatomical subjects, they are a glove and

a shoe of the scarf skin, with the nails adhering. They are separated with very little trouble after the cuticula loosens from the parts below by putrefaction; and this method is better than that of separating it by means of boiling water.

**CHIRUR'GIA,** (from *χειρ*, a hand, and *εργον*, work, manual operation). **SURGERY,** or that part of medicine which consists of manual operations.

It was our intention to have comprised under the article of medicine a general history of that science, as well as of anatomy and surgery; and we consequently omitted in its proper place the particular history of the former. On contemplating the subject more nearly, we find that it will be too much broken by subjects which, though generally connected, yet branch into distant ramifications. As anatomy is perhaps more intimately connected with surgery than with medicine, we have therefore preferred giving a short sketch of the origin and progress of each in the present article.

Anatomy and surgery are the sciences of a rude warlike race; for however simplicity of diet and constant labour may preserve health, yet in this ruder state of society, wounds and bruises must have been frequent. If the nation were ferocious and often engaged in combat, the knowledge of the former would be more generally disseminated, and the practice of the latter more necessary. Thus each science was very early cultivated; and in Homer no slight knowledge of anatomy is displayed. The Egyptians, whom we generally compliment with the earliest advances in every science, often with little reason, were probably acquainted with the structure of the human body from their practice of embalming, and it is said that their kings left treatises on anatomy. If what Prosper Alpinus has described as their later practice was traditionally conveyed from the early ages, they had also made a considerable progress in surgery; but we have reason to believe that the greater part was taught them by the Greeks, as we know the practice of bleeding to have been. The Egyptians had their *Æsculapius*; whom the Greeks, in their usual method of appropriating every distinguished personage to their own nation, have transferred to Greece. After *Æsculapius*, we find the names of Chiron the centaur; Machaon and Podalirius, two sons of *Æsculapius*, mentioned by Homer; Thales, Empedocles, Pythagoras, Heraclitus, and Democritus. The small circle of the philosophy of those days would not be greatly crowded by the admission of anatomy and surgery; and we know that some of these philosophers assiduously cultivated the former study. We have the authority of Stephen of Byzantium for Podalirius having practised phlebotomy.

We can only judge of the ancient state of anatomy and surgery from the works of *Hippocrates*. He seems to have collected with great diligence all the observations of his predecessors, but his anatomy was general, and somewhat superficial. He is accused of dissecting brutes, and describing the organs of apes as those of the human race. Indeed this seems to have been true, if all, even the undisputed, writings attributed to him be really genuine. Yet many of these are evidently interpolated; and very few indeed have reached us without some ground of suspicion. His surgery deserves a better character. His remarks on ulcers and wounds, even at this time, merit attention; but his

operations were few. He opened abscesses, penetrated the thorax to discharge any effused fluid, and the abdomen for the same purpose: the head he perforated with the trepan. His chief surgical operation was the actual cautery, which he recommends in a variety of diseases, and which modern delicacy or timidity has banished with too little discrimination.

Various were the followers of Hippocrates, of whom we have received little more than the names, till the time of *Diocles*, at the distance of one hundred and thirty years from his era, and about three hundred and eighty years before the birth of Christ. He invented an instrument for extracting the point of an arrow sticking in a wound, and some bandages which, like the instrument, bore his name. The last of the Asclepiadean race was *Praxagoras*. He is recorded in desperate cases of ileus to have opened the abdomen and intestines in order to evacuate the fæces, and then to have sewed up the wounds in each.

The improvements in anatomy during this long period were probably few, at least scarcely any additional knowledge in this branch has been preserved. The era of the *Alexandrian school* has not been accurately ascertained; but its distinguished professors, *Herophilus* and *Erasistratus*, were minute anatomists, and many parts of the human body still preserve their names as discoverers. We have received their improvements only in the works of Galen, at the distance of three hundred and fifty years. They both practised surgery; and Erasistratus, who was a century earlier than Herophilus, opened the cavity of the abdomen in cases of diseased liver, to apply his remedies to the part itself. *Asclepiades* of Bithynia was the cotemporary of Erasistratus, and, as appears from Plutarch, an experienced surgeon; but his chief reputation arises from the revolution he occasioned in the practice of medicine, which is not our present object. *Cassius*, perhaps a scholar of Asclepiades, at least a cotemporary of his scholars, was apparently an able anatomist and a skilful surgeon; and Aretæus, who lived near the time of our Saviour, was more distinguished for his medical abilities, than for anatomical or chirurgical knowledge.

Whatever was the era of *Celsus*, he is certainly the first author after the birth of Christ, who merits our regard. His style has been the admiration of ages, and in his collections he appears to have been diligent and attentive. It has been doubted whether he himself practised. From some parts of his works it is evident that he did, but not frequently, or probably in important cases. His seventh and eighth books are wholly chirurgical, but in these he treats chiefly of operations; for to these he seems to confine the office of the surgeon.

*Celsus* mentions the operation of lithotomy, but this is not the first time of the subject occurring. We delayed, however, noticing it till we could bring the whole together. It appears from Hippocrates, that the extraction of the stone was practised in his time, but confined to particular operators, and he forbids its being attempted except by them. Of their methods or success we have no particular information; and we have only an obscure ray from the Alexandrian school, of a surgeon who attempted to break the stone in the bladder when it was too large to be extracted entire. In *Celsus* the operation described is that with the lesser apparatus.

One hundred and fifty years elapsed before any other author worthy of particular attention offers himself to our notice, and we then meet with the famous *Claudius Galenus* of Pergamus, whose undisputed sway over all the realms of medicine continued for more than twelve hundred years. Galen was a laborious collector, and a diligent dissector: his anatomical knowledge was extensive, and in his work are preserved all that former observers knew. In surgery he possesses little originality, and chiefly comments on the writings of Hippocrates. From this period, the history of anatomy presents for ages a dreary, unproductive desert. Little was added by the Galenists, who feared to step beyond their master; and the Arabians, who preserved the spark of science when it was nearly extinguished in the West, thought themselves polluted by touching a dead body. Surgery, however, was cultivated with care. It has been in all ages, in every revolution of society and science, a necessary acquisition.

Nearly two hundred years after Galen, *Oribasius* flourished, who explained and illustrated very satisfactorily many parts of the Pergamenian's doctrine. His chirurgical chapters are full and instructive, but he possesses little originality. He has been stigmatised as a compiler, and in reality is little more. *Ætius* of Amida, followed him, probably about the distance of one hundred years, and seems to be a superior author in many respects, though it is not easy to appreciate his chirurgical merit from the unconnected form of his observations. His method of puncturing the legs in anasarca, and of relieving inveterate asthma by numerous cauteries, merits particular attention. He was acquainted with the use of setons; and the wounds inflicted by the bites of mad animals should, in his opinion, be kept open sixty days. In *Ætius* are some fragments of *Leonidas*, a surgeon of the school of Alexandria. The only novelty we perceive in these, is the treatment of the Guinea worm, the dracunculus.

Paulus of *Ægina*, whom Dr. Friend places in the seventh century, has been styled the ape of Galen, as his works are supposed to be servilely copied from that author. We do not indeed perceive so many originalities in Paulus as some of his admirers seem to have discovered; but he is by no means a compiler only. He was apparently a judicious practitioner; and in his works the whole of the ancient surgery is detailed more copiously and accurately than in those of any other author. His account of aneurisms is new. He describes (almost) the lateral incision in lithotomy, and apparently first mentions the fracture of the patella. If not the first author who recommends bronchotomy, he is certainly the first who distinguishes with precision the circumstances in which it is successful.

The chief Arabian surgeons were *Rhazes*, *Avicenna*, *Avenzoar*, and *Albucasis*. It would fill but a few lines were we to add all the improvements of the three former. The description of an abscess in the mediastinum by Avenzoar deserves indeed to be mentioned, with his proposal of trepanning the sternum, which some modern authors have practised with success; but the complaint is by no means so accurately distinguished as to enable us often to follow the example. Albucasis has given us a complete system of surgery copied professedly from Hippocrates and Galen, sometimes apparently from Paulus of *Ægina*; but many observations and improve-

ments of his own are added. We may mention one, as it has been lately the subject of some dispute, that is, tying the artery to stop hæmorrhages; an improvement usually attributed to Ambrose Parey.

At the restoration of learning, authors of credit were soon numerous, and surgery improved rapidly. Anatomy for a time lingered in its former imperfect state. When a surgeon appears only in a century, he becomes a distinguished figure on the canvas: the crowd that now hastily follow each other must be considered more cursorily. Indeed, the greater number who first distinguished this era were merely copyists of Albucasis; nor have Saliceto or Lanfranc sufficient originality to induce us to rest on them for a moment. *Guido de Cauliaco* was the first who had any pretensions to originality; though these rather consist in judicious remarks on his predecessors, than any improvement peculiarly his own. In cataracts he depressed the lens.

At this time surgery in England was at a low ebb. Gilbert was very imperfectly instructed in his art; John of Gaddesden was a quack; and of John Arderne's works we cannot judge, as they have not been printed, if we except the *Treatise on the Fistula in Ano*, translated by Read. He is spoken of, however, with respect by Friend.

The appearance of the venereal disease in the sixteenth century turned the attention of surgeons to one object, though they were not wholly inattentive to the science in general. *Vigo's Surgery* is a work of considerable merit; and he explains, particularly, the mode of tying the arteries when cut. Some authors think him the first surgeon who used mercury in the venereal disease, the credit of which is usually given to *Carpi*, who undoubtedly first employed mercurial frictions. *Carpi's* only other chirurgical work was on the fracture of the skull. *Marianus Sanctus*, who wrote on a particular mode of cutting for the stone, which he attributes to John de Romanis, was an author of this period. *Antonius Ferrus*, and *B. Maggius* of Bononia, published on gun shot wounds; *Vidus Vidius* and *J. Andreas* on surgery in general; and *Taliacotius* on supplemental noses, about this period.

*Ambrose Parey* claims a greater share of attention. His works may be even at this time read with considerable profit, as he treats of every branch of the science with considerable judgment and precision. He was the first who condemned the practice of dressing gun shot wounds with hot irritating oils; and to him the checking hæmorrhages by ligatures on the arteries has been attributed. He possesses such a variety of merit, that he may resign his claim to this discovery without any injury to his fair fame. *Franco* is a French surgeon, who treats with singular precision on *herniæ*, and mentions the use of the seton in hydrocele. He was the inventor of the high operation for the stone, urged by necessity, as it was too large to be extracted by De Romanis' plan. *Paracelsus* was also a surgeon of this era, but of no credit; *Forestus* deserves a higher character, and his works even at this time are valuable.

It may appear that we have forgotten the history of anatomy; but in the whole of this period no anatomist of character has appeared to claim our attention. We now, however, approach a period when the science was assiduously cultivated; and we have passed over Fallo-

pius and Vesalius, who, though distinguished as surgeons, yet merit more particular notice as anatomists.

Anatomy, in the sixteenth century, dawned with *Sylvius*; but, servilely attached to Galen, he did little more than explain that author's works. *Vesalius* was his pupil; and, ardent in the study of anatomy, he soon discovered many errors in the descriptions of Galen, and clearly showed that they were taken from the dissections of brutes, particularly apes. The clamour which this accusation excited was inconceivable: even denying the infallibility of the pope would have been, among the anatomists of that era, a comparatively venial crime. His master, *Sylvius*, continued for ever, on this account, his irreconcilable enemy. Science, however, gained by the contest; for, if *Vesalius* and Galen were at issue, the contest must be decided by actual observation. The result was, on the whole, favourable to *Vesalius*; but unfortunately he was, in some instances, detected in the same disingenuity of which he accused Galen. The anatomy of *Vesalius*, however, continued to be for ages a work of peculiar interest and value. The early editions are illustrated with wooden cuts, it is said, from the drawings of Titian. They are, indeed, executed in a style truly masterly; but the great painters of that era, Raphael, Titian, and Leonardo de Vinci, were excellent anatomists, so far as the structure of the parts influenced the external form.

*Fallopius* was also an author of this century, though later than *Vesalius*. His *Observationes Anatomicae* were published in 1561, and his discoveries were numerous. The tubes which convey the ovum to the uterus still bear his name. *Eustachius* lived somewhat later. His tables, which he himself engraved, were found without any explanations, and published by *Lancisi*, in 1714, with some short and imperfect elucidations. They were republished by *Albinus*, with a copious commentary; and even at this time are, with a few exceptions, very correct and satisfactory. *Eustachius* was, however, no man's friend, and a violent enemy of *Vesalius*. His anatomical discoveries were numerous and important. Though able and scientific, yet, from a spirit of opposition, he often defended Galen; and thought that he had gained a victory, when he proved that some of the parts were not described from apes, as *Vesalius* supposed, though he admitted that they were copied from brutes. He intended that his plates should be explained by a geometrical gnomon, to avoid the obscurity which letters of reference would occasion; but his plan is lost.

The other anatomists of this century are not of sufficient importance to detain us long. Yet we ought not to omit, in the Italian school, the only one to which we are indebted for anatomical knowledge, *Mercurialis*, who merits more particular attention as a practical physician, but who was also an expert anatomist; *Casalfinus*, who clearly described the lesser circulation through the lungs; *Varolius*, whose name is preserved in a distinguished part of the brain; *Schenckius*, whose collections furnish us with so many singular, often incredible narratives; *Caspar Bauhine*, the botanist; *Laurenti*; *Castellus*, our predecessor in lexicography; *Fabricius, ab Aquapendente*; *Hildanus*; *Kepler*, the astronomer; *Riolan*: the elder *Bartholinæ*, *C. Hoffman*, *Sennertus*, *Spigelius*, and *Severinus*.

We have, contrary to our intention, stepped beyond the limits of the sixteenth century, to extend our historical sketch to the period of Harvey. The early part of the seventeenth century was the era of discoveries, *Asellus* ascertained the existence of the lacteals, *Harvey* of the circulation of the blood; while he, at the same time, established many important facts respecting the generation of animals, establishing, on the firmest foundation, that universal axiom, *omne ex ovo*. The discovery of the circulation has immortalized the name of Harvey; yet we must add, that the facts already established left little more to be done than to collect and compare them; nor have we any hesitation in remarking, that the greatest discoveries, that of Newton, respecting the universal influence of gravitation, and of a new world by Columbus, were in the same way prepared, so as to require only "patient thinking," attentive examination, and a comparison of facts already known. *Servetus* alluded to the lesser circulation through the lungs; *Cæsalpinus* described it more distinctly, and proved it by the structure and situation of the valves. May not then all the blood in the body circulate? The question was ready and obvious; and the chief merit of Harvey and of Newton was that of bringing a simple suggestion to such a rigorous examination, as incontestably to demonstrate its truth. It has been triumphantly asked, What have we gained by either? Were it no more, we have divested superstition of its terrors, and quackery of its vain pretensions; but the discovery of Harvey imperceptibly mixes in every step, either of speculation or practice: the result is now so interwoven with every thought, that its influence is not perceived.

In the seventeenth century the names crowd on us in such a multitude, that even the enumeration is almost impracticable. Among anatomists and surgeons, for we can now scarcely distinguish them, we find *Sylvius de la Boe*, *Veslingius*, *Horstius*; the younger *Bartholine*, an author of peculiar industry, of great abilities as an anatomist, and a strenuous defender of the newly discovered absorbent system; *Schneider*, the discoverer of the extent of the Schneiderian membrane and author of an extensive work on catarrhs; *Ballonius*; *Van Helmont*; *Vanderlinden*, the very accurate editor of Hippocrates; our own *Charleton* and *Higmore*; *Pecquet*, the discoverer of the receptacle of the chyle; *Wallis*, who gave us the first rudiments of the method of teaching the deaf and dumb to speak; *Glisson*, the author of the *Anatomia Hepatis*; *Bohnius*, to whom we are indebted for a work on the eye, and an excellent treatise, *De Renunciatione Vulnerum*; *Schultetus*, who gave us a most instructive work on surgical instruments, and has preserved the form of many, which would have been otherwise forgotten; *Wharton*, author of the *Adenographia*; *Wepfer*, *Wedelius*, *Willis*, of Oxford, whose talents, as an anatomist and physician, are not adequately appreciated at this time; *Malpighi*, a naturalist and anatomist of the highest rank; *Steno Bellini*, a mechanical physiologist of considerable ability; *Borelli*, the disciple of Bellini; *Drelincourt*, the anatomical preceptor of Boerhaave; *Redi*, *De Graff*, *Ruych*, *Svammerdam*, *Lower*, *Etmuller*, *Mauriceau*, *Muralto*, *Lister*, *Ray*, *Pechlin*, *Diemerbroeck*, *Lewenhoeck*, *Duverney*, *Tyson*, *Grew*, *Nuck*; *Bidloo*, the author of some excellent anatomical plates, which Cowper has been accused of republishing, without any acknow-

ledgment, and with little alteration; *Vicussens*, author of the *Neurographia Universalis*; *Vanderwielt*; and our own *Wiseman*, though last, not least.

The extent of this catalogue, though numerous authors of credit are omitted, prevents us from following at length the anatomists and surgeons of the last century. To attempt it would be a labour of immense extent, disproportioned to the work; and it would be in a great measure useless, since they are generally known. In the early part of the last century *Dr. Douglass* taught anatomy with credit; and to him we are indebted for *Dr. William Hunter*, and, more remotely, for his brother, *J. Hunter*. In Scotland, the first *Monro* was an anatomist and surgeon of unrivalled excellence. In Germany, *Haller* merits peculiar and distinguished commendations; while, in both countries, the second *Monro*, *Hewson*, and *Meckel*, perfected the discovery of the third distinct system of vessels, the lymphatic, which *Mascagni* of Italy has delineated with singular elegance. Italy can also boast of the very able anatomists, *Morgagni* and *Valsalva*.

In surgery, *Cheselden*, *Sharp*, *Pott*, and many others, have been equally an ornament to their country and to the science they professed; nor have their successors been less distinguished: but of living surgeons it is not perhaps proper to speak, since it is so difficult to speak without offence. In France, *Petit*, *Mery*, *Le Dran*, *Le Cat*, *Daviel*, and *Peyronie*, have greatly extended their art; and in Germany *Heister* has given the best general system of surgery, which appeared before that of Mr. Bell.

Here, then, we must close the history of surgery, and proceed to the other branches of this article. The object of surgery is apparently every external complaint not owing to an internal cause, and every disease in which an operation is required. Of the first class are, wounds, tumours, inflammations, and organic complaints. The latter comprehends a great variety of internal complaints, which are partly the object of the physician, and, in part, of the surgeon. These are, diseases of the brain from compression; fractures of the cranium; polypi of the nose; accumulations of cerumen in the ears; scirrhus tonsils; obstruction of the larynx from inflammation; accumulations in the chest, either of air, water, or purulent matter; herniæ of every kind; abscesses of the liver, or other viscera, pointing outwards; calculus in the kidneys or bladder; suppression of urine, or fæces; fractures; dislocations; diseased joints, &c. Yet the surgeon should reflect, that he will always merit greater praise from curing without an operation, than by an operation performed with the greatest dexterity. Unfortunately, many surgeons suppose that the operation is their chief business; that, by it, their character obtains a degree of splendour, which the best and most successful plan of cure would not otherwise claim. Let the young surgeon disregard this delusive splendour, which will entice him often to his patient's injury. On the other hand, let him not too long delay an operation that may be necessary, or protract to the moment of exhausted strength what requires some efforts of the constitution to bear or contend with. Each fault is too common; and it has been a great object, in our separate articles, to give such rules as may correct either tendency.

When an operation of importance is necessary, it becomes the surgeon's duty to state to the friends the real probability of success, without exaggeration on one side, or too doubtful hesitation on the other. The whole truth, as it appears to him, should be faithfully and explicitly detailed. If, from a fair view of the arguments, the operation be decided on, the patient's consent should also be gained; yet, at this time, every encouraging circumstance should be displayed, and every doubt suppressed, or, at least, suggested with caution. The pain, the hazard of an operation, will strongly bias the mind, and give every doubt a disproportioned force; nor is the moment of pain and distress such as will enable the patient to examine contending arguments with the requisite discrimination and impartiality.

When an operation is performed, it was formerly fashionable to display the dexterity of the operator by a rapid execution. Neatness, accuracy, and minute precision, are now studied. We do not think the change advantageous to the patient. If the operation is not so much hurried as to occasion error, it cannot be performed too soon; and nothing is gained by detaining the patient on the table three times the necessary time, because the knife shall be carried as near as possible to an artery without wounding it, or because the smallest particle of muscular flesh shall not be included in a ligature. We have seen an operation performed so slowly, as if the operator thought his success was only obtained by a dilatory caution. After the operation, the application of the bandage is of the greatest consequence; and, as the ease of the patient is much connected with the neatness with which it is applied, the utmost attention should be paid to this part of the process.

The profession of a surgeon is of the highest importance to society, and it requires a greater combination of talents than any other within the circle of scientific attainments. The object is certainly more nearly within the reach of the senses. The surgeon has not, like the physician, to contend often with a form or phantasm. Yet he cannot pursue a disease in all its bearings, in all its consequences, without the most careful discrimination of causes and effects, without an attentive examination of the influence of an injury on the most distant parts. With these powers, he must have a command of hand to enable him to direct his knife with the utmost nicety and precision; a mind unruffled by any accidental unexpected occurrence; and a readiness of resource to supply the assistance necessary in any emergency. His senses must possess peculiar acuteness, particularly the feeling, which is often more important than even the sight. His hand must not tremble; his mind be unassailed by fear, by apprehension, or doubt, when the necessary operation has been once decided on. It is observed by Celsus, that a surgeon should be able to use either hand; but, by attaining this power, the right might lose a portion of its dexterity; and, though the left may occasionally in the less nicer parts assist the right, yet it should not be wholly trusted. It is said that the surgeon should be young, at least *so young* as not to have the necessary powers impaired, and of sufficient age to have attained the requisite experience. Undoubtedly, by age the faculties are blunted: doubt and hesitation take the place of a proper confidence and a manly firmness; the hand is less steady; the feelings

less acute. The age cannot be fixed, since the powers of each individual differ at a given time of life. We have known many surgeons of character and abilities who have limited their professional career at the age of sixty. But this decision, formed with the candour and ingenuousness of youth, has been forgotten when they reached the limit. It shows, however, their opinion; which were we to controvert, it would be by fixing a less extended period. But this we would only confine to capital operations; long after sixty a surgeon of abilities may be eminently useful in consultations.

A quality very necessary for a surgeon is, a knowledge of mechanics, and a readiness in adapting little mechanical contrivances to the exigencies of the moment. It is inconceivable how much pain and distress are alleviated by such ingenuity; how the cure is often accelerated, or the spirits supported.

Humanity is, above all, required to complete this first of characters, a good surgeon. In general, surgeons are proverbially cruel, and they often must be so to fulfil their duty. Yet there is a tenderness of manner that makes even cruelty tolerable; in comparison, amiable: and, though the surgeon ought not to feel, he should as much as possible lessen, the patient's pain, and appear to be sensible of his sufferings. A softness of manner, a gentleness of voice, and even a delicacy of form, are not without their effect; and whatever can alleviate distress, though trifling in the general scale, should not be neglected. To the one the patient looks with horror as the butcher; to the other as the ministering angel, bringing balm on his wings to heal and to save. We have employed these few lines for the sake of our younger brethren. May they not be without their effect!

We thought that we had completed our task, when we were reminded that the recommendation of the study of anatomy was omitted; but this first, this most important, qualification, can never be neglected by him who aims at the character of an accomplished surgeon. It should be his study day and night: the human body should be the work, *nocturna versari manu, versari diurna*. The knife should be constantly in his hand to attain a readiness in using it in every direction; to vary the direction in a moment at every angle of obliquity; to stop; to proceed; to alter the velocity with the readiness which governs the movements of the best managed horse, or, to employ a more delicate metaphor, the finger of the most experienced musician. But this must be a part of his education; nor should he claim the confidence of the public till all these qualities are attained.

The study of the practice of physic may not be considered as essential to a surgeon: yet, as the complaints which are occasionally arranged under each head vary in their minute shades and press on each other, it is highly necessary that medicine should make a part of his education. It has, however, often happened, that a knowledge of the one has led to a presumption that it has equally inspired an acquaintance with the other; and each has intruded in a department not his own, without a sufficient qualification for the due exercise of it. A surgeon should, we think, possess a sufficient knowledge of medicine, to regulate the general treatment of the diseases within his own limits. Beyond them he should not pass, without having paid that

attention to the other science, which, had he cultivated with care his own, he would have little opportunity of attaining. The physician should be equally careful of interfering; yet, in a comprehensive view, surgery becomes a part of his profession. A man of science grasps particulars in an outline; and as the operative part is beyond his limits, there is nothing to prevent his acquisition of so much of surgery as will enable him to assist, sometimes to direct, the less experienced practitioner.

One other subject only remains; a subject which we could not have supposed would ever have occurred in a questionable form, viz. whether surgery is improved by the labour of the moderns, and raised above its former state. Let humanity decide, and the cause will be soon determined; but we will not harrow up the soul by the repetition of former cruelties. The question will recur in another shape: Is the modern surgeon more successful than his predecessors? The reply is easy. Do we still pour hot irritating oils on gun shot wounds? Are not wounds quickly cured by the adhesive inflammation, which required months by the former methods of supuration? Is not the stump healed, by means of the flap, in a few weeks? Does the wound, from which the cancerous mamma has been extirpated, require any thing more than superficial dressings? To pursue the subject minutely, would be to waste the reader's time and exhaust his patience. Let us select an instance or two. In herniæ the operation was precarious and ill understood: it was consequently but seldom attempted. The modes of reduction were little known, and the trusses so imperfectly calculated for the purpose, that, when reduced, the intestine was seldom retained. We have selected this instance; because we can appeal to facts, viz. the numerous advertisements, even in the beginning of the last century, of rupture cures. The greater number we now know can be reduced and retained with little difficulty; and of those cases which require the operation, nearly one half escape. If the operation were not too long delayed, the proportion of successful cases would be greater.

In lithotomy, confined for ages to one set of practitioners, the means were limited and inadequate. The method described by Celsus was, from its nature, confined to the age of from nine to fourteen. How many years previous, how very many subsequent, to that age, must have been spent in unsufferable agonies! What then was the attempt? First, with the greater apparatus; and, secondly, in the higher way. Even when it succeeded, an incontinence of urine frequently followed each; and in the greater number it failed. When Frere Jacques pointed out the lateral operation, how crude and imperfect were his first ideas! The grooved staff and the cutting gorget were the improvements of very late years. But, previous even to the latter, Cheselden had so far simplified the operation, that many surgeons have professed being able to perform it in the dark. Indeed, it is one of many operations which depends on the nicety of the feelings rather than the sight.

The systems of surgery in our hands are few. The practice of the ancients may be found most eloquently described in Celsus; but at greater length, and often more satisfactorily, in Albucasis, with numerous improvements, which he claims as his own. It was published with Guido's Surgery, in folio, at Venice, 1500;

again in 1506 and 1520; but the best edition is that of Strasburgh, in 1532, or that at Basil, 1541.

Heister connects, very properly, the ancients with the moderns; and, among the latter, Mr. Benjamin Bell almost stands alone; for Mr. Latta's system is less complete, and Mr. J. Bell's a very inferior work. Mr. B. Bell is, however, too minute and tedious; and so disproportionate is his share of attention, that bleeding occupies nearly as many pages as lithotomy. The chief inconvenience, besides unreasonably enlarging the work, is, that the young surgeon may attempt the more important operation with the same confidence that he has often successfully performed the less. From the character of Mr. Blair, we have reason to expect, with some impatience, his promised system.

To enumerate the other independent works is unnecessary, as they will occur under each head, and they are so numerous as to form an extensive catalogue.

CHIRURGO'RUM SAPIENTIA. See SOPHIA

CHIRUR'GUS. See CHEIRIATER.

CHIST. See SEXTARIUS.

CHITON. (Greek.) See MEMBRANA.

CHI'UM VINUM. CHIAN WINE. A wine of the island now called *Scio*. Dioscorides says it is less disposed to intoxicate than any other sort.

CHIVES. See STAMEN.

CHIVETS. The small parts at the roots of plants by which they are propagated. Miller's Dict.

CHIVIQUELE'NGA. See CATAPUTIA MINOR.

CHILIA'SMA, (from *χλιαiva*, to make warm.) See FOTUS.

CHILMIA. See CADMIA.

CHLO'RA. GREEN. See CHLOROS.

CHLORA'SMA, and CHLOROS, (from *χλωρος*). A palish green colour, shining with a sort of splendour, and inclining to watery: it is applied to leguminous plants before they are dry or come to perfection.

CHLORO'SIS, (from *chloros*, *χλωρος*, green). The GREEN SICKNESS, called also *febris alba*, the VIRGIN'S DISEASE, *amatoria febris*, and *icterus albus*. Though Hippocrates does not seem to have known these names of this disorder, yet in the 34th and 35th paragraphs of his book *De Internis Affectionibus*, he describes it fully; and when it happens to girls, he speaks of it in his book *De Virginum Morbis*.

Most authors treat it as a species of eachexy, and indeed it is only distinguished from other species by its cause. (See CAEHEXIA.) Dr. Cullen considers it as a symptom of amenorrhœa.—A vitiated appetite, a strong desire of eating unalimentary, often absorbent, substances, are constant attendants on this disorder; and, if married women become *chlorotic*, their children are weakly, should they have any. THE COMMON SYMPTOMS, *when from difficult menstruation*, are a paleness in the lips, a livid colour about the eye lids, indolence, coldness, particularly in the feet, loss of appetite, nausea, vomiting, disturbed sleep, a languid pulse, limpid urine, which in time becomes turbid, a tremor, if exercise is brisk, or if the patient ascends a hill, frequent palpitation of the heart, swelled feet, heart burn, intermitting headaches, and fainting. See MENSES DEFICIENTES.

CHNU'S, *χνος*, FINE SOFT WOOL; but sometimes CHAFF or BRAN; (from *χνεωω*, to grind, or rasp.) Sound, or wind.

CHO'A. See CHU.

CHO'ACON. The name of a black plaster, mentioned by Celsus, made of a spuma argenti boiled in oil, added to a proper quantity of resin.

CHO'ANOS, *Χοανη*, A FUNNEL, (from *χυνω*, to pour). See INFUNDIBULUM. A funnel, or furnace for melting metals.

CHOA'VA. See COFFEA.

CHOCOLA'TA. This is said by Dr. Alston to be compounded of two Indian words, (from *choco*, sound, and *atte*, water; because of the noise made in its preparation). See CACAO.

CHÆ'NICIS. The TREPAN; so called by Galen and P. Aegineta, from *χοινίξ*, the nave of a wheel; (from *χυνω*, to tear, or vellicate). See TREPANUM.

CHÆ'RADES, (from *χοίρος*, a swine). Strumous swellings, of a malignant quality, painful to the touch, and exasperated by medicines. See SCROFULA.

CHÆRADOLE'THRON, (from *χοίρος*, a swine, and *ολεθρος*, destruction; so called from being dangerous if eaten by hogs). See BARDANA MINOR.

CHO'IRAS, (from *χοίρος*, a hog). See SCROFULA.

CHO'LADES, (from *χολη*, bile). See INTESTINA.

CHO'LAGO, (from the same). The small intestines which contain bile. See ILIUM.

CHOLAGO'GA, CHOLAGOGUES, also *colegon*, (from *χολη*, bile, and *αγω*, to drive out or evacuate). By *cholagogues* the ancients meant only such purging medicines as expelled the bilious fæces. We retain the word for such purgatives as are found most useful when bile offends, or are of service when the liver is diseased. Of this kind are rhubarb and calomel, which are supposed to increase the bilious discharge more powerfully than any other medicine. Aloes and taraxacum have been considered as useful in occasioning the bile to pass freely into the intestines, though with little reason. See CATHARTICA.

CHO'LAS. See ILIUM.

CHO'LE, (from *χολη*, bile). See BILIS.

CHOLE'DOCHUS, (from *χολη*, bile, and *δεχομαι*, to receive). It is a common name for the gall bladder, the biliary ducts, and the common gall duct, which communicates with the duodenum, called

CHOLE'DOCHUS DU'CTUS. It seems to be a continuation of the ductus cysticus; for it is often observed, that the ductus hepaticus runs, for some space, within the side of the ductus cysticus, before it opens into its cavity: at the opening of the hepatic duct into the cystic, there is a small loose membrane to hinder the bile from regurgitating.

CHOLE'GON. See CHOLAGOGA.

CHO'LERA MO'RBUS. Cælius Aurelianus says, the name is derived from *χολη*, bile, and *ρεω*, fluo. It is called also *diarrhæa cholericæ*, *felliflua passio*, and by some of the ancients, *holera*.

Hippocrates divides this disorder into the moist and dry; and there is a kind of cholera morbus which frequently happens to children from dentition. Dr. Cullen names it *cholera*, and defines it a frequent vomiting and purging of a bilious humour, attended with anxiety, gripings, and spasms of the legs. He ranks it in the class *neuroses*, and order *spasmi*. He observes two species: 1. *Cholera spontanea*, which happens in hot seasons, and without any manifest cause: 2. *Cholera acci-*

*dentalis*, which occurs from too acrid materials taken into the stomach.

The intermittent, inflammatory, arthritic, and vermiform cholera, are considered truly symptomatic. The true species is most frequent in autumn, and happens chiefly to young persons, and its seat seems to be the whole volume of the intestines, but more particularly the duodenum and biliary ducts, as appears by the vomiting and stools, which are bilious.

The cholera and bilious diarrhœa are incident to the bilious and dry constitutions; for those of a phlegmatic and sanguine habit are more frequently liable to a different discharge. Those who are subject to a scorbutic acrimony, or those of a passionate temper, are the commonly reputed victims of the disease. In sultry weather it is most frequent: hence it is said by Bontius and Thevenot to be endemic in India, Muritania, Arabia, and America.

The true cholera attacks often suddenly: sickness, pain, flatulency, and distention of the belly, are first perceived, and are soon followed by frequent vomiting and purging of bilious matter; the vomiting and purging come on together, and continue very frequent, with violent pain. The matters voided are at first the remains of the food; afterwards bilious fluids, more or less mixed with frothy mucus, of a yellow, green, and, at last often a black colour; sometimes bloody, like the washings of flesh, extremely acrid, and almost corrosive. The pulse is frequent, and sometimes small or unequal; heat, thirst, and anxiety, now attend; cold sweats presently appear, and spasmodic contractions affect the extremities. In greater degrees of this disorder, the muscles of the belly, and, indeed, the whole body, are seized with spasms: ineffectual strainings to vomit, with almost continual urging to stool, usher in an hicough, lividness of the nails, convulsive contractions of the legs and arms, and death sometimes within twenty-four hours.

In the dry species, there is a considerable distention of the stomach and intestines by wind, which is plentifully discharged both upward and downward with extreme anxiety, but without either vomiting or purging.

The remote causes are various; as acrid poison taken into the stomach, active emetics or purgatives, acrid, fermenting, or putrescent, drinks or diet, and violent passions.

The immediate cause is the irritation of the nervous coat of the stomach and intestines, which is communicated to the biliary system, occasioning the violent pain and the discharge.

Hoffman says, that the dangerous vomiting and purging which infants are thrown into from the vehement anger of the nurse, and those which follow the exhibition of arsenic, some other poisons, and the virulent cathartics and emetics, seem to be no other than the true cholera.

The dry cholera proceeds from a collection of acrid and flatulent humours in the stomach, by which the adjacent nervous parts are irritated and distended.

The cholera morbus must be distinguished from a bilious looseness, a dysentery, and the dry cholera. It is distinguished from the first by its rapid attack, its violence, and short duration; from dysentery, by the absence of the violent forcing pains, and the ineffectual

mucous evacuations; and from the dry cholera, by the nature of the discharge.

It is often fatal in hot climates, though seldom in temperate ones. The more corrosive the matter discharged, the more intense the heat and thirst, the greater is the danger. Hippocrates observes, that if black blood and black bile are voided together, death is certainly at hand; and an exorbitant discharge of a green fluid, both upward and downward, fainting, hiccough, convulsions, coldness of the extremities, cold sweats, a small intermitting pulse, and the continuance of the other symptoms, after the looseness and vomiting cease, are mortal signs: yet, in this country, all these may concur from a common bilious vomiting, without danger, if they do not continue long after the discharges cease. Danger is extreme, if what is vomited smells like the internal excrements. If the vomiting ceases, sleep succeeds, and the patient seems relieved, there are hopes; if the disease continues more than seven days, it is seldom dangerous; but the best sign is a free discharge of flatus downward.

The general indications of cure are :

1st, To correct the acrid matter, and; if necessary, to expel it by art.

2d, To check the violent commotions.

3d, To strengthen the weakened organs.

Cholera, strictly speaking, arises from a discharge of superabundant acrid bile. It is the disease of hot climates, and of intemperately warm weather; but similar symptoms are sometimes produced by poisons, by anger, or fermenting food and drinks. In all these cases mild diluting liquors may be given, and the management as in real cholera adopted. The only difference in practice arises from the advantages of giving opiates sometimes earlier and more freely.

In the true cholera, Aretæus long since commended frequent small draughts of tepid water, to evacuate the present contents of the stomach; and when bilious discharges, loathing, and restlessness, afterwards come on, a quarter of a pint of cold water, to check the purging, to cool the ardent heat of the stomach, and to abate the thirst, may be given: this he advises to be repeated as often as the patient throws up what he drinks: and if fainting, with other symptoms of weakness, appear, a little wine may, he thinks, be added to each draught of water.

Many since Aretæus have extolled cold water, and the more so, as the climate, season, and constitution of the patient are warm; for it cools, blunts acrimony, and restores the tone of the parts. In this country it may be given safely, if large draughts at a time are avoided; but toast and water is perhaps safer.

Sydenham commends a similar practice. He orders, if called in at an early period of the disease, a chicken to be boiled for a short time in three gallons of water; of this the patient is to drink freely, and a part is to be injected as a clyster, until the whole is consumed: thus the offending matter will be diluted and evacuated both by vomit and stool. The clysters may be repeated as often as they return, at least until the pain abates.

Instead of chicken water, as advised by Sydenham, barley water may be used, or water impregnated with any insipid mucilage; butter milk, which some prefer above every liquid; gentle acid drinks; or a decoction

of oat (or other) bread, that is first toasted, until it is brown as coffee, but not burnt, may be employed: as much of this toasted bread should be boiled in the water as will render the decoction of the colour of weak coffee. Edinburgh Med. Essays.

These liquors should be plentifully drank, until the contents of the bowels are sufficiently evacuated to render the exhibition of opium safe.

If the pain and sickness be violent, and the vomiting slight and ineffectual, from a quarter to half a grain of tart. emet. may be given in part of the drink, every three or four hours; or, if the discharge by stool be inefficient, such mild laxatives as the stomach will bear may be added. Manna is well adapted to this purpose, and may be given with tamarinds.

When the strength is reduced by the evacuations, and the primæ viæ cleared, the vomiting and purging may be checked with opiates. Sydenham directs the tinct. opii, from twelve to twenty drops, or more, in a little mint water, to be repeated two or three times a day, or oftener, as the urgency of the pain or frequency of the evacuations require, and to be continued, at least night and morning, until the patient recovers some degree of strength. Opiates are often, however, in a moment rejected; and, in this case, a small pill of solid opium will elude the action of the stomach, and check the vomiting. This, too, sometimes is rejected; and we have then given with advantage, a teaspoonful of elixir pargoric frequently, which is lost about the fauces, but its effects are communicated by degrees to the stomach.

If the disorder hath continued some hours, and the patient is already weakened, the opiates may be immediately given and continued, as already directed. If the symptoms of weakness are extreme, the pulse weak and intermitting, and convulsions approaching, twenty-five or thirty drops of the tincture of opium should be given in a large spoonful or two of strong cinnamon water, and after it a draught of whatever liquor the patient hath to drink, mixed with an equal quantity of wine.

The saline draughts given in the act of fermentation often allay the vomiting very soon: they may be repeated after each evacuation upwards, and to these some tincture of opium may be added.

A free use of the cclumbo root will be sometimes an adequate remedy against this dangerous disease. It is said rarely to require any means to be employed for promoting the discharge of bile, or to cleanse the primæ viæ, previous to its administration. As soon as assistance is demanded, from ʒss. to ʒij. of this medicine, finely powdered, may be given in a glass of peppermint water, and repeated every three or four hours, according to the urgency of the symptoms. In hot climates this remedy is almost a specific: it soon abates the violent evacuations; and by continuing it a few days, every other symptom vanishes.

Hoffman observes, that in choleræ and bilious diarrhœas, especially such as are excited by passion, it is necessary to abstain from sudorifics and a sudorific regimen, particularly at the beginning; these being apt to bring on a violent rheumatic or arthritic affection.

The cholera morbus sometimes destroys the patient in twenty-four hours. If it is cured, the patient is much relieved in two or three days: it rarely continues a

week, except it is the forerunner of some other disease. See *Arctæus*, *Cœlius Aurelianus*, *Hoffman*, *Fordyce's Elem.* p. 2. *Edinb. Med. Ess.* vol. v. *Wallis's Sydenham.* Cullen's *First Lines*, vol. iv. 39.

CHO'LERA SI'CCA. See *COLICA*.

CHOLE'ERICA, (from *χολερα*, *cholera*). Medicines which relieve the cholera. See also *DIARRHŒA HEPATARRHŒA*.

CHOLICELE. A swelling on the right side, or rather near the pit of the stomach, from an accumulation of bile in the gall bladder.

CHOLOBA'PHINON, (from *χολη*, *bile*, and *βαπτω*, *to immerge*). A metal resembling gold, and which appears as if it had been dipt in gall. See *Æs*.

CHOLO'MA, (from *χωλος*, *lame*, *maimed*). Galen observes that in *Hippocrates* it signifies a distortion of a limb. In a particular sense, it is taken for a halting, or lameness in the leg.

CHOLO'SIS, (from *χωλος*, *lame*). In *Vogel's Nosology*, this is a genus of disease which he defines to be lameness, from one leg being shorter than the other. It is sometimes the case with children, that one leg seems longer than the other, and the motion of the longer leg is rotatory in consequence of it. *Mr. Pott* thinks, that this is owing to a paralysis of the part. In these instances, the *glutæi* muscles and the ligaments are in a very relaxed state, and the disease most probably, in a very great measure, originates from weakness. Amongst the most useful means of relief are, the cold bath, the bark, iron, setons, and vitriolic acid.

CHONDRI'LLA, vel CONDRI'LLA, (from *χονδρον*, *a grain of any corn*; so called, because it emits small particles of gum resembling grain). It is a species of succory, the root of which is perennial, and the leaves minutely indented.

The only species of chondrilla in the *Species Plantarum*, is the *C. juncea* Sp. Pl. 1120; and the different species of former authors are dispersed under the preceding and following genera, *lactuca*, and *frenanthes*; but no species has the slightest pretence to any medicinal power, though the gum of the *lactuca perennis*, the *chondrilla cœrulea* of *Casper Bauhine*, has been used as an emmenagogue.

CHONDROGLO'SSUS, (from *χονδρον*, *a cartilage*, and *γλωσση*, *a tongue*). A muscle inserted into the basis, or cartilaginous part of the tongue. See *HYOGLOSSUS*.

CHO'NDROS, (from *χεω*, *to pour out*, and *ὕδωρ*, *water*; from the manner, according to *Schrevelius*, in which the food of the ancients called *Alica* was made). See *ALICA CARTILAGO*, and *XIPHOIDES CARTILAGO*. It also signifies any grumous concretion, as of mastic, &c.

CHONDROSYNDE'SMUS. A cartilaginous ligament. (From *χονδρος*, *cartilago*, and *συνδεσμος*, *connectio*).

CHONDROPHARYNGÆ'US, (from *χονδρος*, *a cartilage*, and *φαρυγξ*, *the upper part of the fauces*). See *PHARYNX*. A muscle which rises from the cartilaginous appendage of the os hyoides, and is inserted in the membrane of the fauces. *Douglass*.

CHO'NE. See *INFUNDIBULUM*.

CHO'PIN. An English WINE QUART.

CHOPI'NO. A CHOPINE; also *cheopina*, which see.

A pint measure at Paris, containing fifteen ounces and a half, or sixteen ounces.

CHO'RA. A REGION, (from *χωρος*, *a place*). *Galen*, in his work *De Usu Part.* expresses by it particularly the cavities of the eyes; but in other places he means by it any void space.

CHO'RDA, *χορδη*, (from *χορδευω*, *to roll up like a cord*). Properly a musical chord, metaphorically a tendon. Poets often express by it the intestines. *Paracelsus*, in his work *De Origine et Curatione Morbi Gallici*, calls the penis by this name. A painful tension of the penis in the lues venerea is still called *chordé*.

CHO'RDA MAGNA. See *TENDO ACHILLIS*.

CHO'RDA TYMPANI. The fifth pair of nerves from the brain divides into three principal branches, one of which is called the inferior maxillary. (See *TRIGEMINI NERVI*). A branch of the inferior maxillary nerve forms the lingual, which, soon after it leaves its origin, is accompanied by a small distinct nerve, which runs upward and backward towards the articulation of the lower jaw, in company with the lateral muscle of the malleus, and passes through the tympanum between the handle of the malleus and the long neck of the incus, by the name of the *chorda tympani*. It afterwards perforates the back side of the tympanum, and unites with the portio dura of the auditory nerve.

CHO'RDÆ TENDI'NEÆ. See *COR*.

CHO'RDÆ WILLISII. See *DURA MATER*.

CHORDA'PSUS, (from *χορδη*, *a cord*, and *απτω*, *to knit*; so called, from the intestines appearing to be twisted into knots, like pieces of string, in a species of painful colic). See *COLICA*, and *ILIACA PASSIO*.

CIORDA'TA GONORRHŒA. A gonorrhœa attended with chordee, or painful tension of the penis. See *GONORRHŒA*.

CHORDE'. See *CHORDA*. It is a painful involuntary erection of the penis, happening at all times, but more commonly when the patient is warm in bed; under which circumstance, the penis is not only hard and painful to the touch, but generally bent downwards in a considerable degree. It sometimes remains after the heat of urine and other symptoms of gonorrhœa have disappeared; but is usually more severe during the continuance of the inflammation, and becomes more or less violent according to the greater or less degree of that symptom.

*Astruc* distinguishes two species; when the whole body of the penis is regularly drawn downwards in the form of a semicircle, from inflammation, an ulcer in the membrane of the urethra, or in its corpus cavernosum; or when the glans only is drawn down by inflammation of the frænum. He also observes, that, besides the chordee, there are other distortions of the penis. If the suspensory ligament that connects the penis to the os pubis is inflamed, or if only one of its cavernous bodies is injured, the penis will either be bent upwards or to one side; and these are relieved in the same manner as the chordee.

*Dr. Rutherford*, in his *Clinical Lectures*, supposes that inflammation and swelling in the corpus cavernosum urethræ is the cause of the chordee; and *Mr. Bell*, that the irritation is communicated to the contiguous muscles, producing unequal degrees of con-

traction over the whole substance of the penis which universally takes place in this disease. Neither explanation is, however, satisfactory; nor can we attribute it to any cause but a spasm in the cells of the corpora cavernosa, and an irregular distribution of the blood. It has not, however, yet been shown that these cellular parts are muscular.

If the patient is costive, gentle laxatives should be administered; and in full habits, bleeding is essentially necessary. A cold solution of acetated litharge, or the camphorated oil, applied to the part, and sleeping in tight drawers, have been recommended. Rubbing the parts with tincture of opium, or a strong solution of it in water, or pledgets immersed in either, kept upon the parts, have been found useful. Emollient injections, impregnated with opium, are exceedingly efficacious in lessening the violence of this complaint: but taking thirty or forty drops of tincture of opium at bed time is the remedy mostly to be depended upon, as it seldom fails to prevent or remove the affection: and this is considered as one of the most effectual remedies in every stage of this symptom, particularly where it has been of long continuance. If opium fails, the hyoscyamus niger may be tried, beginning with one grain of the extract, and gradually increasing the dose, according to its effects. Though, in slight degrees of chorea, blood letting is never necessary; still, whenever, it is severe, particularly if the habit is plethoric, and the pulse strong and full, it should never be omitted; and, perhaps, the best mode is by the application of leeches to the part affected; particularly as it prevents the chorea remaining after every other symptom of gonorrhœa has disappeared, which is sometimes the case. Frictions, with mercurial ointment, have been strongly recommended; but they are generally unnecessary, and often useless.

See Astruc, Foot, Hunter, Bell, and Swediaur, on the Venereal Disease.

**CHO'REA SANCTI VITI**, (a χορος, *cætus saltantium*). **St VITUS' DANCE**. Also called *viti saltus*; by Paracelsus, *lascivus*. Horstius observes, that some women, who were disordered in mind, once every year paid a visit to the chapel of St. Vitus, near Ulm, and there exercised themselves day and night in dancing, till they were completely exhausted. Thus they were restored till the return of the following May, when they were again seized with a restlessness and disorderly motion of their limbs, in so great a degree as to be obliged, at the anniversary feast of St. Vitus, to repair again to the same chapel for the sake of dancing. From this tradition, a convulsion, to which girls are principally subject before the eruption of the menses, took its name. The disorder, however, above described by Horstius is different from what we call *St. Vitus' dance*.

Mead and Pitcairn think this disorder paralytic; Sydenham considers it as convulsive; Dr. Cullen calls it *chorea*, and has, on account of the age at which it attacks, as well as the motions which it exhibits, established it as a genus, under the class *neuroses*, and order *spasmi*. He remarks, that it affects those of either sex before the time of puberty, for the most part between the tenth and fourteenth years. It manifests itself by involuntary convulsive motions of some parts,

commonly of one side, resembling the gestures of buffoons, in the movement of the arms and hands; the patients, in walking, oftener drag one foot than raise it.

Sydenham thus describes it: "A kind of convulsion, which principally attacks children of both sexes from ten to fourteen years of age. It first shows itself by a lameness, or rather unsteadiness, of one of the legs, which the patient draws after him like an idiot, and afterwards affects the hand on the same side, which, being brought to the breast, or any other, part, can by no means be held in the same posture for a moment, but is distorted or snatched by a kind of convulsion into a different posture or place, notwithstanding all possible efforts to the contrary. If a glass of liquor be put into the hand to drink, before the patient can get it into his mouth, he uses a thousand odd gestures; for, not being able to carry it in a straight line thereto, because his hand is drawn different ways by the convulsion, as soon as it hath reached his lips, he throws it suddenly into his mouth, and drinks it very hastily, as if he only meant to divert the spectators."

This is, however, a very imperfect and inadequate view of the disease. We shall, therefore, transcribe that given by Dr. Hamilton, in his Treatise on the Utility of Purgatives.

"Chorea Sancti Viti attacks boys and girls indiscriminately; and those chiefly who are of a weak constitution, or whose natural good health and vigour have been impaired by confinement, or by the use of scanty or improper nourishment. It appears most commonly from the eighth to the fourteenth year. I saw it in two young women, who were from sixteen to eighteen years of age.

"The approaches of chorea are slow. A variable, and often a ravenous, appetite, loss of usual vivacity and playfulness, a swelling and hardness of the lower belly in most cases, in some a lank and soft belly, and, in general, a constipated state of the bowels, aggravated as the disease advances, and slight irregular involuntary motions of different muscles, particularly of those of the face, which are thought to be the effect of irritation, precede the more violent convulsive motions, which now attract the attention of the friends of the patient.

"These convulsive motions vary. The muscles of the extremities and of the face, those moving the lower jaw, the head, and the trunk of the body, are at different times, and in different instances, affected by it. In this state the patient does not walk steadily; his gait resembles a jumping or starting; he sometimes cannot walk, and seems palsied; he cannot perform the common and necessary motions with the affected arms.

"This convulsive motion is more or less violent, and is constant, except during sleep, when, in most instances, it ceases altogether. Although different muscles are sometimes successively convulsed, yet, in general, the muscles affected in the early part of the disease remain so during the course of it.

"Articulation is now impeded, and is frequently completely suspended. Deglutition is also occasionally performed with difficulty. The eye loses its lustre and intelligence; the countenance is pale, and expressive of vacancy and languor. These circumstances

give the patient a fatuous appearance. Indeed, there is every reason to believe, that, when the complaint has subsisted for some time, fatuity, to a certain extent, interrupts the exercise of the mental faculties.

"Fever, such as arises in marasmus, is not a necessary attendant on chorea; nevertheless, in the advanced periods of the disease, flaccidity and wasting of the muscular flesh take place, the consequences of constant irritation, of abating appetite, and impaired digestion, the common attendants of protracted chorea; and which, I doubt not, may, in some instances, although contrary to the opinion that chorea is not fatal, have been the forerunners of death."

This is a very faithful picture of the disease, and we can only add to it, that the belly seems often obstinately bound. We have seen it at every age, from seven to twenty-two; and, in one case, it occurred in a young woman of twenty, who had been married about three weeks.

What can have occasioned the apathy of practitioners respecting this frightful complaint, it is not easy to say. The description of Sydenham has been repeated in every author, and the usual tonics and antispasmodics indiscriminately and fruitlessly advised. The disease evidently depends on debility; but we can no more conquer this debility by tonics, than we can successfully combat that which arises from infarcted viscera by bark. It seems to have escaped authors that, in every case of chorea, there is a load in the head, an obstructed discharge from the bowels, at a time when it is the object of nature to determine the fluids to the lower belly, viz. about the age of puberty. Many of the symptoms are those of apoplexy or palsy; but, as usual in cases of debility, the voluntary muscles lose their balance, and convulsions follow.

Those who have once suffered under this disease are very subject to a relapse. However violent the symptoms, they never are suddenly destructive. When recent in a young person, of an otherwise good constitution, there is hope of a speedy cure. If the menses are obstructed, their return will mitigate, if not cure, the disease. If the temperament is very sensible, the disease hereditary or habitual, the cure is difficult.

Nothing, in the records of medicine, is more trifling and indiscriminate, than the mode recommended of relieving chorea. The author of this article, more than twenty years since, catching the hint from Sydenham, gave purgatives; and found that this usually obstinate disease yielded not only soon, but with little danger of relapse; and, in this interval, he has had occasion to see more than sixty cases, three times Dr. Hamilton's boasted number, in one of which only he may have been styled unsuccessful. The violence of the disease, indeed, in that instance, was subdued; but slight irregular motions, especially on any sudden agitation, would not yield. The author's own illness obliged him to refer the patient to another physician, but every measure seems to have failed.

The choice of the purgative appears of little importance; but it must be active, for no other will produce the necessary discharge; and the saline purgatives are apparently less adapted to the complaint. The author knows no distinction but in their power. The most active are the most useful. In the Edinburgh Medical Journal, there are two cases of chorea in which purga-

tives succeeded; and, in Dr. Hamilton's volume, there are many instances of well conducted successful treatment by this plan. We have had no reason to follow the purgatives by tonics. The constitution has restored the general health with rapidity and effect. We may just add, that, in the woman newly married, the complaint yielded, within a fortnight, to the purgative course.

See Wallis's Sydenham, vol. ii. p. 327; Cullen's First Lines, vol. iii. edit. 4. Hamilton on Purgative Medicines; Edinburgh Medical Journal, vol. i.

CHO'RION. *Membrana externa, quâ fœtus involvitur*, (from *χώρα*, *receptaculum*). Vide H. Steph. Thes. Sometimes called *camisia fœtus*, SHIRT OF THE FÆTUS. A name of the external membrane of the fœtus. In women, as in some animals, the chorion, at the first, is without any sensible placenta. It is also said to have its name from the chorus or crowd of blood vessels which are spread on it. It adheres to the amnios by a gelatinous substance, and is divisible into two lamellæ; the internal, or true chorion, is even more thin and pellucid than the amnios; whilst the external, or false chorion, is thick and opaque. This spongy chorion adheres to the uterus at every part, and grows thicker as it approaches the placenta; whilst the internal lamina adheres inseparably to the inner surface of the placenta: hence it is plain, that the substance of the placenta is betwixt these two lamellæ of the chorion. This membrane hath numerous lymphatic vessels; but in the human placenta, these vessels cannot be traced by injection on the amnios and chorion. The uterus, indeed, sends veins to the outer chorion; and perhaps the arteries do the same. See DECIDUA.

The use of the chorion is to sustain the umbilical vessels.

CHOROIDES, (from *χοριον*, *chorion*, and *ειδος*, *likeness*). It is an epithet of several membranes, which, on account of the multitude of their blood vessels, resemble the chorion. It is the *tunica retiformis oculi*, a name of one of the coats of the eye. (See RETIFORMIS.) It lines the sclerotis; is a thin vascular coat of a brownish colour, and generally said to derive its origin from the pia mater covering of the optic nerve. From the colour of part of this membrane it hath been called *uvea*; the external surface of which is called the *iris*; but at present the entire fore part only of this coat is called *iris*; and the rest *choroides*. It consists of two laminæ; the exterior is slightly connected with the sclerotica, and is also covered with a black matter, called *nigrum pigmentum*. Both laminæ are extremely vascular: the extremities of the vessels of the inner surface project from it, and are termed *villi* and *papillæ*. As this internal lamina was first noted by Ruysch, it is called *Ruyschiana tunica*. The black substance which lies between the sclerotica and choroides, is also found betwixt it and the retina. Near where the sclerotica becomes transparent, the choroides is firmly united to it; and, at this circle of adhesion, the choroides seems to change its colour and texture, appearing as a whitish ring, of a compact substance, and is termed *ciliare ligamentum*. Here the internal lamina of the choroides dips inwards, to make what are termed the processes. The ciliary processes are on the inside, between the iris and choroides, as the ligamentum ciliare is on the outside. The choroides is continued on the inside of the transparent part of the sclerotis, and there forms the iris: the per-

foration in the middle is called *pupilla*. The artery is a branch of the carotid. The veins empty themselves into the optic sinuses, which are again discharged into the internal jugulars; but some of these veins communicate with the external veins of the eye, so that part of the blood is emptied into the external jugulars. The nerves are from the ophthalmic branch of the fifth pair, and a branch of the third pair.

Opposite to the insertion of the optic nerve, the choroïdes is wanting: and thus is formed that white speck, on which, if the picture of an object falls, we are incapable of perceiving it.

CHOROÏDES PLEXUS. A plexus of blood vessels; a congeries of blood vessels on the lateral ventricles of the brain. See CEREBRUM.

CHOU DE PALMI'STE. (French.) The cabbage of the palm tree. See PALMA NOBILIS.

CHOWDER, is an antiscorbutic, used on the Newfoundland station, and consists only of fresh fish boiled with the salted ship provisions.

CHOWDER BEER, is an infusion of spruce in water, from which beer is prepared in the common way.

CHRISTI MA'NUS. See SACCHARUM.

CHRISTOS, (from *χρίω*, to anoint). Whatever is applied by way of unction.

CHROME. A newly discovered metal. See CHEMISTRY.

CHRONICUS, or CHRO'NIUS, (from *χρονος*, time). CHRONICAL.

Diseases which continue long, and are without any, or at least a considerable degree of, fever. On the contrary, those which proceed rapidly, and terminate soon, are termed acute.

In the cure of chronical disorders, Dr. Fothergill intimates, that those means or medicines which enable the stomach duly to perform its office, are the most effectual, if not the only remedies. (See Lond. Med. Obs. vol. i. p. 314.) Dr. Cadogan seems to corroborate this, by his observations on the causes of chronical disorders; which, he says, are indolence, intemperance, or vexation: though now and then he allows, that an acute disorder, imperfectly cured, may be the cause of chronical ones. (See his Essay on the Gout and Chronical Diseases.) In general, however, chronical diseases depend on an obstructed discharge, or an infarcted gland, usually the liver. Atonic gout may be another cause; but, in general, an attention to the state of the bowels is essentially necessary, and a preservation of the balance of the circulation, particularly an attention to the warmth of the surface and extremities. Wallis's Sydenham, vol. i. p. 4.

CHROS, (from *χρῶα*, the skin). Galen says, that the Iōnians mean, by this word, the flesh in our bodies; i. e. all except bones and cartilages.

CHRU'PSIA, (from *χρῶα*, colour, and *ὄψια*, sight). A disease in the eyes, in which the person perceives objects of colours different from their real ones.

CHRYPSO'RCES. See PARORCHIDIUM.

CHRYSA'NTHEMUM, (from *χρυσος*, aurum, and *ανθεμος*, a flower). Called also *bellis lutea foliis profunde incisus major*; *chrysanthemum segetum* Lin. Sp. Pl. 1254; CORN MARIGOLD. It is an annual plant, frequently met with amongst corn. The Germans commend it in the jaundice; but it is not employed in practice with us.

It is likewise a name for the GARDEN MARIGOLD, and many other herbs, whose flowers are of a bright yellow colour. See CALENDULA.

CHRYSA'NTHEMUM BIDENS. See ACME'LLA.

CHRYSA'NTHEMUM COTU'LE FO'LIO. See BUPHTHALMUM VERUM.

CHRYSA'NTHEMUM I'NDICUM. See BATTATAS CANADENSIS.

CHRYSA'NTHEMUM LEUCA'NTHEMUM. See BELLIS MAJOR. It is also the name for several species of *sunflower*, *cotula*, and the common *ox eye*.

CHRYSA'TTICUM. An epithet of a sort of pas-sum, recommended by P. Ægineta to be drunk with the seed of atriplex for the jaundice.

CHRY'SE. The name of a yellow plaster in P. Ægineta for fresh wounds; from *χρυσος*, gold.

CHRYISISCE'PTRUM, (from *χρυσος*, gold, and *σκηπτρον*, a rod, or staff, so named from the yellow colour of its stem). See VIRGA AUREA.

CHRYSI'TIS, or CHRYSI'TIS SPO'DOS, (from *χρυσος*, aurum). See LITHARGYRUM.

CHRYSOBALA'NUS GALE'NI, (from *χρυσος*, and *βαλανος*, a nut, on account of its colour). See NUX MOSCHATA.

CHRYSOCA'LLIA. See CHAMÆMELUM.

CHRYSO-CERAU'NIUS, (from *χρυσος*, gold, and *κεραυνος*, thunder). See AURUM FULMINANS.

CHRYSOCHA'LCUM, (from *χρυσος*, and *χαλκος*, brass). See ÆSECIVM.

CHRYSOCO'LLA, (from *χρυσος*, gold, and *κολλη*, glue, or solder). See TINCAL and BORAX.

CHRYSOCO'MA, (from *χρυσος*, gold, and *κομη*, hair, from its resembling golden hair). See ELICHRYSUM.

CHRYSO'GONUM, (from *χρυσος*, and *γονυ*, a knot). RED TURNIP.

CHRYSOLA'CHANON, (from *χρυσος*, and *λαχανον*, the *olus*; so called from its leaf and root being yellow like the *olus*). See ATRIPLEX.

CHRYSOME'LIA, (from *χρυσος*, and *μηλον*, an *apple*). See AURANTIA HISPANICA.

CHRYSO'PUS, (from *χρυσος*, and *ωψ*, face or appearance). See GAMBOGIA.

CHRY'STALS, and CHRY'STALLOGRAPHY. This subject can scarcely be considered as a medical one, since, perhaps, the deposition of bony matter, more certainly calculous concretions, are the only instances of crystallization in the human body. Yet, as chemistry has made such gradual and effectual encroachments on medicine, and as the variety of crystals are often mentioned in these pages, a short account of this subject is, in every view, necessary and proper.

Linnæus, who made, very early, some imperfect and ineffectual attempts to arrange minerals from their external appearances, spoke of the more obvious and common forms, which salts and other bodies assume, when passing from a state of fluidity to that of a solid. The chemical mineralogists, who, under the guidance of Cronstedt, succeeded, turned the attention of philosophers from the obvious properties to the component parts; when, in 1772, the first edition of Romé de l'Isle's *Chrysallography* appeared; and the second edition, in five volumes, was published in 1783. About this period Bergman, in a separate dissertation, greatly illustrated the subject. Since that time, the attention of

mineralogists was again directed to external forms, by the abbé Haüy; who, in numerous papers, published in the *Journal des Mines*, and afterwards, in 1801, in a separate work, in four volumes octavo, explained, with mathematical accuracy, all the different forms of crystals; taught us the mode of their construction, by a successive application of molecules; and pointed out the way in which the primitive crystal may be detected. The form of the crystals, in a great variety of solids, has thus been traced; and so constant is the crystallization of the same ingredients, that, in more than one instance, the crystallographer has instructed the chemist; in general, his fiat has confirmed the chemical analysis.

**CHRY'SUN**, (from χρυσός, *gold*). An epithet of two collyria for the eyes, and also of two pessaries for the uterus, in Ætius.

**CHU**, or **CHUS**. The name of a measure. The same as **CHOA**, *congius*. This was a liquid measure among the Athenians, containing six sextarii, twelve Attic cotylæ, or nine pints or pounds of oil, ten of wine, thirteen and a half of honey, according to Galen. Linden says, at least eight of wine and four ounces. Rhodius asserts, that the *chus*, or *congius*, weighs ten pounds. Castelli.

**CHUNDRILLA VERCURIA**. See **ZACINTHA**.

**CHU'NNO**. See **BATTATAS**.

**CHYLA'RIA**, (from χυλός, *chyle*). See **DYSURIA**.

**CHYLIFERA VASA**, (from χυλός, *chyle*, and φέρω, *to carry*). See **LACTEA VASA**.

**CHYLIFICA'TIO**, (from χυλός, and *facio*, *to make*).

**CHYLIFICATION**. The first digestion, or the changing of the aliment into chyle. See **DIGESTION**.

**CHYLIS'MA**, (from χυλός, *juice*). In Dioscorides it signifies expressed juice.

**CHYLISTA**. Hartman's chylista is glass of antimony obtunded by levigating it with mastich dissolved in rectified spirit of wine.

**CHYLOPOI'ETIC**, (from χυλός, *chylus*, and ποίω, *facio*), applied to the organs which form chyle.

**CHYLO'SIS**, (from χυλίζω, *to express the juice*). See **CHYLIFICATION**.

**CHYLOSTA'GMA DIAPHORE'TICUM MINDERERI**, (from χυλός, *juice*, and σταζω, *to distil*); called also *theriacalis bezoardica aqua*. It is a fluid distilled from the theriaca Andromachi, or from Mithridate.

**CHY'LUS**, χυλός, (from χυλός, *juice*), called, in Paracelsus, *chymosum*. In general it is a juice inspissated to a middle consistence between fluid and dry.

In Hippocrates the word χυλός is used to express the juice and sorbile liquor of barley, called strained ptisan, being the expressed substance of the barley; not what the Latins called *cremor*, which is only the barley water. To χυλός is opposed ptisan unstrained.

By chyle, however, is commonly meant the oily part of our aliment, mixed with the saliva and other juices poured into the stomach and duodenum. It assumes the form of chyle only in the duodenum, since it never appears in the lymphatics of the stomach. It is apparently an uniform fluid, whatever be the food employed, or the animal in whose stomach it is digested. It has been supposed, though without sufficient foundation, to resemble milk; but milk in the stomach is not absorbed till it has undergone the digestive process, and milk injected into the blood vessels produces the most

formidable symptoms. The real nature of chyle is not known. It seems to consist of a serous and a coagulable part, with distinct globules, which give it opacity, and have been supposed, rather than proved, to be oily. The small quantity of chyle that can be obtained, is the reason why its nature has not been more carefully examined.

The chyle, when it enters the blood, does not immediately mix with it, but in many instances seems to pass in a separate state through the whole circulation: for the chyle has been seen to float on the surface of blood, when taken from the arm: in the last stage of a diabetes, the urine manifestly points out the presence of chyle in it. See Haller's *Physiology on the chyloferous vessels*.

**CHYMA'TION**. The name of a penetrating medicine in Marcellus Empiricus.

**CHY'MIA**. See **CHEMIA**.

**CHYMIA'TRIA**, (from χυμία, *chemistry*, and ἰατρεία, *healing*). The art of curing diseases by chemical medicines.

**CHYMO'SIS**, (from χαίνω, *to gape*). It is when, from inflammation, the white of the eyes swells above the black circle, so that there appears a gaping aperture. Galen, de Euphoristis, calls it a red and carnosus inflammation of the cornea tunica. Paulus calls it *chemosis*, when, from a vehement inflammation, both the eye lids are turned outwards, so as scarcely to cover the eye, and the white of the eye appears higher than the black, and partly hides it. Le Dran calls it a tumour on the white of the eye.

It is really a species of ophthalmia, called by Sauvages **OPHTHALMIA CHEMA'SIS**, and by De Meesrey, **TRAUMATICA**. The **CHEMOSIC**, or **CONJUNCTIVA CORNEA PALPEBRARUM OPHTHALMY**. Sauvages ascribes it to an external cause, as a violent contusion of the eye, whence an hyposphagma, or to a surgical operation performed on the eye, as an extraction of a cataract; to the operation for the unguis, or empyesis, or to an internal cause, as metastasis, or severe catarrh in cacochymic habits. It is known by the black red swelling of the conjunctiva, with a depression and obscurity of the cornea, which seems to lie, as it were, in a cavity. The inflammation is severe, with excruciating pains of the eyes and head, and a sense of weight above the orbit; pervigilium, fever, pulsation, a swelling, and shutting of the eye lids. It terminates sometimes in the suppuration of the eye, and an irremediable blindness or leucomata succeed.

In Dr. Cullen's *Nosology*, it is a variety of that species of ophthalmia which he names the *ophthalmia membranarum*. When the ophthalmia is in this state, it is for the most part accompanied with violent pain; the white part of the eye resembles raw flesh, or sometimes the pile of red velvet. All the transparent part of the cornea often comes away by suppuration, which destroys the anterior chamber of the eye. The cicatrix, subsequent to the suppuration, hinders the crystalline and vitreous humours from falling out, and by that means the entire destruction of the globe is prevented: sometimes, however, both happen. This disease is often fatal; loss of sight generally follows, and the pain sometimes destroys the patient.

The violence of the disease requires the speediest and

most powerful aids. Repeated bleeding, according to the strength of the patient, with the most active purges, chiefly of the saline kind, will be necessary. A blister may be applied on the forehead, or leeches to the temples; and after them a blister over the part where they were applied. Goulard's saturnine poultice may be applied cold over the eye lids, and renewed as often as it grows warm. Antimonial diaphoretics may be given inwardly, and opium in the largest doses is indispensable. Indeed every method ought to be pursued which can most immediately subdue the inflammatory symptoms. See Nosologia Methodica Oculorum, with Notes by Dr. Wallis, and Ophthalmia.

CHYMO'SUM, (from *χυμος*, *succus*). See CHYLUS.

CHYMUS, *χυμος*, HUMOUR OR JUICE, (from *χυνω*, *fundo*, *to pour out*). In the common signification of the word it is every kind of fluid which is incrassated by concoction. Sometimes it means the finest part of the chyle when separated from the fæces; but in general it implies the food in the state in which it passes out of the stomach previous to its mixing with the bile. In Galen, it is the faculty or quality in plants and animals which is the object of our taste.

CHYTION, (from *χυνω*, *to pour out*). In Hippocrates it means a plentiful inunction with oil and water.

CIBA'RIOUS, SAL. See MARINUM SAL.

CIBA'TIO, (from *cibus*, *food*). By this is meant the assumption of aliment; synonymous also with the application of the nutritious juices.

CIBORIUM, CIBORIUM, (from *κιβωριος*, *a bag*, which its pods resemble.) See FABÆ ÆGYPTIÆ.

CIBOUL. A sort of ONION nearly allied to the scallion. They have no bulb at the root, and are cultivated in the kitchen garden.

CIBUS, from the Hebrew term *kibash*, *food*, or *nourishment*.

CIBUS ALBUS. WHITE FOOD. It is a species of jelly, which in Fuller's Pharmacopœia is thus made: take four pints of milk, the breast of a boiled capon, and two ounces of blanched sweet almonds; let them be well beat, then boil them over a gentle fire, adding three ounces of rice meal. When they begin to coagulate, add eight ounces of white sugar, and ten spoonfuls of rose water: mix all well together.

The Spaniards give the name of *cibus albus* to a certain American plant. But by WHITE MEATS we now mean milk, butter, cheese, custards, and other foods consisting of milk or eggs; as WHITE POT, made of milk or cream, baked with the yolks of eggs, fine bread or rice, sugar, and spice, in an earthen vessel. There are a variety of dishes under this denomination; but, strictly speaking, white meats are fish, veal, and chicken.

CICA'DA, (*quod cito cadit*, *because it soon disappears*). The BAUM CRICKET. It hath wings, is very noisy, and is said to live on dew, which it sucks from the dwarf ash or manna tree. Its species we cannot ascertain, though we have examined all those of Gmelin, amounting to 237. These insects, when dried and burnt, are used in the colic or stone as a solvent.

CICATRISANTIA, (from *cicatrigo*, *to skin over*). See EPULOTICA.

CICA'TRIX, (from the same). A seam or elevation of callous flesh, on the skin, after the healing of a wound or ulcer, commonly called a *scar*.

It is the destruction of the cellular membrane by inflammation that causes cicatrices to be drawn inwards. Some commend the steams of hot water to be often applied to the growing skin to prevent a cicatrix, and to dress the wound with a cerate of wax and the oil of eggs.

CICER, (from *kikkar*, *a round mass*), *album*, *nigrum*, vel *rubrum*; *cicer sativum*, *cicer arietinum*, *erebinthus*; CHI'CHES, CICHES, CICERS, CICH PEAS, and VETCH. The sort used as aliment is the *cicer arietinum* Lin. Sp. Pl. 1040.

Chiches, a leguminous plant, cultivated in warmer climates, where our finer peas do not thrive so well. They are a strong flatulent food, hard of digestion. They are sown in France, Italy, &c. flower in June, and the peas are ripe in July.

CIC'ERA, (from *cicer*, because of their size).

CIC'ERA TAR'TARI. Small pills composed of turpentine and cream of tartar, of the size of a vetch.

CICHO'REUM, CICHORIUM, (*γυπαριον το δια των χωριων κειν*, *because it creeps about and scatters itself in the fields*). *Sylvestre*, and *sativum*. WILD and GARDEN SUCCORY. The wild is the *cichorium intybus* Lin. Sp. Pl. 1142.

It is a plant with oblong, dark green, hairy leaves, deeply jagged, like those of dandelion, but larger; in the bosoms of which, towards the tops of the branches, the flowers come forth in spikes, consisting each of a number of blue flat flosculi, set in a scaly cup, which afterwards become a covering to several short angular seeds: the root is long and slender, of a brown colour on the outside, and white within. It is biennial, grows in hedges and by road sides, and flowers in June and July.

It abounds with a milky juice, of a penetrating bitterish taste, and of no remarkable smell: the roots are bitterer than the leaves or stalks, and these much more so than the flowers. But by culture in gardens it loses its green colour, and in a great measure its bitterness, and in this state is a common salad herb: the deeper coloured and the deeper jagged the leaves are, the bitterer is the taste of the whole plant, which is mildly aperient, and, if freely used, it loosens the belly. The virtue resides in the milky juice, which may be extracted by boiling in water, or by pressure. The wild and the garden sorts are used indifferently, and chiefly as food. If the root is cut into small pieces, dried and roasted, it resembles coffee, and is sometimes a good substitute for it.

CICHO'REUM LATIFO'LIUM. See ENDIVIA.

CICHO'REUM VERRUCA'RIMUM. See ZACINTHA.

CICILIA'NA. See ANDROSÆMUM.

CICINDE'LA, (a dim. of *candela*, i. e. *a little candle*; so called from its light). The GLOW-WORM, also called *λαμπουρις*, *noctiluca terrestris*, *scurebæus*, *cicendela mas et femina*.

The flying glow worms are males, and the creeping ones the females. Some think them anodyne, others lithontriptic; though probably neither.

CICINI OL. (from *κικιν*, *the ricinus*). See RICINI OL. under CATAPUTIA.

CIC'IS, *κικις*. In some places of Hippocrates and Theophrastus it is put for *κηκίς*. A GALL. See GALLÆ.

CIC'CLA. See BETA ALBA.

CICO'NGIUS. Blancard says it is a measure containing twelve sextaries or pints.

**CICO'NIA**, (from *Cicónes*, the people of Thrace, who held this bird in veneration). The STORK.

**CI'CUS**, (from *κικκος*, the core). The skin which envelopes the seed.

**CICU'TA**, (quasi *cæcuta*, blind, because it is said to destroy the sight of those who use it.) **HEMLOCK**; called by some *camarum*; by others *abitos*; and, according to Erotian, *cambeion* is an old Sicilian word for *cicuta*.

**CICU'TA MA'JOR FÆ'TIDA**. The *conium maculatum* Lin. Sp. Pl. 349. **SPOTTED HEMLOCK**. It grows wild in almost every climate, and with us is found about the sides of the fields, under hedges, and in moist shady places. It is a tall umbelliferous plant, with large leaves, of a blackish green colour on the upper side, and a whitish green underneath, divided into a number of small oblong somewhat oval segments, which stand in pairs on middle ribs; these segments are again deeply cut, but not quite divided on both sides; and many of these ultimate sections have one or two slighter indentations. They much resemble parsley or chervil, especially the leaves of the smallest sorts, whose poisonous quality is the most violent. The stalk is round, smooth, hollow, irregularly variegated with spots and streaks of a red or blackish purple colour; the flowers are white, and blow in June or July; the seeds greenish, flat on one side, very convex, and marked with five furrows on the other. The root is oblong, about the size of a middling parsnip, yellowish without, white and fungous within, and part of it hollow; it changes its form according to the season. The leaves have a rank smell, but do not much affect the taste.

Internally and externally it is narcotic and anodyne: it abates inflammations of the eyes; promotes rest, and eases pain, without producing thirst or headach the next morning, and as rarely creates costiveness; is supposed to possess a property of altering thin, corrosive cancerous ichor, and of rendering it mild. It hath been used with some advantage in sanious ulcers, cancers, gleet, painful discharges from the vagina, fixed pains supposed to arise from acrid serum, fluor albus, and scirrhus tubercles; but its efficacy is seldom permanent, and it injures the stomach, sometimes the constitution. Though it does not cure cancers, yet it is an anodyne more effectual than opium; and in phthisis is often useful for relieving pain and cough. It is useful in syphilis, according to Mr. John Hunter.

Dr. Cullen observes, that if hemlock, either in form of powder or extract, has no sensible effect when taken to twenty grains for a dose, the medicine may be supposed to be imperfect, and that if it is to be continued, another parcel of it should be employed. He adds, that he has known it useful in resolving and discussing scirrhusities of different kinds, particularly those of a scrofulous nature; in healing the ulcers of scirrhus tumours, which continued to be surrounded with such scirrhusity; and in some ulcers certainly that approached to the nature of cancer. In those that might be considered truly cancerous, he has known it relieve the pains, meliorate the quality of the matter proceeding from the sore, and even to make a considerable approach to its healing, though it never completed the cure. Mat. Med. It has been considered also as very useful in the chin cough and rheumatic complaints. See Butler on the Chin Cough.

When hemlock is imprudently eaten, it causes a vertigo, a dimness of sight, hiccough, madness, coldness of the extremities, convulsions, and death: sometimes by the spasms, which it produces in the stomach and other parts, hæmorrhages, or an epilepsy come on, which, without very speedy relief, are fatal. The proper method of relief is to discharge the contents of the stomach by means of the most active emetics, and then to administer frequent doses of sharp vinegar, as in the articles **AMANITA** and **VENENUM**.

The proper method of administering hemlock internally is to begin with a few grains of the powder or inspissated juice, and gradually to increase the dose until a giddiness affects the head, a motion is felt in the eyes, as if pressed outwards, with a slight sickness and trembling agitation of the body. One or more of these symptoms are the evidences of a full dose, which should be continued until they have ceased, and then after a few days the dose may be increased; for little advantage can be expected but by a continuance of the greatest quantity the patient can bear. In some constitutions even small doses greatly offend, occasioning spasms, heat and thirst; in such instances it will be of no service.

The college of physicians of London order the inspissated juice of hemlock, *succus cicutæ spissatus*, instead of the former extract, to be made in the following manner: let the expressed juice of hemlock, cleared from its fæces, be evaporated in a water bath saturated with sea salt to a proper consistence.

As the powder of the dried leaves has been thought to act, and may be depended upon, with more certainty than the extract, the following direction should be observed in the preparation: gather the plant about the end of June, when it is in flower; pick off the little leaves, and throw away the leaf stalks; dry the small selected leaves in a hot sun, or in a tin or pewter dish before the fire. Preserve them in bags made of strong brown paper, or powder them, and keep the powder in glass phials, where the light is excluded; for light dissipates the beautiful green colour very soon, and thus the medicine loses its appearance, if not its efficacy; this mode is recommended by Dr. Withering. The extract should also be made of the plant gathered at this period. That which grows in exposed places is generally stronger than what grows in the shade; and that in dry places is also to be preferred.

This plant has been taken a long time without any bad effect. When considerable inconveniences have arisen from its use, the *cicuta aquatica* has probably been mistaken for it. Externally it is applied with advantage, and particularly in the form of fomentation and poultice.

**FOTUS CICUTÆ**. *Hemlock fomentation*.—R. Fol. cicutæ recent. ℥ vi. vel sicca ℥ iij. coq. in aquæ fontanæ ℔ iij. et ℔ ij. et fiat fots. This is commonly made use of to foment cancerous or scrofulous ulcers, previous to the application of the succeeding cataplasm.

**CATAPLA'SMA CICU'TÆ**, *Hemlock cataplasm*.—R. Fotûs cicutæ, q. v. inspissetur avenæ farina ad crassitudinem cataplasmatum. This is not only applied in cancerous and scrofulous cases, but to inveterate ulcers, and very often both meliorates their discharge and lessens [their sensibility, though Mr. Justamond preferred the application of the fresh herb bruised. An ointment is also made of hemlock, by bruising the plant very well

in a marble mortar, then mixing with it an equal quantity of hog's lard, and gently melting them over the fire; afterwards the composition is to be strained and stirred till cold. This has been recommended to be applied to cancerous or scrofulous sores.

In this mode it has been useful in resolving some indurations, especially that of the scrofulous kind; but in the indolent scirrhusities in the breasts of women it is seldom of any service; and the frequent applications of hemlock poultices have been known to do much harm, by bringing these tumours sooner to an open cancer. The hemlock bath requires no direction. The proportions are those of the fomentation. See Wilmer's Observations on Poisonous Vegetables. Withering's Bot. Arrangement, vol. i. p. 161. Cullen's Mat. Med.

**CICUTA AQUATICA**, vel **VIROSA**. **WATER HEMLOCK**, also called *sium majus alterum angustifolium*, *sium cruce folio*. **LONG-LEAVED WATER HEMLOCK** and **COW-BANE**. It is the *cicuta virosa* Lin. Sp. Pl. 365. Dr. Withering gives the following description of it:—Rundle roundish, with many equal spokes. Rundles roundish, with many bristle shaped spokes. Empalement; general fence none. Partial fence of many leaves; little leaves, bristly, short. Cup scarcely evident. Blossom general, uniform. Florets all fertile. Individuals: petals five, egg shaped, nearly equal, bent inwards. Chives; threads five, hair like, longer than the petals. Tips simple. Pointal; seed bud beneath. Shafts two, thread shaped, longer than the petals, permanent. Summits roundish. Seed vessels none. Fruit nearly egg shaped; slightly furrowed; divisible into two. Seeds two, somewhat egg shaped; convex, and scored on one side; flat on the other. To this he adds, with rundles opposite the leaves. Leaf stalks with blunt borders; leaves with about seven pair of little leaves, which are variously divided and indented. Petals yellowish pale green. It is met with in shallow waters, and flowers in July.

It is one of the most active of the vegetable poisons. Early in the spring, when it grows in the water, cows often eat it, and are killed by it; but as the summer advances, and its smell becomes stronger, they carefully avoid it.

Mr. Wilmer observes, that the poison is of that class which produces epileptic symptoms. Wepfer notices some children, who, on eating the roots of this plant, were seized with pains of the precordia, loss of speech, abolition of the senses, and terrible convulsions; the jaws were locked, blood started from the ears, the eyes were distorted, and some of them died in half an hour. Others have observed that the old roots are a more active and sudden poison than arsenic or corrosive sublimate.

If any of this plant is taken, a quick vomit should be instantly given, after which vinegar in water should be drunk freely. See **VENENUM**.

See Lewis's Mat. Med. Lond. Med. Obs. and Inq. vol. iii. p. 229, &c. 400, &c. vol. iv. p. 104, &c. Neumann's Chemical Works. Medical Museum, vol. iii. p. 566. Withering's Botanic Arrangement, vol. i. p. 177.

**CICUTA'RIA AQUATICA**, (from *cicuta*, *hemlock*). **PALU'STRIS**. See **PHELLANDRIUM AQUATICUM**.

**CICUTA'RIA VIROSA**. See **CICUTA AQUATICA**.

**CICUTA'RIA**. See **CHÆROPHYLLUM SYLVESTRE**, and **MYRRHIS**.

**CI'DRA**. See **POMACEA**.

**CI'GNUS**. A measure so called, containing about two drachms.

**CI'LIA**, (from *cileo*, *to move about*). The extreme parts, or edges of the eye lids; they are semicircular, and cartilaginous, with hairs fixed in them, which are sometimes called *cilia*. See **TARSUS**.

**CILIA'RES**, (from *cilia*, *the eye lids*,) vel **MEIBOMII GLA'NDULÆ**; from Meibomius, the discoverer. On the inner edge of each eye lid, in the tarsus, is a row of small holes, which are the excretory ducts of what are called the *ciliary*, or *Meibomius's glands*. The glands themselves appear of a whitish colour, and are situated on the internal surface of the tarsus; their ducts are short, resembling white lines running down towards the edge of the eye lids: like the miliary ones, they secrete an unctuous matter, which prevents the attrition of the eye lids, from their frequent motion; keeps the edges soft and free from excoriation, and prevents the tears from falling down the cheeks. See **TARSUS**.

**CILIA'RE LIGAME'NTUM**, also called *processus ciliaris*. It is a range of black fibres, in the eye, circularly disposed, having their rise in the inner part of the choroides, and terminating in the prominent part of the crystalline, where the sclerotic, choroides, retina, cornea, processus ciliaris, and iris, end: they surround the crystalline humour, or rather the part where the sclerotic joins the choroides, and round the edge of the cornea they adhere firmly; at this circle, the choroides seems to change its colour and texture, appearing as a whitish kind of ring, termed *ligamentum ciliare*: here the internal lamina of the choroides dips inwards, to make what are termed the processes, which are little folds of the inner lamella of the choroides. These folds become broader until they terminate in a broad point in the crystalline humour; the whole radiated ring, made by the ciliary processes, is sometimes called *corona ciliaris*. See **CHOROIDES**.

**CILIA'RIS MUSCU'LUS**. That part of the muscle orbicularis palpebrarum which lies nearest the cilia, considered by Riolan as a distinct muscle.

**CILIA'TUS**, (from *cilium*, *the eye lash*). In botany it means having the margin guarded with a sort of bristles like the eye lashes.

**CI'LLO**. One who is affected with a perpetual trembling of the upper eye lid; from *cillendo*, being in continual motion.

**CILLO'SIS**, (from *cilium*, *the eye lid*). A trembling of the upper eye lid.

**CI'LO**, or **CI'LLO**, (from *cilium*, *the eye lid*). One whose forehead is prominent, and temples compressed, called *beetle browed*; the eye lid in these is also very protuberant.

**CI'MEX**. *Cimex domesticus*, *cimex lectularius*, (from *κειμαί*, *to inhabit*: so called because they infect houses). The **WALL-LOUSE**, or **BUG**: called also *cotula*. It is of a rhomboidal figure, a dark brown colour, and hath six legs. The skin is extremely tender, so that it bursts with the least compression, and emits an offensive smell. Six or seven are given inwardly to cure the ague, just before the fit comes on, and have the same effect with every thing nauseous and disgusting.

CIMO'LIA A'LBA, TERRA: called also *creta ful-tonica*, *terra* and *argilla candida*, *creta cimolia*. TO-BACCO PIPE CLAY.

It takes the name *cimolia* from the island Cimolus, in the Cretan sea, now called Argentiére, where it is procured. It hath nearly the same absorbent quality with the boles, and is often substituted for them. Its soft viscous quality is its only medicinal one, and in this particular it excels most of the earths of its kind. It is the *cimolite* of modern authors, of a greyish white, inclining to red, by exposure to air. It sticks to the tongue, and though difficult to break, is scratched by the nail. It becomes white in the flame of a blow pipe, and does not melt but with the assistance of a flux. Haüy, vol. iv. 446.

The *cimolia alba* of the ancients seems to have been a sort of loose marle; probably it was our fuller's earth. In Cornwall the *steatites*, a magnesian earth, is used as soap, as well as the *cimolia alba* of the ancients. It is usually marked with a seal, and called *terra sigillata alba*: the *terra samia* is only a fatter pipe clay.

CI'MOLIA PURPURE'SCENS TE'RRÆ. The *smectis* of Wallerius; *terra saponaria Anglica*, *terra fullonica*, and FULLER'S EARTH. It hath its name *smectis* from *σμηχω*, to absterge.

It is a kind of marle rather than a compact earth, and of the same qualities as bole. Indeed Wallerius has given this name to a true marle and to a steatite.

CI'NA CI'NÆ. See CORT. PERUV.

CI'NÆ, SEM. See SANTONICUM.

CI'NARA, (from *κινω*, to move, *quia movet urinam*). Some write it *cy'nara*, and derive it from *κυν*, *canis*, a dog; because the plant is sharp, like dog's teeth. The ARTICHOKE. Also called *alcocalum*, *articocalus*, *artischœus lævis*, *costus nigra*, *carduus sativus non spinosus*, *cinara hortensis*, *scolymus suttous*, *carduus domesticus capite majore*, *carduus altilis*. The species used in medicine is the *cynara scolymus* Lin. Sp. Pl. 1159.

Artichokes are so well known as not to require a description: they are natives of the southern parts of Europe, perennial, and cultivated in our kitchen gardens.

The bottoms of the heads, and the fleshy parts of the scales, are easily digested, though flatulent, and afford but little nourishment. They are preserved by drying them to a horny consistence, and are then so light, that forty scarcely weigh a pound. The leaves are bitter, and give out their bitterness with the juice, on being bruised and pressed. This juice is powerfully diuretic and useful in dropsies; it should be mixed with an equal quantity of white wine, and three or four table spoonfuls taken every night and morning. An infusion of the leaves is likewise diuretic, and may be employed with the same intention. The leaves themselves are astringent, and contain tanin. In France they have been employed instead of galls.

In England we only eat the heads, but the Germans and French eat the young stalks after boiling them.

CI'NARA SPINO'SA, called also *carduus esculentus*, vel *spinosissimus elatior*, *chardone*, *cactus*. *Cynara cardunculus* Lin. Sp. Pl. 1159. According to some authors it is a species of *carduus*. The CHARDON.

As a medicine it is similar to the artichoke. It is a

culinary plant, which is blanched like celery, and, like that, eaten raw with pepper and salt in Italy.

CI'NARA SYLVE'STRIS, also called *scolymus sylvestris*, *agriocinara*, WILD ARTICHOKE, or CARDONET. *Carlina acaulis* Lin. Sp. Pl. 1160. They grow in Italy and France, but the flowers are only used. See Dale, Ray.

CI'NARA ACAU'LIS GUMMI'FERA. See CARDUUS PINEA.

CINCHO'NA. See CORTEX PERUVIANUS.

CINCLE'SIS, or CINCLI'SMOS, (from *κινκλιζω*, to shake). They all mean a morbid nictitation, or an involuntary winking. Vogel uses the term *cinclesis*. Hippocrates means by the term a small and repeated motion.

CINERA'RIMUM, (from *cinis*, ashes). The ash hole of a furnace.

CI'NERES RU'SSICI. See CLAVELLATI CINERES.

CINERI'TIUM, (from *cinis*, ashes; because it is generally made of the ashes of vegetables or bones). See CUPELLA.

CINE'RULAM. See SPODIUM.

CINE'TUS. See DIAPHRAGMA.

CINGULA'RIA, (from *cingulum*, a girdle; because it grows in that shape). See LYCOPodium.

CI'NGULUM, (from *cingo*, to bind). A GIRDLE OR BELT. Dr. Cheyne, in his Essay on Regimen of Diet, says, "Cincture, with a broad quilted belt about the loins, to keep the bowels in their natural situations, and the chylous vessels in the best locality in flabby constitutions, weak bowels, and atrophies, is of great benefit." This belt is chiefly useful for fat persons.

CI'NGULUM MERCURIA'LE. A MERCURIAL GIRDLE, called also *cingulum sapientiæ*, and *cingulum stultitiæ*. It was an invention of Rulandus's; different directions are given for making it, but the following is one of the neatest:

Take three drachms of quicksilver; shake it with two ounces of lemon juice until the globules disappear; then separate the juice, and mix with the extinguished quicksilver half the white of an egg; gum dragon, finely powdered, a scruple; and spread the whole on a belt of flannel.

CI'NGULUM SA'NCTI JOHA'NNIS. See ARTEMISIA.

CINIFICATUM, (from *cinis* and *facio*, to turn to ashes). See CALCINATUM.

CINNABARI'NUM BA'LSAMUM, (from *cinnabaris*). CINNABAR BALSAM. The simple balsam of sulphur is a proper substitute, and nearly a similar medicine.

CINNA'BARIS, CINNABAR. Also called *cinnabar nativum*, *minium purum*, *minium Græcorum*, (*magnes epilepsiæ*, from its supposed usefulness in epilepsies,) *alzemafor*, *ammion*, *azamar*. Vitruvius calls it *anthrax*. Mineralogie de Haüy iii. 437.

Native cinnabar, a ponderous, red, sulphureous ore of quicksilver. It is found in Spain, Hungary, the East Indies, &c. The finest is brought from the East Indies. It is found sometimes in veins, occasionally in grains, or crystallized. Its crystals are tetraedrous.

Sometimes it is brought to us in a large irregular mass; at others in smaller roundish ones, smooth without, and striated within; and of a bright red colour throughout; its streak red and metallic; and its specific gravity from 5.419 to 10.1285. It is insoluble in the nitric, and soluble in the muriatic acid.

This ore consists of sulphur and quicksilver; the finer the colour, the more quicksilver it contains: with these constituents there is generally much earthy matter, from which it is easily sublimed. M. Proust, in the *Journal de Physique*, vol. liii. has shown that the mercury is in the proportion of 85 to 15 of sulphur, in 100 parts. The mercury seems, however, to be in a metallic state, since, on distilling a mixture of muriat of mercury and sulphur, the product is oxy-muriat of mercury and cinnabar. Æthiops mineral, according to Berthollet, differs only from cinnabar by its containing sulphurated hydrogen. See ARGENTUM VIVUM. See Dict. of Chemistry, Lewis's Mat. Med. Neumann's Chem. Works.

Cinnabar is a name now confined to the native and factitious sort; but formerly it was applied to dragon's blood, madder root, ceruss calcined to redness, and to some other articles.

*Artificial cinnabar, hydrargyrum sulphuratum rubrum*, is prepared by mixing purified quicksilver forty ounces, and pure sulphur eight ounces. The quicksilver must be stirred into the sulphur melted; and if the mixture takes fire, it is to be extinguished by covering the vessel. Then let the matter be reduced to powder and sublimed. Ph. Lond. 1788.

The quicksilver in the cinnabars is rendered inert by the sulphur, and of no efficacy as an internal medicine. The factitious or native cinnabar is supposed never to be active without having lost a portion of its sulphur, though it has been esteemed an useful medicine in diseases of the skin, in arthritic, rheumatic, and epileptic cases. Its chief use is for fumigating venereal ulcers; when the quicksilver is resolved into vapour, and blends in part with a volatile vitriolic acid, derived from the sulphur, forming a mercurial salt. This method is useful when a rapid effect is to be produced; but in general the salivation excited is violent and profuse, so that this remedy has been lately neglected.

If adulterated with red lead, it may be discovered by putting a little on a hot iron, for the cinnabar is all evaporated, and the lead remains.

This preparation is used by painters under the name of VERMILION; and the colour is improved by lessening the proportion of sulphur; and if a little arsenic be added in the sublimation, though the preparation is injured as a medicine, it is improved as a pigment.

An oval earthen jar is the best subliming vessel. The great art of making this cinnabar is first to manage the fire so as continually to keep the matter subliming, yet not so as to force its way through the mouth of the vessel, which is covered with an iron plate. Secondly, to put in but little at a time.

CINNABARIS GRÆCO'RUM. See SANGUIS DRACONIS.

CINNABARIS ANTI'MONII. See ANTIMONIUM.

CINNAMO'MUM, (from the Arabic term *kinamen*). Also called *cinnamum*, *canella*, *canella Zeylanica*, *cassia cinnamomea*, *cassia fistula*, *canella cuurdo*, *kurudu*; CINNAMON. The best sort of which the Arabians distinguish by the term *karfe*, and the ordinary, by *darsini*; the choicest sort by many is called *mosyllon*; the wood of the tree *xylocinnamomum*.

It is the bark of a tree of the laurel kind, growing in the island of Ceylon, freed from the outer green or greyish part, and cut into long slices, which curl up in

drying into quills or canes, the form in which it is brought to us. Cinnamon is very thin, light, and of a reddish yellow, or pale rusty iron colour, somewhat tough in breaking, and of a fibrous texture. It is the bark of the *laurus cinnamomum* Lin. Sp. Pl. 520. The CINNAMON TREE.

It is often mixed with the cassia bark; but the cassia hath a close smooth fracture; when chewed, is slimy; and is of a dark brown colour: the cinnamon is rougher to the sight and taste, having an astringency and brittleness in chewing, is of a paler brown colour, and breaks in splinters.

It is one of the most grateful aromatics, both to the palate and stomach, of a fragrant smell, moderately pungent but not fiery, sweetish to the taste, and somewhat astringent, but not in so considerable a degree as to be trusted alone. It proves of service in several kinds of alvine fluxes, and immoderate uterine discharges. The fine flavour is said to reside in the thin pellicle which lines the interior surface of the bark, and which abounds with vesicles of essential oil; the rest of the bark, while fresh, being merely astringent, receiving its flavour from the inner pellicle; accordingly the thinnest pieces are most cordial, and the thicker most astringent. Its stimulus and astringency are said to be occasionally inconvenient; but neither quality is in so great a degree as to be dangerous.

Infused in boiling water in a close vessel it yields the greatest part of its virtue. The watery decoction, after distillation, retains only the astringency, without the flavour of the cinnamon. The watery extract is similar.

Rectified and proof spirits extract its virtues better than water, even without heat; but, in distillation, they carry over very little of the flavour.

An extract made with rectified spirit of wine has all the virtue of the spice: cinnamon affords about 1-16th of its weight of extract.

The cinnamon water of the London college is prepared by adding to a pound of cinnamon as much water as is sufficient to prevent burning; after maceration for twenty-four hours, a gallon is distilled off. As the oil of cinnamon is very heavy, in time it falls to the bottom; and the water loses, with its milky appearance, its aromatic and cordial quality: sugar keeps the oil divided and suspended.

The spirituous cinnamon water, now called *spiritus cinnamomi*, SPIRIT OF CINNAMON, is directed to be prepared by adding of cinnamon a pound, of proof spirit a gallon, and as much water as is sufficient to prevent burning. A gallon is distilled. In distilling with proof spirit, that which arises first is almost flavourless; for the water, which arises after, brings the oil with it; and as the oil is dissolved by the spirit, it is limpid. As the oil of cinnamon is very heavy when cinnamon water is distilled, a low flattish still and a quick equal fire are proper. As very little of the oil rises with the spirit, the best method is first to distil the cinnamon with water only, and then to add a proper quantity of rectified spirit of wine.

The aromatic principle in cinnamon resides in the essential oil, which rises, when distilled with water, slow and with difficulty, rendering the liquor milky. When a large quantity is distilled at once, a small portion of the oil is found at the bottom of the receiver. To

obtain this oil more easily and plentifully, let the water, after it is distilled, stand in a cold place. A pound of good cinnamon affords a drachm, or a drachm and a half of oil; which, if exposed to the air, loses its virtue, without any sensible loss of its weight; so that it is not the oil which is efficacious, but the spirit in the oil. The oil of cassia bark is substituted for the oil of cinnamon; but as they are the same in their medicinal virtues, no objections can be reasonably made. The oleum canellæ albæ and the oleum caryophyllorum are mixed with the oleum cinnamomi.

Oil of cinnamon is one of the most immediate and most powerful cordials in languor, hiccoughs, and debility of every kind; it is so extremely pungent, that, on being applied to the skin, it produces an eschar; though a drop or two may be given in a draught, mixed up with a little sugar or mucilage of gum arabic.

Cinnamon, when fresh, affords a larger proportion of oil; but the Dutch extract great part of it in India, so that the oil may be most advantageously bought of them. In proportion as the oil is separated, the cinnamon loses its pungency. It is said that the Dutch obtain above an ounce of essential oil from every pound. If this oil be genuine, the point of a penknife dipped into it will smoke only when it approaches a candle. Should it soon flame, it contains rectified spirit of wine. The use of the cinnamon tree is not confined to the bark; for the leaves, root, and fruit, all yield oils of different qualities, and of considerable value. That produced from the leaves is called oil of cloves, and *oleum malá bathri*; from the bark of the root, an aromatic essential oil, or what has been called oil of camphor, and of great estimation as a medicine, is extracted, with a species of camphor which is much purer and whiter than the common kind: from the fruit is obtained a white sebaceous matter extremely fragrant, resembling the oleum nucis moschatæ per express. of a thick consistence, which in Ceylon is made into candles for the sole use of the king. It is white, and is called *cera cinnamomi*.

The *tincture of cinnamon* is thus prepared: Take of cinnamon an ounce and a half; of proof spirit a pint. Digest without heat for ten days, and strain. It contains all the cordial and restringent qualities of the cinnamon itself: if it is continued for some time daily, it warms and strengthens the stomach; but this daily use is often the parent of the most pernicious custom, dram drinking. *Hæ nugæ seria ducunt, in mela.*

Neumann, in his *Prælectiones Chemicæ*, says, that a pound of cinnamon contains near three-fourths of its quantity of an indissoluble earth, two ounces of resin, an ounce and a half of gum, and about two scruples and a half of essential oil. See Neumann's Chem. Works, Lewis's Mat. Med. and Cullen's Mat. Med.

The compound tincture of cinnamon, formerly the *tinctura aromatica*, is prepared by adding, cinnamon bruised six drachms; lesser cardamom seeds, freed from their husks, three drachms; long pepper and ginger, reduced to powder, of each two drachms; to two pints of proof spirit: after digesting for eight days it is strained. Ph. Lond. 1788.

CINNA'MOMUM SPU'RRIUM, i. e. CORT. CARYOPHYLLOIDES.

CINNUM, or CINNUS. See CYCEON.

CINZI'LLA. See ZONA.

CION, κίων, a COLUMN. The uvula is so named from its pyramidal shape. (See UVULA, HIMAS.) Hippocrates gives this name to a carunculous excrescence in the pudendum muliebre.

CIO'NIA. In Dioscorides it is the middle part of a whelk, or purple fish, near the centre of the striæ; which, being calcined, is supposed to be more caustic than the other parts.

CIO'NIS, (from κίων, the uvula). A painful thickness of the uvula.

CIRCÆ'A, (from *Circe*, the famous enchantress; on the supposition that it was used in her enchanted preparations). ENCHANTER'S NIGHTSHADE. *Circæa lute-tiana* Lin. Sp. Pl. 12. Called also *dipcæa*. Its leaves resemble those of the garden nightshade: the flowers are small and black; the seeds like those of the millet; they are inclosed in a sort of corniculated capsule: the roots are three or four spans long, white, scented, and heating. It grows on rocky ground, where it is exposed to the sun. Its virtues, if any, resemble those of the garden nightshade.

CIRCOCE'LE, (from κίρκος, *varix*, and κελή, a *tumour*). A corruption of CIRSOCELE, q. v.

CIRCULA'TIO, (from *circulo*, to compass about, moving as it were in a circle). CIRCULATION. For what is understood by it in chemistry, see CIRCULATORIUM and DIGESTIO.

In anatomy it is the circulation of any fluid through the vessels destined for its conveyance. Strictly speaking, circulation is only applied to the blood, because it moves from the heart to return to it again; but the other fluids do not return to the organ from which they were first discharged.

The honour of the discovery of the circulation is undoubtedly due to Dr. Harvey; but it has been claimed for Servetus, Columbus, and Cæsalpinus.

Servetus was an opponent of Calvin, and persecuted by him. He was a Spanish physician; but was not the author of any known medical work. In a theological tract, by way of allusion, he mentions the circulation of the blood through the lungs, rather indeed as an hypothesis than as an established fact. It is of more importance, in another view, to remark, that he considers the object of the circulation through the lungs to be the inhaling a spirit from the air, and the escape of a fuliginous vapour. He was unacquainted, however, with the structure of the heart, or the uses of the valves; and, with Galen, confines the blood to the liver and veins, while he supposes the heart and arteries filled with a spirit. Columbus, in 1569, followed him in describing this lesser circulation, and first explained the structure and use of the sigmoid and tricuspid valves; but with little consistency adopted, also, the fancies of Galen first mentioned.

Cæsalpinus published about twelve years after Columbus, viz. in about 1681; and had not the authority of Aristotle and Galen possessed his imagination so strongly as to shut out the most obvious consequences of the best established facts, the honour of the discovery must

have been his own. But his claims to genius of the highest rank are undisputed without this additional laurel. Aristotle first misled him by distinguishing two kinds of blood; one for the increase and the other for the nourishment of the body: the first he supposed to be derived from the liver, and poured into the vena cava, attracted by the heat of the heart. From the right ventricle he traces the blood, with Columbus or Servetus, to the lungs, where he supposes it to be cooled only. The blood, now become spirituous and alimentary, in successive periods, according to this system, causes, by the fermentation excited, the succession of pulsations, while the aliment destined for increase is elicited from the veins; yet in sleep this effervescing blood, he admits, is returned by the veins, the valves of which had been described by J. B. Cannanus, and, more accurately, by Fabricius ab Aquapendente.

Such were the opinions which Harvey found in the schools; and he need only have recollected that simplicity was the criterion of truth, to suppose that blood, which circulated in the night, might also circulate in the day. This was the foundation of our remark in the history of surgery (see *CHIRURGIA*), that the facts were already established, and that it required only "patient thinking" to connect them. The claim to this quality distinguished both Harvey, Newton, and Columbus; nor, if we know any thing of the human mind, does this representation diminish their credit. Peaches had for ages fallen from the tree; the structure of the valves of the heart been for years known; and the Indies long discovered by an eastern course; when the calm dispassionate examination of these three first of philosophers drew consequences which had escaped all their predecessors. They have received their reward; for they have demonstrated how high human intellect can soar: it is for their opponents to show how low it can descend.

With regard to the circulation, however, it is thus clearly described. The blood is conveyed from the left ventricle of the heart, by the aorta and its branches, to the minutest and most remote parts of the body; and then passing from the extremities of the smallest arteries into the incipient veins, whether continuous or not anatomists have not decided, circulates through them into their larger branches into the right auricle of the heart, and in succession to the right ventricle. It is forced with the fresh supplies that it receives from the chyle, passing into the subclavian vein, from thence into the pulmonary artery; and after circulating through the lungs, in its passage, is returned by the pulmonary vein into the left auricle, and thence into the left ventricle. The same round recurs until death concludes the progress.

When Harvey promulgated this doctrine is uncertain. It has been supposed, that he delivered his new system in the Lumley lectures, 1615. It is, however, singular, that a discovery so important should have passed unnoticed; though little doubt can be entertained that this important fact was established in his own mind early in the following year. This appears clearly from his *MS. De Anatomia Universa*. In the year 1619 this great discovery was promulgated; for, if we are not mistaken, in that year his *Exercitatio Anatomica de Cordis, and Sanguinis Motu*, appeared at Frankfort; a choice probably dictated by the convenience of circulation on the continent. This treatise is a masterpiece of

simple, but cogent and decisive argument. After shortly confuting the errors of his predecessors, he describes the motion of the heart as it appears in a living animal; points out the alternate dilatations and contractions of its different auricles and ventricles, and their effect as regulated by the various valves. He then shows, by calculation, that the blood flows faster into the arteries than it can be supplied by aliment imbibed by the veins; and, as the arteries can receive no supplies but from the veins, the former must be gradually more distended, or the latter more emptied, unless the veins and arteries anastomose, which was supposed less improbable, as this communication takes place in the lungs. A few simple experiments illustrate this idea, and establish it beyond contradiction.

The clamour that this publication excited was inconceivable. It was either not true, or the ancients had already taught the same. Riolan, a more respectable antagonist than the common herd, was alone honoured with an answer: and the venerable antagonist retired with some disgrace from the field, accused of cavilling, unmeaning quibbles, rash unfounded assertions, and even unfaithful experiments. The number and names of his other antagonists which lie before us would fill our page, with little advantage or satisfaction to our readers.

During the dilatation of the heart, when the blood enters the ventricles the coronary arteries receive that fluid, contrary to all the other arteries of the body, and thus supply the muscular fibres of the heart with the blood; for the passage of the blood is freer through the arteries during the heart's inflation than at the contraction, because those vessels are then less convoluted. That the heart is not the one and sole cause of circulation appears, because the arteries all perform their diastole at the same instant in healthy people. If the heart's propelling the blood was the sole cause of the circulation, the pulsation of the artery would be an undulation, and in different parts it would be perceived at different times, as the impulse at different distances of the artery from the heart would be in succession.

That some other power than the velocity of the blood dilates the capillary arteries to give passage to the globules, seems evident also from the experiments of Dr. Hales. He poured water into the aorta and other arteries of dogs; and though its force and velocity were equal to that given to the blood by the heart, yet it never passed by the anastomoses of the arteries and veins, but through the sides of the arteries; and this seems to prove that the arteries are totally stopped by the contraction of their fibres after the vital power no longer continues to act, and that the force of the heart hath not a power equal to what is required to dilate them. To this experiment indeed objections may be made; but strong arguments may be adduced to render the principal position highly probable. It is supported with great force by Dr. Whytt.

The whole arterial tube, therefore, contributes to the motion of the blood; and the heart, instead of moving a weight equal to the whole mass in this way, impels no more than about two ounces, the quantity supposed to be contained by the ventricle in each diastole. See *ANIMALIS MOTUS*, also Haller's *Physiology*.

The laws of the circulation, or the general circumstances that influence its various modifications, must detain us a

little longer. Physiologists have anxiously endeavoured to ascertain the quantity of blood thrown out by each contraction of the heart, as well as its velocity. But these circumstances are of little real importance, and we need not examine nor attempt to refute the calculations and errors. It is enough that the left ventricle contains about two ounces; and that probably somewhat less is thrown out at each contraction. Whatever the velocity may be, it is gradually diminishing; for the areas of all the branches exceed that of the aorta, and the angles must sometimes impede rectilinear motion. A proportion of the impetus is in this way lost; nor is the resistance of the coats of the arteries, or the friction, to be wholly overlooked; though the elasticity and the muscular power, as well as the mucous secretion on the internal surfaces, greatly lessen its effects.

The velocity of the blood in the arteries will be in proportion to the frequency of contraction; and this in proportion to the return of blood in the veins, which is influenced by a variety of causes, chiefly exercise and agitation of mind. The frequency of the contraction, which arises from irritability, does not increase the velocity of the blood, since, in such instances, the left ventricle contracts before it is filled, and this state is not attended with a determination to the surface. In a healthy state the arteries are always full, and consequently each impulse gives successive momenta to the whole mass: but this succession is so rapid, and the action of the arterial coats so immediate, that the pulsation, which is the consequence, is apparently synchronous over the whole body. As, however, the velocity diminishes from the causes mentioned, this pulsation must be at last imperceptible; and at some distance from the heart, and more particularly in the veins, it is of course lost. The velocity of the blood will therefore vary in proportion to the power of the heart, to the distance from it, to the causes influencing the action of the arteries, and to the direction as affected by gravity.

The quantity of blood distributed to any part of the system will differ in proportion to the action of the arteries of that part; an action increased by resistance of every kind: but the effects of that resistance, at first owing to the action of the arteries of that part, and afterwards to the general consent of every part of the circulating system, is little affected by the state of the circulation in a distant part. The contrary idea has induced the most singular and preposterous practice. It is the parent of the doctrines of *derivation* and *revulsion*, which we shall afterwards notice. Thus, if the head was affected, blood was drawn from the feet; but it will be at once obvious, that sixteen ounces of blood from a vein, if affecting one thousand six hundred arteries, will lessen the quantity of blood in each only 0.01; consequently, on the contraction of the left ventricle, only one hundredth part less of blood will be sent to the head. But if the sixteen ounces be taken from the temporal arteries, or jugular veins, the head will be depleted in the same proportion, without any diminution. It is to be regretted that this idea continues to prevail among practitioners; and we still find blisters and cataplasms applied to the legs to relieve congestions in the head or lungs.

The quantity of blood distributed to different parts varies at different periods. In the growing state, the heart evidently increases in its bulk in a less proportion than

the capacity of the arterial system. As age approaches, the number of the arteries lessens, and the proportion of the heart gains the ascendancy. In this state the venous system is proportionably fuller than the arterial. In young animals the head is large, and its vessels full. Diseases of the head, from fulness and hæmorrhages from the nose, are then common. At a subsequent period the determination is to the lungs, and soon afterwards to the genital system in both sexes; at a more advanced period to the hæmorrhoidal vessels. When the number of arteries diminishes from age, we find venous plethora in the head, with serous apoplexies and palsies; in the lungs, with humoral asthmas and catarrhus suffocativus; in the abdomen, with discharges of black bile; in the extremities, with varices.

Any general increase of the action of the arteries determines the blood rather to the surface than the internal parts; but, if checked in its determination to the surface, or irregularly accelerated or retarded, the viscera chiefly suffer. If, from the continued action of any cause, a fixed determination to any part is established, it becomes a necessary part of the constitution, and cannot without danger be altered.

The whole of the blood sent from the heart is not returned to that organ by the veins. The exhalations from the arteries into the cellular substance employ a part of it; the various secretions also greatly lessen it. The arterial system, however, always continues full, in consequence of the contractility of its muscular coat. The venous system has not this advantage, but the motion of the blood is slower in these; and, as it is kept up by the pulsation of the arteries, muscular action, &c. while advantage is taken of every action by the frequent interposition of valves, these vessels must continue full, since, from the want of any active force, a portion must be discharged into the heart, before that below can be propelled forward.

Some other circumstances respecting the circulation can only be understood when the structure of the heart is known. See Cor.

We have remarked, that there is some doubt whether arteries terminate by continuous vessels in veins: in the corpora cavernosa penis they do not, and the veins there certainly absorb the effused blood. The course of the circulation also, when minutely examined, is not regularly progressive. It sometimes is retrograde for a little way, favoured by an anastomosis, chiefly when the vessel will not admit the red globules. The veins too do not all pass immediately to the heart; for, as we have remarked, those of the abdomen unite in forming the vena portæ dispersed in the liver, apparently for the secretion of bile.

The circulation of the blood in the fœtus hath some peculiarities different from what is observed in adults. 1st, The blood does not all pass through the lungs; a very small part only takes that course each time that it returns to the heart. 2dly, The blood brought by the two venæ cavæ into the right auricle of the heart passes chiefly into the right ventricle, but not entirely; for some portion goes immediately through the foramen ovale into the left auricle, and especially that brought up by the cava inferior. Suppose, then, two-thirds of the blood passes into the right ventricle; in order to circulate through the pulmonary artery; yet all the blood that flows into it in the fœtus will not circulate through the

lungs, for a considerable part must necessarily pass by the ductus arteriosus, directly to the aorta, before it hath arrived at the lungs; so that probably not above one-third of the blood circulates through the lungs every time it is brought back to the heart. That blood which was thrown out directly from the right to the left auricle, goes thence to the left ventricle, and so on to the aorta, without touching at either the right ventricle or pulmonary artery, and consequently not arriving at the lungs. After the child is born, and a little grown up, the foramen ovale is closed up in most subjects; though, in some instances, it is found to continue more or less open during the whole life of the person.

**CIRCULATORES**, (from *circulo*, to compass about). See **AGYRTÆ**.

**CIRCULATORIUM**, (from the same). A **CIRCULATORY GLASS**. It is a vessel in which the contained liquor, when put over the fire, circulates by ascending and descending in such a manner, that the more volatile parts of the liquor, raised by the fire, not finding a passage, may always fall back again. Thus chemical circulation is only a species of digestion. Repeated distillation sometimes answers the end of circulation. See **DIGESTIO**.

**CIRCULATUM**. According to Boerhaave, the *circulatum* of Paracelsus was a liquor prepared from sea salt. Paracelsus obtained from this salt a perpetual oil, which he called *circulatum minus*, *circulatus sal minor*, *ens grimum salium*, *oleum salis*, *aqua salis*. He had also a *circulatum majus*, which he called *materia mercurii salis*, and *ignis vivens*. See Barchusen in his *Pyrosophia-Maets*, *Collectanea Chimica Leydens*, and *Blancard's Lexicon Renovatum*.

**CIRCULI I'GNEI**. See **ECLAMPSIS**.

**CIRCULUS**, (dim. of *circus*, a circle). A **CIRCLE**. Besides its proper signification, it is applied to different parts of the body; as, by Hippocrates, to the balls of the cheeks, the orbs of the eyes, or the cavities which surround the eye. *Circulus* is also the name of an iron instrument used by the chemists for cutting off a neck of glass vessels. The *circulus* is heated, then pressed close to the glass where to be divided; and when the glass is hot, the application of a blast of cold air, or a few drops of water, separates it. The *circulus* is sometimes called *abbreviatorium*.

It is also reckoned among surgical instruments, figures of which may be seen in *Scultetus's Armamentarium Chirurgicum*, tab. xxii. fig. 6, 7; tab. xliii. fig. 5.

**CIRCULUS QUADRU'PLEX**. See **CIRCUS QUADRU'PLEX**.

**CIRCULUS ARTERIO'SUS I'RIDIS**. It is composed of two arteries going round the basis of the iris. From the arteries of the external lamina are sent several ramifications to the circumference of the iris, where they produce a vascular circle, called *circulus arteriosus*. From this vascular circle pass off many smaller vessels, which form themselves into arches; and from these arches still finer vessels are sent, which probably secrete the aqueous humour.

**CIRCUMCALUA'LIS**. See **ADNATA**.

**CIRCUMCI'SIO**, (from *circumcido*, to cut about). **CIRCUMCISION**. *Albucasis* describes several methods of performing this operation; but the best is to stretch the prepuce over the glands, and make a ligature about

it, then with a razor cut of all that extends beyond. In warm countries this operation seems to be sometimes necessary, and always convenient, in point of cleanliness; for the discharge of the glandulæ odoriferæ lying under the prepuce, corrupts and becomes acrid; corrodes and inflames the glands and the prepuce.

**CIRCUMFERUS**, (from *circumfero*, to twist about). In botany it means twisting round like the tendrils of a hop round the pole.

**CIRCUMFLEXUS PALA'TI**, (from *circumflecto*, to fold about; so named from its winding position). Called also *musculus tubæ novus Valsalvæ*, *palato-pharyngæus*, *spheno-salpingo-staphylinus*, *peri-staphylinus externus*, *tensor palati*. Of this muscle Valsalva was the discoverer. It rises from the spinous process of the sphenoid bone, behind the foramen ovale, which transmits the third branch of the fifth pair of nerves from the Eustachian tube, not far from its osseous part; it then runs down along the pterygoides internus, passes over the hook of the internal plate of the pterygoid process by a round tendon, which soon spreads into a broad membrane. It is inserted into the velum pendulum palati, and the semilunar edge of the os palati, and extends as far as the suture which joins the two bones. Its use is to stretch the velum, to draw it downwards, and to a side towards the hook. It has little effect upon the tube, being chiefly connected to its osseous part. Innes.

**CIRCUMFORA'NEL**, (*quia circum fora versari soleant*, because they attended markets). See **AGYRTÆ**.

**CIRCUMGYRA'TIO**, (from *circumgyro*, to turn round). **CIRCUMGYRATION**. A turning of the limb round about in its socket.

**CIRCUMLI'TIO**, (from *circumlino*, to anoint all over,) in general, is any medicine applied by way of unction, or as a liniment; but, in a particular manner, it is appropriated to ophthalmic medicines, with which the eye lids are anointed.

**CIRCUMMOSSA'LIS**, (from *circum*, around, and *os*, a bone). See **ADNATA** and **PERIOSTEUM**.

**CIRCUMSTA'NTIÆ**, (from *circumsto*, to stand round). **CIRCUMSTANCES**. In medicine, they are whatever are not essentially necessarily connected with the principal indicant. Of this kind, in what are commonly called *res naturales*, are the condition of the patient and the part affected; the strength, age, sex, custom, and way of life; in the *præternaturales*, or the times of diseases, paroxysms, number, and symptoms. In the *non-naturales* are the air and soil. These circumstances often regulate the conduct of a physician.

**CIRCUS, QUADRU'PLEX**, from the Chaldee term *carka*, to surround,) also *circulus*. The four fold circle. It is a kind of bandage; called also *plinius laqueus*. See *Galen de Fasciis*.

**CIRRUS**, rather **CIRRHUS**, (from *κερας*, cornu, a horn; because cirri resemble the figure of horns in their spiral girations). It is one of the fulcra of plants, called also *clavicula*, *tendrils*, *capreolus*; the spiral string, by which some plants fix themselves to other bodies. They are of various textures: some of them emit a glue at their termination, by which they stick as well as cling; others have points, by which they stick into trees and walls, serving also for roots.

**CIRRI**. In *Pliny* they signify the four lesser claws of the polypus. See also **CERÆÆ**.

**CIRSIUM ARVE'NSE**, (from *κισσος*, a vine, or

swelling of a vein; which this herb was supposed to heal). See *CARDUS HÆMORRHOIDALIS*.

**CIRSOCE'LE**, (from *κίρσος*, a *varix*, and *κλην*, a *tumour*). It is also called *varicocele*, *circoccele*, *ramex varicosus*, and *hernia varicosa*.

This is an irregular, elastic tumour of the spermatic arteries and veins. Any large tumour in the abdomen, or external force pressing the veins, or a large tumour of the scrotum stretching the vessels or impeding the return of the blood, may occasion the veins of the scrotum, or the spermatic veins, to be dilated with blood; in which case, they are also here and there diversified with large and unequal knots, and the testicles hang lower than in their natural state. This disorder, however, generally depends on a relaxed state of the veins themselves.

Sometimes young men of a salacious turn, abounding with seminal fluids, are subject to this disorder; but when neither pain nor other troublesome symptoms attend, no regard need to be paid to the case, except it be to apply to matrimony for the cure. As this disorder is symptomatic, to remove the circumstances on which it depends will be its relief. It sometimes depends on the pressure of an hernial truss upon the spermatic process; and then an alteration in the bandage will probably succeed. If tumours of a scirrhus kind are the cause, and they are so situated as to admit of extirpation, they should be removed. However, when the veins have been long distended, so that their coats are become very weak, incisions may be made longitudinally into them, after which, dressing as in a common wound, a cicatrix will prevent the return of the complaint. Before incisions are made in the veins, it will be proper to try a suspensory bandage, the cold bath, the application of a solution of alum, or other astringents. Before opening the knot in these veins, it will be proper to employ evacuates, lying in an horizontal posture, by which the course of the returning blood is facilitated; the scrotum and its contents should be supported by a proper bandage, and strengthening embrocations may be applied to the part affected. See Heister's Surgery. Bell's System of Surgery, vol. i. p. 493. Pott's Works, 4to. White's Surgery, 334.

For the distinction between this complaint and bubonocoele, vide in *VERBO*.

**CIRSOI'DES**, (from *κίρσος*, *varix*, and *εἶδος*, *forma*, *likeness*; so called from its resembling a varix). It is an epithet in Rufus Ephesius for the upper part of the brain. He also applies this name to two of the four seminal vessels.

**CIR'SOS**. *Κίρσος*, (from *κερσσω*, to dilate). See *VARIX*.

**CIS'SA**. (Greek.) See *PICA*.

**CISSA'MPELOS PAREI'RA**, (from *κισσος*, *ivy*, and *αμπελος*, *the vine*). The *WILD VINE*; so called because it has leaves like ivy. See *PAIREIRA BRAVA*.

**CISSA'RUS**. See *CISTUS*.

**CISSI'NUM**, (from *κισσος*, *ivy*). The name of a plaster mentioned by P. Ægineta.

**CIST**, or **XIST**. A measure of wine containing about four pints.

**CISTE'RNA**, (from *cista*, a *cist*). A *CISTERN*. A name of the fourth ventricle of the brain, and of the concurrence of the lacteal vessels in the breasts of women who suckle.

**CI'STHORUS**, and **CISTUS**, *κίσθος*, (from the Hebrew term *kiss*). The *cistas*, or *rock rose*; also *cissarus*, *cistus creticus*, *dorycinium*. It is a shrub which grows in stony places: it is full of branches and leaves, but not tall: the leaves are round, black, and hairy. The leaves of the male cistus resemble those of the pomegranate tree, but those of the female are white. See *LADANUM*.

**CI'STUS HU'MILIS**. See *PARNASSIA*.

**CI'STUS LADANI'FERA**. See *LADANUM*.

**CI'STUS LE'DON**. See *LEDUM PALUSTRE*.

**CI'THARUS**. According to Hesychius, it signifies the breast, the side, and a species of fish.

**CITRA'GO**, **CITRA'RIA**, (from *citrus*, *the citron*; because of its smell). See *MELISSA*.

**CI'TRAS**, and **CI'TRATS**, (from *citrus*, *the citron*). **CITRATE**. Salts formed by the union of acid of lemon with different bases. The common saline draught is styled *citras potassæ*.

**CITRE'UM**, (from *citrus*). Called also *citron*, *malus medica*, *malus citria*. The *CITRON TREE*. *Citrus medica* Lin. Sp. Pl. 1100.

It was first brought from Assyria and Media into Greece, and thence into the southern parts of Europe, where it thrives, and produces perfect fruit, called *cedromela*, which is larger and less succulent than the lemon; but in all other respects the citron and lemon trees agree: the lemon is a variety only of the citrus medica.

As to its medicinal qualities, the chief differences from those of the lemon are, that the citron juice is less acid. the yellow rind is hotter, bitterish, and its flavour more volatile, so that it rises with rectified spirit of wine. The citron juice, when sweetened with sugar, is called by the Italians *aigre di cedre*.

Oils obtained from the fresh peels of the more odiferous kinds, by rolling the fruit on a plane stuck full of points, are brought from Italy, and used as perfumes; these are more grateful and less pungent than such as are drawn by distillation with water. The oil prepared either of these ways is subject to lose its flavour, and become thick and resinous in keeping; when distilled with rectified spirit of wine, and afterwards separated from the spirit by dilution with water, it retains much longer its odour, fluidity, and limpidness. See Lewis's Mat. Med.

**CITRINA'TIO**. COMPLETE DIGESTION.

**CITRI'NULA**, (a dim. of *citrus*, *a citron*; so named because its smell somewhat resembles that fruit). **SPEARWORT**. See *RANUNCULUS LONGIFOLIUS*, &c.

**CI'TRON**, and **CI'TRUS**. See *CITREUM*.

**CI'TRONELLE**. So the French name the liquor which we call *Barbadoes water*. Take the dry yellow rind of citron lb iij. of French brandy lb vi. infuse cold for a month, then distil in a sand bath, in a retort, with a receiver luted to it. When the strongest part of the spirit is drawn off, add to the remainder the pulps of the citrons; let them macerate five or six days, and distil them; add what comes over to the former strong spirit; and to this mixture as much sugar and orange flower water as is needful to render it agreeable.

**CITRU'LLUS**, called also *anguria*, *jace Brasiliensis*, *tetranguria*; the *WATER MELON*, or *CITREL*. It is the *cucurbita citrullus, foliis multipartitis* Lin. Sp. Pl. 1434. It is a gourd, called by the Greeks *αγγουρίον*.

from *αγγος*, which signifies any vessel or receptacle. This name was probably given, because, when the pulp is taken out, the shell will hold any liquor. The branches run along the ground; the fruit is very large, the rind is smooth, of a green colour, variegated with specks of a paler green, though in this it is not always the same. The pulp is grateful to the taste; the seeds are oblong, broad, rhomboidal, and blackish. The seed only is used in medicine; and is one of the four greater cold seeds, but not employed in this kingdom.

CITRUS AURANTIUM, (from *κίτρος*, *quasi κίτρος*, or *κεδρος*, from its pleasant cedar-like smell). See AURANTIA HISPALENSIS.

CITTA. (Greek.) A PIE. A voracious bird. See PICA.

CIVETA, or CIVETTA, (from the Arabic term *sebet*). See ZIBETHUM.

CLÆR. A chemical term for the BONE FLOUR, which is prepared from the bones of the fore part of the cranium of a calf, depurated from the fat by boiling, then calcined to whiteness, and levigated finely, afterwards moistened with water, and calcined again in an earthen pot closed: after cooling, it is reduced again to a subtle powder, which is sprinkled through a sieve upon earthen vessels, to prevent their contracting chinks.

CLAMOR, (from *clamo*, to cry out). An eager exaltation of the voice.

CLANGOR, *κλαγγή*. It is properly the cry of cranes, geese, &c. A shrill noise. *Clangosum de voce dicitur, quæ à gravi tono inchoata in acutum desinit.* Ainsworth.

CLARETA, (from *clareo*, to be clear). See ALBUMEN OVI.

CLARETUM, CLARET, or CLAIRET, a diminutive of *clair*, bright, transparent. By this name is generally understood an infusion of aromatic powders in wine, which is afterwardsedulcorated with sugar and honey. This sort of liquor is also called *vinum Hippocraticum*, and by the Germans *Hippocras*; because when the infusion is finished, it is strained through a filter, styled *Hippocrates's sleeve*. It is prepared of various ingredients, according to the intentions of the prescriber. *Claretum purgatorium* is mentioned by Schroeder, and is a vinous infusion of glass of antimony in cinnamon water with sugar.

Extemporaneous clarets are made by pouring into those wines a small quantity of tincture, according to the intention, made with spirit of wine, which was formerly kept under the name of the tincture of claret. Of this kind is an extemporaneous mulled wine, made with the vinous tincture of cinnamon and port wine, sweetened with fine sugar. It is also a name given by the French to such of their red wines as are not of a deep or high colour. See VINUM.

CLARIFICATIO, (from *clarifacio*, to make clean). See DEPURATIO.

CLASIS, CLASMA, (from *κλαω*, to break). See FRACTURA.

CLASPER. See CIRRHUS.

CLASSIFICATIO, and CLASSIS, (from *classes facere*, and ultimately from *κλαῖω*, to divide). Classification may perhaps scarcely at first appear to be a subject which belongs to the present work; but as we wish not to conceal that we consider the arrangement of

diseases as an object of importance, and as we have tacitly acquiesced in the propriety of the classification of plants, animals, and minerals, connected with medicine, by adopting the plans of naturalists, it is proper in this place to explain their principles.

Nature, it is said, has created only species: it is not true; for she has created only individuals. The similarity of these has occasioned the establishment of *species*; for similar individuals form a species. Individuals, differing in circumstances arising from accident; in plants and animals, from soil and climate; in diseases, from constitution; in minerals, from locality, are styled *varieties*: and these, when circumstances are changed, return to the species from which they started. These distinctions, though apparently simple and obvious, are, however, necessary; for naturalists have usually begun at the other extremity, and formed "*methods*" (see BOTANY), classes and orders, before they have established species, and, at this moment, in nosology and mineralogy, the great impediments to improvement arise from the uncertainty of what are species. Even in botany this difficulty was once so great, that more than half of Tournefort's supposed species have been found to be varieties only. Three fourths of Sauvages' species of diseases are varieties or symptoms. This latter subject we hope in future to illustrate. (See NOSOLOGY). Having shortly then pointed out the distinctions between species and varieties, as well as the means by which the former are ascertained, we shall next consider *genera*. This is the first step in arrangement; for the establishment of species consists in ascertaining identity; of genera, similarity. A striking discriminating mark, in many species, sometimes establishes a genus; at others, a general similarity. The conduct of botanists, however, has differed in this part of their labour, from the difference of their dispositions. Some naturalists, catching hastily at analogies, have included numerous species under a genus: others, more wary and exact, have retrenched them too rigorously. The latest botanists have rendered the genera more, sometimes too, numerous; but this of the two is the more venial error, since new discoveries continually enlarge them.

An *order* is an association of genera; but orders are usually too comprehensive, including too great a number of genera; and, to facilitate investigation, these are often divided into separate groups, as in mineralogy the species are sometimes again divided into sub-species. Each is a proof of imperfection in arrangement.

A *class* contains the different orders; and though, in reality, it should be the last, or nearly the last, labour, it has usually been the first; and, to make the system elegant in appearance, the classes have been few and comprehensive. The classes are connected by what in botany is styled a "*method*," which we have already mentioned. Thus, in the Linnæan system of plants, they are said to have evident or concealed fructification; and in nosology Dr. Cullen has first divided diseases into general and local, forgetting that with little change of appearance or treatment they pass insensibly into each other.

CLAUDICATIO. The name of a collyrium in P. Ægineta.

CLAUDICATIO, (from *claudico*, to halt). STAGGERING, HALTING, or LIMPING, as when one leg is

shorter, weaker, or less under the power of the will, than the other.

CLAU'STRUM, vel CLEI'THRON GU'TTURIS, (from *claudo*, and *κλειω*, to shut). The passage to the throat which lies immediately under the root of the tongue and tonsils. The term is preserved in common language, and it is styled the gleik of the throat.

CLAU'STRUM VIRGINITATIS. See HYMEN.

CLAUSURA, (from *claudo*, to shut). An imperforation of any canal or cavity in the body. Thus *clausura uteri* is a preternatural imperforation of the uterus; *clausura tubarum Fallopiarum*, a morbid imperforation of the *Fallopian tubes*, mentioned by Ruysch as one cause of infecundity.

CLAVA RUGOSA. See CALAMUS AROMATICUS.

CLAVA'TA. The name of a suture. See SUTURA.

CLAVA'TIO, (from *clava*, a club). See GOMPHOMA.

CLAVA'TUS, (from *clavis*, a nail). In botany it means shaped like a nail.

CLAVELLA'TI CINERES, (from *clavus*, a wedge; so called from the little wedges or billets into which the wood was cut to make them). Also called *alumen catinum*, *soda*, *sal alkali fixum*, *cineres Russici*, *kali*, *potassa*, *gastrinum*, POTASH, and PEARLASH.

The ancients call the ashes of burnt wood *lix*, from whence the modern appellation *lixiva*: the moderns call them also *cineres clavellati*. The English name *potash*, is from the pots in which the *lixivium* was boiled.

Potashes are made in most countries that abound with the hard kind of wood; particularly the north of Europe and America, from which last the best is brought to us; produced from the ashes of vegetable substances, by dissolving their salt in water, decanting the clear solution, and evaporating it to dryness.

Oak, ash, and other trees that shed their leaves in autumn, are proper, and the smaller shrubs, commonly called underwood; but evergreens, as the pine, cypress, &c. yield very little salt. Fern, bean straw, and the greater number of annual plants, afford a large quantity of salt; dead trees seldom afford an alkali.

The timber may be cut down at any season of the year, but should be burnt as soon as possible. Pieces of eight or ten feet long should be laid in piles, filling the interstices with the chips and smaller wood; and the fire kindled at both ends. As soon as the pile is burnt down, rake such ashes as lie thin on the outside, a little towards the middle: add no fresh fuel, nor stir the ashes till you can bear your hand in them. When placed in a shade on a plank floor, they must be wetted until brought nearly to the consistence of mortar in the first mixture of lime and sand, or so as to stick together; then rammed in a heap, in which they must continue not less than twenty days, though they may remain many months. This is called *wood ash*.

Kilns are also made for the more advantageous burning of wood into ashes.

Wood ashes, put into vessels with latticed bottoms, covered with clean straw, are to be firmly pressed together; their surface covered, four or five inches deep, with soft water, and as it subsides more added. A receiver is then placed underneath to receive the solution, and water continually added until the ley is very weak. The weak ley is strengthened by again filtering through

fresh ashes, and the whole conveyed into a pan to be evaporated to a dryness: the produce is called *potash*.

The ley of wood ashes, made strong enough to bear an egg, is boiled briskly, until a pellicle appears on the surface, then gently boiled until it thickens, and continued just bubbling until it is very hard. In that state it is taken out in pieces, which are cut out with a cold chisel, and spread on the floor of a furnace, so contrived that the salt may be just covered with the flame: if it is thus continued until it begins to look fair, and incline to look red, afterwards kept red hot, and turned occasionally, until it is of a pearl colour, it is called *pearlash*. When this pearlash is cold enough to handle, that which is imperfectly calcined, with such as falls into powder, must be replaced in a caldron, with fresh ley. From contact with some inflammable matter, or calcining with too much heat, it hath sometimes a blue colour, but it should be of a pearl colour.

Potash is said to be a creature of the fire. In some parts of Germany it is prepared from the same wood of which charcoal is made. A number of tubes, made of copper, or of iron, are so disposed in the pile of wood intended to be burnt into charcoal, that the water, acid, and oil, which are obtained in ordinary distillations, shall, when separated from the wood by fire, pass through these tubes into buckets placed to receive them. The oil is next to be separated from the acid liquor, which is then to be boiled in copper or iron vessels, and the residuum dried and calcined. By this calcination, the acid is decomposed and the alkali remains. These and many similar facts show that the alkali is a production of fire.

Pearlash is entirely soluble in water, and is, in all respects, the same as the fixed alkaline salt. See ALKALI.

Potash often, though carefully prepared, contains some portion of earth and a neutral salt, which is either a vitriolated tartar or sea salt. The earth is separable by dissolving the salt in water. The neutral salt dissolves with difficulty, and so may easily be separated by solution in cold water, which readily dissolves the alkaline salt, but leaves the neutral unaffected. The sea salt discovers itself by decrepitating, if laid on red hot iron; and is separated by dissolving one part of potash in two parts of water, for in this the sea salt will not dissolve.

Potash is met with of various colours; but when good, if it is exposed to the air, it first grows clammy, then runs to an oily liquid, which, when dried, leaves an impalpable powder of a whitish colour. It hath but little smell, and is of a pungent, urinous taste; does not crumble in solution, but dissolves gradually; it ferments with acid, and it unites, when pure, with oil.

As a medicine, the virtues of the alkaline salt of potash are the same as those of any other vegetable fixed alkaline salt.

See ALKALI. Neumann's Chem. Works. Dict. of Chemistry, 4to.

CLAVI SILIGINIS. See SECALE.

CLAVICULA. See CLAVICULUS.

CLAVICULÆ, and CLAVES. In anatomy, the clavicles, (from *clavis*, a little key). So the collar bone is called, from its likeness to an ancient key, called also *furcula*, sometimes *clidion*; *clavis*.

Each clavicle resembles the Italian letter *f*: they bend forwards near the sternum, and backwards near

the scapula. They are more straight in women than in men. They are placed almost horizontally, between the sternum and acromion, and are connected to the sternum by the articulation called *arthodia*. At their extremities, next the sternum, is a ligament, which runs across to the other clavicle, and it is connected to the first rib likewise by a ligament. These bones, by keeping the scapulæ in their proper situation, serve for the more free and easy motion of the arms. The clavicles in infants are perfect bones without any epiphyses.

CLAVICULUS, vel CLAVICULA. See CIRRIUS.

CLAVUS, (from *claudo*, to shut). A NAIL or BUTTON. An instrument in surgery mentioned by Amatus Lusitanus, to be introduced into the ulcerated palate, for the better articulation of the voice. Sometimes this word signifies indurated tubercles of the womb, and are distinguished by a similar appellation.

CLAVUS, a corn, called also *spinæ pedum*, *calli*, *condylomata*, and *tyllomata*. Dr. Cullen defines a corn to be a lamellated hard thickening of the cuticle. He ranks it as a genus of disease in the class *locales*, and order *tumores*.

Corns are a sort of horny excrescence growing on the feet and toes, sometimes on the hands of labouring people. These callosities resemble an inverted wart, and are seated in the cutis and cuticle, arising chiefly from pressure and irritation, and are excessively painful when rooted near a nerve. The easiest and best method of cure, is to take off all uneasy pressure, and apply a piece of plaster, spread with soap, or plaster of litharge, with some opium, little more than the size of the corn, which may be closed on the part for four or five days together, to render its surface soft. That part which appears sodden must be pared away, but by no means so low as to touch the cutis vera; after which the plaster is to be renewed, and the whole process may be repeated in five or six days, till the corn appears likely to separate with its root, or waste away. Soaking the part in bran and warm water is very useful previous to each cutting. Hog's gall dried in the bladder, spread thin upon a rag and applied to the corn only, has often proved efficacious: it is apt to inflame the part a little, but the corn generally withers after a few applications of this kind, and is wholly separated. See White's Surgery; also Bell's Surgery, vol. v. p. 539. See SPINÆ PEDUM.

CLAVUS HYSTERICUS, (so called from *clavus*, a nail; as the sensation resembles the driving a nail into the head). A symptom attending some cases of hysteria, which is thus described by Sydenham: "Hysterics sometimes attack the external parts of the head, between the cranium and the pericranium, occasioning violent pain, which continues fixed in one place, not exceeding the breadth of one's thumb; and it is also accompanied with enormous vomitings." (See CEPHALALGIA.) Such again attend a venereal caries, or an exostosis of some bone of the cranium.

CLAVUS OCULORUM. See STAPHYLOMA.

CLEI'DION, vel CLIDION. The epithet of a pastil described by Galen and P. Ægineta; and it is the name also of an epithem, described by Ætius. Sometimes it is synonymous with claviculæ.

CLEIDOMASTOIDE'US, (from *κλειδειον*, the clavicle, and *μαστοιδεος*, the mastoideus muscle: so called from its origin and insertion). See CLINOMASTOIDEUS.

CLEISA'GRA, (from *χλεις*, the clavicle, and *αγρα*, a pain). See ARTHRITIS.

CLEI'THRON. See CLAUSTRUM.

CLE'MA, (from *κλαω*, to break; so named from its fragility). A twig or tendril of a plant.

CLE'MATIS, (from *κνημα*, a tendril). See ATRAGENE and VINCA PERVINCA.

CLEMA'TIS RE'CTA. See FLAMMULA JOVIS.

CLEMATIS PERUVIA'NA. See BEXUGO.

CLEO'NIS COLLY'RUM. The name of a collyrium described by Celsus.

CLEO'NIS GLU'TEN. It is mentioned by Oribasius, lib. iv. and recommended for restraining fluxes: it consists of terra Samia, myrrh, grains of frankincense, of each equal parts; the white of egg, a sufficient quantity; spread on linen cloth, to be applied to the temples and forehead.

CLE'PSYDRA, (from *κλεπω*, to conceal, and *ιδωρ*, water). Properly an instrument to measure time by the dropping of water through a hole from one vessel to another; but it is used to express a chemical vessel perforated in the same manner. It is also an instrument mentioned by Paracelsus, contrived to convey suffumigations to the uterus.

CLI'BANUS, (quasi *καλαβανος*, from *καλυπτω*, to conceal). A little portable oven.

CLIFTON WATER. This well lies a mile from Deddington in Oxfordshire. It is a weaker water of the same sort with TILBURY, which see.

CLIMACTERICUS A'NNUS, (from *κλιμαζω*, to proceed gradually, as upon (*κλιμήν*), a ladder. The CLIMACTERIC YEAR. Every seventh year is usually styled a *climacteric*; but others reckon only those years that are produced by multiplying seven by odd numbers, viz. 3, 5, 7, 9, to be such. These years they say, bring with them some remarkable changes with respect to health, life, or fortune. The grand climacteric is the sixty-third year; some add to this the eighty-first year. The other remarkable ones are the seventh, twenty-first, forty-ninth, and fifty-sixth. The credit of climacteric years depends on Pythagoras's doctrine of numbers, and seven times nine (63) is the grand climacteric, since it is the peculiar number, seven, multiplied by the perfect number. Nine is the perfect number as the square of 3, which is perfect, because it is the only number made up of its parts one and two. Such were once the trifles dignified by the name of science!

CLIMATE. The term is employed by geographers, who divide the globe into parallel bands or zones of a determined breadth. By physicians it implies different regions either of more steady or more temperate warmth, more or less dry or damp.

Each state of climate may be adapted to different situations and constitutions; but, in this article, we must confine ourselves to more general remarks. Climates, as distinguished geographically, can form no part of our present subject, since we may freeze within the tropics, for even there we find regions of perpetual snow, and be relaxed by the short, though warm and humid atmosphere within the arctic circle, during its short but unremitting summer heat. In general, the interior of islands or continents offers the highest mountains, consequently the coldest situations; and these are usually, from causes unnecessary to explain in this place, gene-

rally much nearer the western than the eastern coasts. In cold climates, the body is robust, and the constitutions subject to inflammatory diseases: in these regions the invalid seeks the bracing and elastic breezes; but he must inhale them with caution; they may prove too astringent; the excitability may be accumulated in a noxious degree; and an accidental cold induce the most dangerous inflammatory diseases, more imminently dangerous as the constitution cannot bear to be depressed, since the former debility may be rapidly induced. The invalid should therefore proceed with caution, and mount the lesser heights before he ascends the Alpine mountains. The hills of Devonshire may prepare him for the mountains of Wales, and these again for the Highlands of Scotland. It is an advantage that in these situations there are numerous shelters from the eastern blasts, which are proverbially baleful.

In every country the climate near the sea is mild and moist, if we except the eastern shore of this island during the spring and early summer months. The coasts have been consequently recommended to consumptive patients, though not always with the expected advantages. Yet the air is more temperate in winter, and the heat more tolerable in summer; and in situations not exposed to the east, it would appear, *à priori*, a situation truly desirable. Dr. Rush has suggested that disadvantages may arise from the mixture of sea and land air; but until these have been found to differ, we may neglect the distinction as an unnecessary refinement. It is probable that the air is of a lower quality, that is, contains a less proportion of oxygen; but this state of the air is certainly beneficial to hectic: and, as we have hinted, if Bristol is ever advantageous, it must be in the lower situations. By a refinement, not unlike Dr. Rush's, it has been supposed that sea coasts, where no river conveys its water to the ocean, are preferable to the large estuaries. If the mixture of water and dry air is not injurious, we cannot suppose that this idea is well founded; on the contrary, where no river leaves an opening for free ventilation, storms most tremendous occasionally burst from the mountains with the most piercing coldness. This happens in many of the boasted retreats on the northern side of the Mediterranean.

In general, as we have said, we must not look for heat or cold by the measure of the latitude, but by contemplating the situation; and we can only look for a steady even temperature where the ventilation from land to sea, or the contrary, is free from obstacles. In the lower (or comparatively the lower) regions, surrounded with hills, we shall chiefly find damp situations, air of a lower quality, and a steady temperature, though occasionally interrupted by storms. Such spots are seldom unhealthy, and the asthmatic patient breathes in them with more freedom. Such is the famous valley of Cashmere; and such spots abound on the Alps, particularly in the once happy country of Switzerland. They may be sought for as remedies; but confinement in them, without change, predisposes to diseases, arising from languor and diminished irritability.

The famous resorts of invalids were Lisbon, Madeira, and the south of France. To Lisbon there seems little objection, but that the temperature is not steady, and it is occasionally subject to piercing colds. Madeira has the inconveniences attributed to those coasts not ventilated by large rivers; and the most favourite spots in

the south of France are equally subject to sudden and violent storms. When a change of climate is requisite, every advantage apparently may be gained by different situations in our own island, with the additional one of customs, language, &c. familiar to the patient. Illness, in the best regulated minds, occasions peevishness, at least irritability; and the want of the accustomed indulgences seldom fails, even though in trifles, to occasion fretfulness, which astonishes the attendants, and indeed the patient himself on recovery.

The French physicians have set an example well worthy of our imitation, viz. the publication of a medical topography of different situations. Such accounts, including the temperature, the state of the air, the rains, and prevailing winds and diseases, would be highly valuable if executed without prejudices. Our "Guides to watering places" are unfortunately dictated by the most interested motives: every advantage is magnified, every inconvenience concealed. Such topographies should be executed by medical visitants, could they be candid; and not, like Smollet, view every thing with a prejudiced eye, and a distempered imagination.

CLIMAX, (from *κλιμαξω*, to proceed). Also called *scala sacra*. A name given by the ancients to some antidotes, the ingredients in which gradually diminished in quantity, e. g. Chamædryos  $\frac{z}{2}$  iij. centaury  $\frac{z}{2}$  ij. hyperici  $\frac{z}{2}$  i. See PULVIS AD RHEUMATISMUM, under CHAMÆDRYS.

CLIMIA. See CADMIA.

CLINICUS, (from *κλινη*, a bed, also *cataclines*). CLINICAL. It is applied to patients who keep their beds. Hence a clinical physician is one who attends the sick; and clinical lectures are those in part, at least, delivered at the bed side on the cases of the patient.

CLINOIDES. The four small processes of the os sphenoides, which form the *sella turcica*, (from *ειδος*, resemblance, and *κλινη*, a bed).

CLINO-MASTOIDE'US, for CLEIDOMASTOI'DEUS. See MASTOIDEUS MUSCULUS.

CLINO'PETES, (from *κλινη*, a bed, and *πeto*, to seek). A person who, on account of great weakness, or any disorder, is obliged to lie in bed, or on a bed.

CLINOPO'DIUM, (from *κλινη*, a bed, and *πους*, a foot; so called because it has leaves like a bed's foot). See MARUM.

CLINOPODIUM MAJUS ACINOS. See BASILICUM.

CLISSUS, is a chemical technical term, and denotes mineral compounded spirits. But antimony is considered as the basis clyssi. A spirit of antimony is called *clyssus*.

CLITO'RIDIS FLOS TERNATE'NSIBUS. A beautiful flower growing in the island of Ternate. The inhabitants boil and eat it; but no medical virtues are attributed to it.

CLITO'RIDIS MU'SCULUS. Innes calls it *erector clitoridis*, and describes it as arising from the crus of the os ischium, internally covering in its ascent the crus of the clitoris, as far up as the os pubis. It is inserted into the upper part of the crus and body of the clitoris. Its use is to draw the clitoris downwards and backwards, and may serve to make the body of the clitoris more tense, by squeezing the blood into it from its crus.

CLIT'ORIS, (from *κλειω*, to inclose, or hide, because in its natural state it is closed in the vagina,) called also

*clitrum Veneris, columella, dulcedo Veneris, epideris, hyphodermis, myrton.* It is a part of the external pudendum situated at the angle which the nymphæ form with each other. Within the labia externa, at the upper angle, we observe the prominent extremity of the clitoris, which is covered with a preputium similar to that of the penis. It is very vascular and villous, to occasion a greater irritation in coitu. The clitoris is, in many respects, analogous to the penis; the two crura clitoridis, which are two spongy bodies, and form the clitoris by their union, arise from the ischium, and, running along the lower edge of the os pubis and the os ischium, unite, to form the corpora cavernosa of the clitoris. It is furnished with two erector muscles, whose origin and insertion are the same as in the penis; but though the clitoris has a glans, there is no corpus spongiosum urethræ; its trunk is sustained by a suspensory ligament, fixed in the symphysis of the ossa pubis. Like the penis, it has an erection, and it is thought to be the principal seat of venereal pleasure.

The clitoris is of different sizes in different women, but, in general, it is small, and covered with the labia; when preternaturally enlarged, it constitutes an hermaphrodite.

When the clitoris is too large, it is styled *cercosis*, and may be so extirpated as to remove the unnecessary part; but this requires much care, for if too large a portion is extirpated, the patient is subjected to an involuntary discharge of urine.

**CLITORISMUS.** A morbid enlargement or swelling of the clitoris.

**CLOACA**, (quasi colluaca, from *colluo*, to cleanse). A REPOSITORY OF FILTH. In comparative anatomy, it imports the canal in birds through which the egg descends from the ovary. It is remarkable, that the part which is next the ovary is jagged like the morsus diaboli, and fluctuates in the abdomen without any attachment to the ovary. It must, therefore, like the fimbriæ of the Fallopian tube, be erected to grasp the ovum.

**CLOATHING.** See COOPERTIO.

**CLO'NICUS**, (from *κλονειν*, to agitate). See CLONOS.

**CLONOIDES**, (from the same). An epithet for a sort of pulse which is vehement and large, at the same time unequal in one and the same stroke.

**CLO'NOS**, (from the same). *Κλονος*, also *clonicus*. Any tumultuary, inordinate, interrupted motion. It is applied to the epileptic and convulsive motions. See SPASMUS CLONICUS.

**CLO'US.** (French). See CARYOPHILLUS AROMATICUS.

**CLU'NES**, (from *κλυω*, to cleanse, because they are the parts through which the alvine fæces are ejected). The BUTTOCKS; called also *epheidsanæ pygæ*: the two posterior and lower parts of the abdomen are separated by a fossa, which leads to the anus: each buttock is terminated downwards by a large fold, which distinguishes it from the rest of the thigh. They consist of skin, fat, and muscles, principally of the glutæi.

**CLUNE'SIA**, (from *κλυνες*, the buttocks). See PROCTALGIA.

**CLUPEA**, (from *clypeus*, a shield; so called from its shape). See ALOSA.

**CLUS.** et **CLUS. HIST.** An abbreviation of Caroli Clusii rariorum Plantarum Historia.

**CLUS. HISP.** An abbreviation of Caroli Clusii rariorum aliquot stirpium per Hispanias observatorum Historia.

**CLUS. CUR. POST.** An abbreviation of Caroli Clusii Curæ Posteriores.

**CLUSIA.** *Flava* Lin. Sp. Pl. 1495. A tree in Jamaica that produces a kind of turpentine called *hog's gum*.

**CLUTTO'NI DOM. SPI'RITUS FEBRIFUGUS.** See FEBRIFUGUS SPIRITUS, &c.

**CLY'DON**, (from *κλυζω*, to cleanse). A fluctuation and flatulency in the stomach and intestines.

**CLY'MA**, (from *κλυζω*, to cleanse). The fæces of silver and gold, which have been cleansed by washing.

**CLYME'NUM ITALO'RUM**, (from *Clymenes*, who first used it). See ANDROSÆMUM.

**CLYPEA'LIS CARTILA'GO**, (from its resemblance to a shield, *clypeus*). See ASPERA ARTERIA.

**CLY'PEUS**, a shield. It is supposed to be an instrument used in the ancient baths to increase or diminish their heat, by admitting or excluding air; so called from its resemblance.

**CLY'SMA**, (from *κλυζω*, to wash out, a clyster). See ENEMA.

**CLYSSIFO'RMIS DISTILLA'TIO**, (from *clissus* and *forma*, a likeness). A distillation of such substances as are subject to take fire and fulminate by a tubulated retort.

**CLY'SSUS.** *Clissus* vel *clistus*, (from *κλυζω*, to wash). Among the ancient chemists, this word imported an extract prepared of various substances mixed together. Among the moderns, it signifies a mixture, containing the various productions of one substance united with each other; *e. g.* when the distilled water, the spirit, the oil, the tincture, and the salt of wormwood, are so blended, that the mixture is possessed of all the united virtues of the simple, from which these preparations are obtained. Clyssuses were formerly prepared from the vapours of different matters joined with nitre, several instances of which may be seen in the Dictionary of Chemistry; and as their virtues merit not the trouble of preparing them, the curious are referred to that work.

**CLY'SSUS ANTIMO'NIJ, CLY'SSUS MINERA'LIS.** It is obtained by deflagrating a mixture of antimony, nitre, and sulphur, in a red hot retort, fixed to a receiver, in which is some water. But as it is only a weak spirit of sulphur, it is not worth the labour of preparing. It is recommended as an antiseptic, and as useful in early stages of hectics. See Dict. of Chemistry, and Neumann's Chemical Works.

**CNA'PHOS.** See HIPPOPHÆS.

**CNE'CUS**, (from *κναω*, to scratch or rasp). See CARTHAMUS; also the seeds of the carthamus.

**CNEMI'U.** Any part connected with the tibia. Galen.

**CNEMODACTYLÆ'US**, (from *κνημιον*, the tibia, and *δακτυλος*, the toe; so named from its origin and insertion). See EXTENSOR DIGITORUM LONGUS.

**CNEO'RON.** See THYMALÆA.

**CNE'SIS, CNE'SMOS**, *Κνησις*, the same as *cnismos*, and *cnyma*, (from *κναω*, to scratch). That eager scratching observed in brutes; but it more generally means the itching itself.

**CNE'STON**, (from the same). It is a species of thymalæa; a *rasp*, which is also called *cnester*, and particularly a rasp for scraping cheese.

CNICELÆ'ON, (from *κνικῶν*, *cnicus*, and *ελαιον*, *oil*). Oil made of the seed of *cnicus*. Its virtues are the same with those of the *oleum ricini*, but in an inferior degree.

CNI'CION. A name of the trifolium.

CNI'CUS, (from *κνῶν*, *to scratch*). The heads are surrounded with a crown, formed of a complication of numerous leaves. Many of the species of the former genus are removed to that of *carduus* and *atractylis*, q. v.

That used as a purge by Hippocrates is supposed to be the *carthamus*; but modern botanists exclude it from the species of this plant.

CNI'CUS A'LBIS MA'CULIS NOTA'TUS. See *CARDUUS LACTEUS SYRIACUS*.

CNI'CUS SYLVE'STRIS. See *CARDUUS BENEDICTUS*.

CNI'DE, (from *κνῶν*, *to scratch*). See *URTICA*.

CNIDELÆ'ON, (from *κνιδῆ*, *the nettle*, and *ελαιον*, *oleum*). Oil made of the *cnidia grana*.

CNI'DIA CO'C'CUS. See *THYMALÆA*.

CNI'DIA GRA'NA. CNIDIAN BERRIES; called *Ætalion*, *cocca cnidia*, *coccalos*. *Daphne gridium* Lin. Sp. Pl. 511. These berries are highly acrid and poisonous.

CNIDO'SIS, (from *κνιδῆ*, *nettle*). An itching and stimulating sensation, such as is excited by the nettle.

CNIPO'TES, (from the same). IREHING. It sometimes signifies a dry ophthalmia.

CNI'SMOS. See *CNESIS*.

CNISSORE'GMIA, (from *κνισσα*, *a nidorous smell*, and *ερευνῆ*, *an eructation*). A nidorous eructation.

CNY'MA, (from *κνῶν*, *to scrape or grate*). In Hippocrates it signifies a rasure, puncture, or vellication; also the same as *cnesmos*. See *CNESIS*.

COAACHI'RA INDO'RUM. See *INDICUM*.

COA'CUS. An epithet of a treatise of Hippocrates, called *Coacæ Prænotiones*, from *Cos*, his birth-place.

COADUNA'TOS, (from *coadunatos*, *united*). In botany it means united together in some expressed manner, as *coadunata folia*, leaves joined together at the base.

COAGULA'NTIA, (from *coagulo*, *to incassate or curdle*). In general such bodies as coagulate fluids; but in medicine it signifies more particularly such remedies or poisons as coagulate the blood and juices flowing from it.

Though poisons were generally accused of coagulating the fluids, yet various other substances were employed for this purpose; and, at the present moment, spermaceti is sometimes given after lying-in, to prevent the excessive lochial discharge, and occasionally as a check to the hæmorrhages from the lungs. In the humoral pathology the class of coagulants are still numerous, and with those who retain the theory of preternatural tenuity or lentor, they must be still cherished as remedies, or dreaded as injurious. We see no instance, however, of coagulation of the vital fluids, but in cases of polypi in the heart or larger arteries; and these concretions are rather owing to occasional stagnations of the circulation from faintings, or similar temporary causes of suspended circulation, than any fault in the fluids. Some effects formerly attributed to coagulation, we now know to be the effect only of adhesive inflammation. Externally, these are undoubtedly coagulants; for whatever favours the concretion of the blood

flowing from a wound may be styled such. Of this kind are lint, especially when mixed with flour, spiders' webs, sometimes the white of an egg, or similar applications, which have been styled styptics. Internally we find an effect from one medicine that may be supposed to resemble it, viz. that of gum arabic, which, when used in large quantities, we think has sometimes lessened the flow of urine. Authors, however, who claim some credit, have arranged under this head the *consolida*, *pulmonaria*, *aloes*, *gum benjamin*, the *balsams*, *spirit of wine*, *sarcocolla*, *lapis hybernicus*, the leaves of the *elm*, *hypericum*, and *caprifolium*, some of which certainly act as styptics when applied externally.

COAGULA'TIO (from the same). COAGULATION is when a fluid, or some part of it, is rendered more or less solid. This is variously effected, and from the different methods, as well as means, the appellations vary.

Heat and cold are the two principal natural agents for coagulating fluids. When heat is used by art, its effect is called *coagulatio per separationem*. When cold is thus made use of, its effect is called *coagulatio per comprehensionem*; implying that no part of the fluid is lost, but the whole brought into a solid state.

Different means coagulate different matters: thus heat coagulates salts by dissipating their moisture; cold coagulates water by freezing it; water coagulates camphor when dissolved in spirit of wine, by uniting with the spirit and rendering it a less perfect menstruum for the camphor; spirit of wine, if pure, coagulates the white of egg and other matters; and motion coagulates milk into butter, by uniting the particles of oil.

The *coagulatio-continua* is produced either by im-pastation, that is, when powders, &c. are mixed with the fluid, or by condensation, that is, when coldness is applied to water so as to congeal it.

The *coagulatio-partis* is when one substance so adheres to another as to form a more solid body; for example, dry things with moist, oil with water, &c.

The *coagulatio-totius* is preternatural when heterogeneous matter is united; and natural, when homogeneous fluids are coagulated by way of generation.

Such are the logical distinctions of the Stahlans; but it is necessary to be more chemically accurate. Coagulation consists chiefly in precipitation, when the attraction of the fluid to the solid which keeps the latter suspended is weakened. Coagulations by heat are sometimes owing to evaporation, but more often to a chemical change, as in an instance soon to be mentioned. In many instances of apparent complete coagulation, the fluid is only entangled between the spiculæ of the crystals; and this is the case with the coagulation from cold or rapid crystallization. Sometimes it is occasioned by a chemical change. Albumen, for instance, when coagulated, is not again soluble in the same fluids as before; and butter will not again become milk with the albumen and whey. There are various instances of increased density, occasioned by different additions, which are not readily explained. The thickening of leather by astringent substances was one of these; but we now know it to proceed from precipitation of gelatine. The use of alum by the soap boilers, and in the coagulation of curd to produce whey, is not yet understood.

COA'GULUM, (from the same). Curdled concretions, formed by the mixture of two liquors, are thus

called; such, for instance, as the curd for cheese, separated from the serous part of milk, by means of rennet infused in warm water. Rennet, or runnet, is the stomach of a young sucking animal, and curdles milk without any previous preparation. The common method is, to take the calf's stomach, clean it well, salt and hang it up in brown paper: when this is used, the salt is washed off, a piece is macerated in a little water during the night, and in the morning the infusion is poured into the milk to curdle it. This property of the stomach has been attributed to the remains of the food, or to its acid; but the stomach retains its power when nicely cleaned, and no acid can be discovered in it by the most delicate taste. The whole stomach produces this singular change, and it is undoubtedly a chemical one. Some other substances, not acid, are said to produce the same effect; and Spallanzani mentions his having found similar changes from infusions of the liver of the gallinaceous tribe, particularly turkeys.

COAGULUM ALUMINIS, called also *cataplasma aluminis*. In ophthalmia it is found very serviceable, particularly in that species called purulent, applied between two pieces of fine soft linen rag. It is also said to be very effectual as a remedy for chilblains. See also ALUMEN.

COALESCE'NTIA, (from *coalesco*, to grow together). COALESCENCE. The union or growing together of two bodies, or two parts which before were separate.

COALTER'NÆ FE'BRES, (from *con*, and *alternus*, alternate). Fevers mentioned by Belini. He describes them as two fevers affecting the same patient, and the paroxysm of one approaching as that of the other subsides. It is a rare occurrence, but by no means imaginary.

COARCTA'TIO, (from *coarcto*, to straiten). COARCTATION. A contraction of the diameters of the vessels. A coarctation of the pulse is a diminution of the capacity of the arteries, from the increased tone of the muscular coat.

COARCTA'TUS, (from the same). In botany it means pressed together very closely.

COARCTICULA'TIO, (from *con*, and *articulatio*). See ARTICULATION.

COA'TLIS. See BEN.

COBAL'TUM, *kobalt*, (Germ.) called also *cadmia metallica*. COBALT. It is a ponderous hard metallic substance, found in some parts of Asia, now chiefly dug up in Saxony, but also met with in England. The best way of distinguishing it from other minerals is to melt it with glass, for it imparts a sapphire blue colour: from it the greatest quantity of arsenic is obtained that is used all over Europe.

When dug, it is mixed with various other substances; it is then broken into small pieces, and calcined in a reverberatory furnace, so formed as that the flame of the fire may pass over the calcining matter, and keep it ignited: the flame, in passing over the cobalt, carries off a copious fume, which is conveyed from the top of the furnace into a large long winding wooden chimney, to the inside of which the fumes adhering in the form of a white soot, are at proper intervals swept down, and when melted form the white arsenic. The cobalt is next repeatedly calcined, and then finely ground with two or three times its weight of powdered flint. From this mixture, when melted, zaffer is produced.

If two parts of calcined cobalt, one part of potash, and three parts of common sand, are melted together, a vitreous opaque, bluish mass is formed, which, when ground to powder, is called *smalt*, or *encaustum ceruleum*, *powder blue*.

On the outside of the mines where cobalt is found, there is a mineral of the colour of streaked roses, called the *flower of cobalt*.

The chief use of this mineral is for obtaining arsenic, and the reguline part is the blue made use of for colouring glass or china. See Lewis's Mat. Med. Dictionary of Chemistry, and Neumann's Chem. Works.

COBA'STOLI. ASHES.

CO'BBAN. A small tree resembling the peach tree. It grows in Sumatra: the fruit quenches thirst, and the kernel affords an oil by expression, which is externally used against pains. Raii Hist.

COBHAM WATERS. These arise from a spring which lies a mile south from Church Cobham, about twenty-four miles from London. It is considered as one of the weaker saline purging waters. See AQUÆ CATHARTICÆ AMARÆ.

CO'BRA DE CAPE'LLO, (from *cobra*, the head, or covering; Spanish). A venomous serpent, which is also called *serpens Indicus coronatus*, *vipera Indica vittata*, *vipera fileata*. The RATTLE SNAKE. *Crotatus horridus* Lin. Syst. Nat. (Gmelin) 1080. The part in use is a stone taken out of its head, whence its name of *cobra*; called *pedro del cobra*, and by mistake *pedra di cobra*: it is of an oval figure, plain on the outside, and gibbous on the other, of a brown colour, shining, with pores interspersed. It is said to be an antidote to the poison of venomous animals; but neither this quality nor the truth of its being a natural production is ascertained; for the Pierres de Cobras were discovered by Fontana to be artificial productions, and to consist only of calcined hartshorn.

CO'BRE VERD. See BOJOBI.

COBRE'LLO. See EPILEPSIA.

CO'BUS DE CIPO. See BOITIAPO.

CO'CAO AMERICÆ. See CACAO.

CO'CCA BA'PTICA. See CHERMES.

CO'CCA CNIDIA, or GNI'DIA, (from *κοκκος*, a berry). See CNIDIA GRANA.

COCCA'RUM, (from *κοκκος*, a berry). The name of a very small pill mentioned by Oribasius in his Synop. lib. iii.

COCCEI'RA I'NDICA. See PALMA COCCIFERA.

CO'CCI ORIENTA'LES. See COCCULUS INDICUS.

CO'CCIÆ MINO'RES PIL. *colocynth. pil. cum aloë*. See CATHARTICUM EXTRACTUM.

COCCINI'LLA, (a dim. of *coccus*, a berry,) also called *coccinella*, *ficus Indiæ grana*, *scarabæolus hæmispheericus*, *cochinelifera cochinella*, *coccus Americanus*, *cochinelle*, *coccus Indicus tinctorius*. COCHINEAL. *Coccus cacti* Lin. Syst. Nat. (Gmelin) 2220.

It is an insect, but, as brought to us, appears in little grains, wrinkled, of an irregular figure, convex on one side, and flat or hollow on the other; externally they are of a dark red colour, generally sprinkled with a whitish clammy powder; internally of a deep bright red. It is brought from Mexico and New Spain; but the plant has been lately cultivated in India with some success. The insects are found adhering to the leaves and branches of the opuntia, called *nochetzli*, *nopalli*; or

*nocheznophalli* in New Spain; the AMERICAN PRICKLY PEAR TREE, or INDIAN FIG; *cactus opuntia* Lin. Sp. Pl. 669. The natives carefully collect, preserve, and cure them. The male insects have wings, and are about the size of a flea; the females have no wings, and are larger: when full of young they swell so as to resemble berries, in which state they are swept off from the leaves and branches of the *opuntia* with a pencil; if left until the young ones creep out, the parent dies, and its body becomes an empty husk. From their state when thus hiding their young, they have been styled the gall insect; or, more strictly, the pro (false) gall insect; the true one being the kermes, which belongs to the same genus. It is the female sort that we use for dying scarlet and making carmine. By different management it affords all the shades of red, from the lowest to the highest.

Carmine is a fecula or powder that settles at the bottom of the water in which cochineal hath been mixed: with this the drapers rub scarlet cloth where it has not taken the dye.

Cochineal gives a fine durable red to proof and rectified spirits, and a deep durable crimson to water: both retain their colour when inspissated to an extract.

This insect hath been commended as diuretic, diaphoretic, and corroborant; but they are now employed only for their colour. See Neumann's Chem. Works; Dict. of Chem. Lewis's Mat. Med.

COCCO BALSAMON, (from *κοκκος*, a berry, and *βάλσαμον*, balsam tree). The fruit of the true balsam.

COCCO'NES, (a dim. of *coccus*, a berry). The grains or acini of the pomegranate. See GRANATA MALA.

CO'CCOS, or CO'CCUM. See PALMA COCCIFERA. In Hippocrates, when without any addition, it signifies the cnidia grana: but *coccus* implies any berry or grain.

CO'CCULI INDI AROMA'TICI, (from the same). See PIPER JAMAICENSE.

CO'CCULUS INDI'CUS, called also *cocculæ officinarum*, *cocci orientales*. *Menispermum cocculus* Lin. Sp. Pl. 1468. INDIAN BERRY. It is a brown fruit of the size of a very large pea; rough, brittle, and when perfect hath a white kernel. It is brought from Malabar and the East Indies, where it grows in clusters on a large tree called *natsiatam*. It is poisonous if swallowed, bringing on a nausea, fainting, and convulsion. The noxious quality resides in the kernel, and it operates both as an emetic and purgative. It is only, and rarely, used externally: made into an ointment, or infused in water, it destroys lice more effectually than the stavesacre. Mixed with paste it stupifies fishes so that they will lie on the water, and not attempt to escape from the hand that takes them. Wepfer takes notice of several experiments made with them in his work *De Cicutâ Aquaticâ*. See also Raii Hist. and Neumann's Chem. Works.

CO'CCUM BAPHICUM, *insectorium*, *tinctorium*, *chermesinum* vel *scarlatinum*. See CHERMES.

CO'CCUS DE MALDI'VIA. See PALMA COCCIFERA.

Co'ccus po'lonicus, Co'ccus ra'dicis tinctorius, is found of different sizes, from a poppy seed to a pepper corn, and in greater or less numbers adher-

ing to the roots of the *polygonum cocciferum* of Ray, the *scleranthus perennis* Lin. Sp. Pl. 580. Breynius describes it as being round, smooth, and of a purple violet colour: it has a thin skin, inclosing a blood red juice; one half or more of it is covered with a rough dark brown crust, by which it adheres to the roots. It is gathered in summer and dried in earthen platters. One of these exposed to the sun, by the latter end of July produces a small worm, which, after a few days, lays numerous eggs. The young ones fix to the roots of the plants, or their lowest branches, and suck their juice. These berries are used as a colour in dyeing, for they abound with a purple juice. As a medicine, their virtues are the same with the chermes, and for these they are a good succedaneum. The insect is the *coccus polonicus* Lin. Syst. Nat. (Gmelin) 1218. See Neumann's Chem. Works, and Raii Hist. Plant.

COCCYGÆUS Musc, (so called from *coccyx*, where it is inserted). It arises from the spine of the ischium, and is inserted into the side of the os coccygis; this muscle and its fellow form a sling to bring that bone upwards and inwards. It is only a continuation of the posterior part of the levator ani; *coccygæus posterior* of Winslow.

COCCYGÆUS ANTERIOR, called also *ischio coccygæus*. The muscle is fixed in the anterior portion of the small transverse ligament, at the upper part of the foramen ovale of the os innominatum; from thence it runs between the great transverse ligament of the pelvis and the musculus obturator internus, and is inserted in the lower part of the os coccygis.

COCCYGÆUS POSTERIOR. This muscle is fixed to the inner concave edge of the two first vertebræ of the os sacrum, to the inner and lower edge of the ligamentum sacro-sciaticum, and to the spine of the os ischium, and is inserted in the inside of the os coccygis, above the coccygæus anterior; it is called also *sacro coccygæus*.

CO'CCYGIS OS, (from *κοκκυζ*, a cuckoo, whose bill it is said to represent). Also called *cauda*, *coccyx*, *ossis sacri acumen*. It is situated at the extremity of the os sacrum, and is in some measure an appendix of it; it is bent in a concave form towards the pelvis, to support the rectum and enlarge the cavity of the basin; the fore side is flat, the back part rather convex; it is made up of four or five pieces, like false vertebræ, joined together by cartilages, more or less pliable; sometimes all are cemented together. The first piece is the largest; it consists of two parts, betwixt which and the os sacrum is a notch, through which a pair of nerves pass. The other pieces are irregular squares, diminishing as they descend. In children it is almost wholly cartilaginous.

Daventer and some other writers say, that difficult labours are often caused by these bones being ankylosed: but experience manifests that the difficulty was owing to their impatience; for it is generally found that when the head advances but slowly, or not at all, if we wait, nature generally will perform her office safely and effectually.

CO'CCYS. See PALMA COCCIFERA.

CO'CCYX, *κοκκυζ*. See COCCYGIS OS.

CO'CHIA, (from *κοχῶω*, to make round). A name formerly of some officinal pills. There were two com-

positions bearing this name; the *fil. cochleæ majores* from Rhases, and the *fil. cochleæ minores* from Galen: the first is totally excluded from practice; the second is called *fil. colocynth. cum aloe*, or *extractum colocynthidis compositum*. See COLOCYNTHIS.

COCHLEA, COCHLIAS, (from *κοχλίζω*, to turn round). Called also *antrum buccinosum*. The first mention made of this part of the ear is by Plutarch, who says, that Empedocles, a scholar of Pythagoras, was acquainted with it and its use, for he said that sounds were formed there. It is a winding cavity, which turns round a nucleus in a spiral manner. It is larger where it begins, becoming smaller like a horn; the second turns almost within the first, and the third within the second, making about two turns and a half. It is divided into a superior and an inferior cavity, by a partition in the middle, perpendicular to the axis of the spindle of the cochlea, so that in reality it consists of two semi canals: that part of the partition next to the axis is bony, which terminates in an edge, where it is membranous; it grows narrower towards the apex. The scala, which is next the basis, opens into the tympanum by the fenestra rotunda; that towards the apex into the vestibulum by the fenestra ovalis.

That the cochlea is a part of the organ of hearing may be concluded from its spiral laminæ, which are hard, dry, slender, and easily broken; conditions required in bodies susceptible of tremulous motions. Again, when the large branch of the portio mollis of the seventh pair of nerves arises at the basis of the cochlea, it is divided into a great number of smaller branches, which, passing through all the smaller meatuses with which the spindle is perforated, are distributed to the various windings and meanders of these spiral laminæ, where they are lost. These laminæ are not only calculated for receiving the vibratory motion of the air, but their structure has been looked on as a convincing proof that this part of the organ is qualified and disposed for accommodating itself to the different characters and degrees of sounds; for since it is broader at the beginning of its first circumvolution than at the extremity of its last, and since the breadth of its other parts is in like manner proportionally diminished, its broadest parts are supposed to be fit for the reception of those slow and languid vibrations, which are productive of grave tones, since they may be put into a commotion without the other parts undergoing any change; and, *vice versâ*, that when its narrower parts are struck, their vibrations are brisk and lively, and consequently produce acute tones. Therefore, according to the various commotions of the spiral laminæ, the nerves distributed through its substance may probably receive the various impressions of the air, which exhibit and represent various tones or modulations of sound. See SONUS.

COCHLEA CELA'TA. See ARDROSACE.

COCHLEA FO'SSILIS and LAPIDE'A. See COCHLITA.

COCHLE'E, (from *κοχλῶ*, to wind, or breathe).

#### SNAILS.

The snail is an animal lodged in a short thick turbinated shell, whose aperture is closed in the winter with a kind of cement. The land snails are called *operculares*: that sort which adheres to briars and tendrils of vines are sometimes called *scelton* and *poromaticæ*.

Before the time of Serenus Samonicus, who flourished in the third century after Christ, shell snails were not recommended in phthisical cases. The shell, however, does not alter the nature of the animal.

Snails abound with a viscid slimy juice, which they readily impart, by boiling, to milk or water, so as to render them thick and glutinous. They are a tender substance; easily digestible; very nutritious and demulcent; employed in cases of emaciation and hectic fever: though as animal food they cannot be refrigerant, still perhaps they are only slightly stimulant.

The sea snail, called the *periwinkle*, is often eaten as a common food; in France the land snail, called the *vine shell snail*, is an article of diet; but the small white shell snail is the most valued.

Naturalists describe a great variety; but the large ash coloured snail is said to be that which is intended for medicinal use; though the smaller, dark coloured, spotted, or striped sort, more common in gardens, is taken indiscriminately, and their qualities do not appear to differ.

If salt is put upon the snail it soon dies; but it first contracts itself, so as to force out all its mucus.

COCHLE'A CELA'TA, ANTONOMA'STICA. This is a good shell snail, found in the Mediterranean. Its operculum or cover, is, according to some, the *umbilicus marinus* of the shops.

COCHLE'A MAGARITI'FERA. See CONCHA MAGARITI'FERA.

COCHLE'ARE, (from *cochlea*, a cockle; whose shell its bowl represents). A SPOON. Perhaps so called from resembling a shell. The ancients had two kinds of spoons; the greater, which contained a drachm; and the lesser, which contained a scruple. Various indeed are the accounts of the ancient cochlearia; but in the present London and Edinburgh dispensaries, a large spoonful is, of syrup half an ounce in weight, and of distilled waters three drachms in weight, by measure half an ounce.

COCHLEA'RIA, (from *cochleare*, a spoon; because its leaves are like the bowl of a spoon). SCURVY GRASS, a low plant, with thick juicy leaves, somewhat hollowed, so as to resemble a spoon: those from the root standing on long pedicles; those on the stalk joined close to it without pedicles; producing toward the upper parts of the stalks small white tetrapetalous flowers, followed by roundish seed vessels. It is annual, grows wild in several parts of England, particularly about the sea coasts and salt marshes, and flowers in May, or sooner. In Greenland, and some other northern parts, it is mild and totally destitute of pungency, and yet as effectual as that which grows with us, when eaten for the same purposes: it is the *cochlearia officinalis* Lin. Sp. Pl. 903. The COMMON or GARDEN SCURVY GRASS. A variety of this is the *cochlearia officinalis minor, rotundo folio*. SMALL LEAVED SCURVY GRASS.

COCHLEA'RIA BATA'VIA, called also *cochlearia hortensis*, vel *rotundifolia*; ROUND LEAVED, DUTCH, or GARDEN SCURVY GRASS. The radical leaves are unevenly roundish, those on the stalks oblong. It is cultivated in gardens, and is probably also a variety, though it is said not to change its qualities with the soil.

**COCHLEA'RIA BRITANNICA**, called also *cochlearia marina*, *cochl. folio sinuato*. **ENGLISH OR SEA SCURVY GRASS**. It is the *cochlearia anglica* Lin. Sp. Pl. 903. All its leaves are alike, oblong, pointed, deeply irregularly indented and sinuated.

The fresh leaves of all these plants have a disagreeable smell, and a penetrating acid taste: the first is by much the strongest. The leaves are the strongest part of the plant: they are antiseptic, attenuant, aperient, and diuretic; supposed to open obstructions of the viscera and remoter glands, without heating or irritating. They have long been considered as the most effectual antiscorbutic plants. Sydenham and Lewis recommend the first species highly, combined with arum and wood sorrel, in rheumatic and wandering pains, accompanied with fever. It is said to be of service also in paralytic and cachectic indispositions; but for these purposes its powers are too weak. A small quantity of nutmeg covers their disagreeable flavour.

Their active parts are wholly in the expressed juice. Water or spirit alike extracts their whole virtue. The pungent part exhales in drying, or in evaporating the liquors which contain it.

The method of preserving the herb, with all its virtues, is to beat it up with sugar into a conserve, and keep it in a close vessel. But as an antiscorbutic it is not so beneficial as the fresh plant, or the expressed juice directed in the Pharmacopœias.

The principal virtue has been said to reside in an essential oil, separable in small quantities by distillation in water; this oil sinks in water, yet it is very volatile, subtile, and penetrating, and is carried over in distillation with rectified spirit of wine. A pint of spirit will take with it all the oil from two pounds weight of the leaves. The virtues, however, of all fresh vegetables in scurvy are so nearly the same, that it is not easy to refer them to any one principle; nor, on the whole, is any one preferable. Of equal virtue with the scurvy grass is fresh lemon juice and the tops of turnips. But this is not a place for the discussion. See **SCORBUTUS**. Lewis's Mat. Med.

**SPIRITUS COCHLEA'RIÆ**. Take ten pounds of the leaves of fresh scurvy grass, of rectified spirit of wine five pints: macerate the herb twelve hours, and with a water bath draw off five pints. This is called simple spirit, in contradistinction to what is called golden. The dose is from twenty to a hundred drops. Horse radish may be mixed, or wholly substituted, without any sensible difference in any point of view. In this form, however, the plant is wholly inert, and the preparation is now disused.

**SU'CCUS COCHLEA'RIÆ CO'MPOSITUS**, formerly **SU'CCI SCORBU'TICI**, is prepared by adding two pints of the juice of garden scurvy grass to a pint of the juice of brook lime, as much of the juice of water cresses, and twenty ounces of the juice of Seville oranges; mix them, and after the fæces have subsided, decant off the liquor, and strain. The dose, to be effectual, must be at least a pint in a day. This is antiscorbutic, gently diuretic, and slightly laxative. There is some difficulty in procuring it fine. An apothecary, who had gained the credit of preparing it very neatly, owned that the only secret was, suffering a little fermentation to begin before the juices were strained, which he had been taught by once carelessly neglecting them.

**SU'CCUS COCHLEA'RIÆ AU'REUS**. To a pint of the simple spirit of scurvy grass add an ounce of gamboge. The dose is from twenty to sixty drops, and it operates as an aperient and a stimulating diuretic, added to the virtues of the gamboge, which acts in a mild manner. All the preparations of scurvy grass are now, however, deservedly neglected. See **GAMBOGIA**.

**COCHLEA'RIA ARMORA'CIA**. See **RAPHANUS RUSTICANUS**.

**COCHLEA'TUS**, (from *cochlea*, a snail). In botany it means resembling a snail's shell.

**CO'CHLIAXON**. A name for a part in a machine described by Oribasius.

**COCHLI'TA**, (from *κοχλῆα*, a snail's shell). It is also called *cochlea fossilis* or *lapidea*, and is a stone of the shape and figure of a certain shell snail; said to be lithontriptic.

**COCHO'NE**, (from *κοχῶνα*, to turn round). Galen gives this appellation to the juncture of the ischium, near the seat or breach; whence, says he, all the adjacent parts about the seat are called by the same name. Hippocrates often mentions these parts. Hesychius says, that cochone is the part of the spine adjacent to the os sacrum and breech, and tells us that some call the parts on both sides of the os sacrum by this name; and adds, that the ischia are sometimes thus called.

**COCILIO**. A weight of eleven ounces.

**CO'COS**. See **PALMA COCCIFERA**.

**CO'CTIO**, (from *coquo*, to boil). **BOILING**; and metaphorically **PREPARING**. Also *decoctio* and *apozema*. The effect of boiling differs greatly from that of infusion. In the heat of boiling water the essential oils of vegetables, in which their virtue generally resides, are dissipated; and when the medicine to be obtained is to consist of the more volatile parts of the ingredients, infusion is obviously preferable to decoction. The grosser parts of many substances are only extracted by boiling. The infusions of animal substances are of much lighter digestion than the decoctions; and boiling water extracts, for instance, the rougher and more disagreeable portions of camomile flowers, and the *carduus benedictus*: cold water, the milder and more aromatic.

In decoctions, those ingredients should be boiled first from which their virtues are most difficultly extracted; and those which more readily impart them may be reserved until a later period. Volatile ones may be added when the decoction is removed from the fire; they may stand closely covered until the liquor is cool.

Agglutinants, astringents, and emollients, are the chief subjects of this operation, and such other materials as require some force to separate their parts. See **DECOCTA**.

By decoction the tendency to fermentation in fermentable liquors is lessened. See **Dict. Chem.** 4to.

By the coctions of humours is meant the digestion of the aliment into chyle; the reduction of the chyle into blood; and the separation of the juices from the blood, by means of the glands. These are styled the first, second, and third coction.

**COCU'STA**. See **COURBARIL**.

**CO'CYTA**. See **MALIS**.

**CO'DAGA PA'LA**. See **CONESSI**.

**CODDAM-PU'LLI**. See **CARCAPULI** and **GAMBOGIA**.

**CODESE'LLA**. See **CARBUNCULUS**.

**CO'DIA.** The bulbous head of any plant. In Hippocrates it signifies a poppy head. See **PAPAVER ALBUM**.

**CODIA'MINUM, CODIA'NUM,** (named from its round head). See **NARCISSUS LUTEUS SYLVESTRIS**.

**CODI-AVA'NACU.** An under shrub growing in sandy soils in the East Indies. The juice of the whole plant taken in wine is a good remedy for fluxes. Some other preparations are made from it. We can find no traces of it in later authors: but it is the *tragia chamaelæa* Lin. Sp. Pl. 1391.

**CODOCE'LE,** (from *κωδία*, a bulb, and *κκλη*, a tumour). See **BUBO**.

**CÆCA' LIS VE'NA,** (from *cæcum*, the blind gut through which it runs). A branch from the concave side of the vena meseraica major: it runs to the beginning of the colon; dividing by two arteries, one of which communicates with the gastro-colica; the other, after sending branches to the intestinum cæcum and appendix vermiformis, communicates below with the extremity of the great meseraic vein.

**CÆLA,** (from *κοίλος*, hollow). The hollow of the eyes, or rather above and below the eye lids. They are puffed up in a cachexia. The cæla of the feet are the hollow parts at the bottom of the foot, adjacent to the heels.

**CÆLIA,** (from *κοίλος*, hollow). It signifies a cavity in any part of the body, or in any of the viscera; it is also the same with **ALVUS**: if *ανα* is joined with it, it signifies *stomachus*, and sometimes the *thorax*; with *κατω*, it is the *abdomen*, lower belly, or intestinal tube, from the cardia to the anus.

**CÆLIA'CA ARTE'RIA,** (from *κοιλία*, venter, the belly). The celiac artery arises anteriorly from the aorta descendens, as soon as it has passed through the diaphragm; its trunk is short, but it sends off from the right side two small diaphragmatic arteries, though sometimes there is but one. The left branch, which rises from the intercostales and mammariæ, sends ramifications to the superior orifice of the stomach, and to the glandulæ renales of the same side, as the right furnishes the renal gland on the right side, and the pylorus. After these the celiac artery sends off the arteria ventriculi coronaria, and the gastrica superior; then divides into the arteria hepatica on the right hand, and the arteria splenica on the left. Sometimes this artery is divided into the coronaria, hepatica, and splenica; in the same place, very near its origin, the trunk going out from the aorta in a straight line, and the branches from the trunk almost at right angles, like radii from the axis, whence this trunk has been called *axis arteriæ celiacæ*.

**CÆLIA'CA PASSIO.** The **CÆLIAC PASSION** is a species of diarrhœa, in which the aliment is carried off in a liquid state, but not well digested; the discharges resemble chyle. Aretæus calls those afflicted with this disorder *κοιλιακοί*; Cælius Aurelianus, *ventriculosi*; Hippocrates does not name the disease. Sauvages enumerates four species, the *chylousa*, *purulenta*, *mucosa*, and *lactea*; but the first is generally understood by the *celiac passion*, which is a chronic discharge of liquid indigested aliment: in this disease, on account of the debility of the assimilating power, the aliment is left half digested, and becomes depraved both in colour, smell, and consistence, for the colour is white; there is

a rumbling in the intestines, and flatus is exploded with some violence; the pain of the stomach is severe, resembling pricking; the patient becomes weak and emaciated. The disease continues long, is periodical, and difficult to cure. Dr. Cullen considers it as synonymous with diarrhœa, and mentions it in his third and fourth species, under the terms *mucosa* and *caliaca*, making the purulenta only symptomatic.

It is said to be caused by a disorder in the first passages, which admits of the aliment being dissolved, but not properly digested. Dr. Friend says that it originates from an obstruction of the intestinal glands, on which account a sufficient quantity of lymph cannot, by these, be supplied for diluting the chyle, and rendering it fit to pass into the lacteals; hence it passes off with the excrements. He distinguishes it from the chylous flux, by observing, that in this the cause is an obstruction of the lacteal vessels.

This, though the most simple and obvious view of the subject, admits of many doubts; and its periodical return leads us to consider it in a different view. This explanation will explain the appearances of lientery, but by no means of the celiac passion. As we find a sweet chylous matter occasionally thrown out by the kidneys, sometimes floating in the blood, and in a few instances by the salivary glands, it is more reasonable to suppose that this matter may be again deposited after being received into the circulation. Were it only a discharge from the first passages, opiates and astringents would relieve it, nor should we find its removal rapid, its return irregular, but certain. It is by no means also a symptom of obstructed mesenteric glands; and though the bile is usually wanting, it is more probably concealed by the colour than absent, since we have reason to suppose that chyle is only formed by its means.

It must be distinguished from other intestinal discharges, and from what Celsus calls *caliacus ventriculi morbus*.

The cure is always tedious; often uncertain. The disease sometimes ceases, but, generally, often periodically returns. Astringents are usually prejudicial, and those remedies which gently stimulate the bowels, are manifestly the means of relief. Vomits of ipecacuanha may occasionally be given, and gentle purges frequently repeated in small doses. As the disease seemingly consists in the defective application of the nourishment, exercise, free air, and perhaps sea bathing, would be useful. See **DIARRHŒA** and **DIABETES**.

See Aretæus, lib. ii. cap. 7. Cælius Aurelianus Morb. Chron. lib. iv. cap. 3.

**CÆLIE,** *κοιλίη*. See **VENTER**.

**CÆLI-FLOS, CÆLIFO'LIUM,** (from *cælum*, heavenly, *flos*, or *folium*, a leaf; so called because it was supposed to be a fallen star). In some places it is known by the name of **STAR FALL**. *Purgamentum stellælarum*; commonly *nostoch*. *Tremella nostoch* Lin. Sp. Pl. 1625.

It is a species of jelly, sometimes clear, at others greenish, and agitated with a kind of tremulous motion so long as it is fresh.

It is found after rain in meadows, and in dry parched grounds, generally betwixt the spring and summer seasons. If not gathered before the rising of the sun, it will be shrivelled up to a thin membrane of a brownish colour.

The nostoc is in reality a moss, adhering to the earth by one or more slender roots. The embryo at first appears like a small tubercle; which is fleshy, soft, and diversified with inconsiderable inequalities, like those on strawberries, of a greenish blue colour, but afterwards clear. This membrane is gradually unfolded on the earth, and remains while the weather is moist. It affords a clear insipid liquor, that turns hydrargyrus muriatus white, and syrupus violarum green. It affords a volatile salt well crystallized, ammonia, and a fetid oil. The Germans use it to make the hair grow.

CÆLO'MA, (from *κοιλωμα*, *hollow*). See BOTHERION.

CÆLOSTO'MIA, (from *κοιλω*, *hollow*, and *στομα*, *the mouth*). A defect in speaking, when a person's speech is obscured by sounding, as if his voice proceeded from a cavern.

CÆMENTA'TIO, CÆME'NTUM, (from *cædo*, *to beat together*). CEMENT, also *cæmentum*. It is a tenacious matter, by which two bodies are made to adhere. What is used by the chemists is commonly called *lute*. See LUTUM.

Cements are also those powders and pastes with which any body is surrounded in pots or crucibles, producing, by the help of fire, changes in the substance round which they are spread. The COMMON CEMENT, directed by Schroeder, is the following: take half a pound of finely powdered brick dust, four ounces of common salt, and of nitre and verdigrise, each an ounce.

There are many compositions for cementing, which may be seen in chemical authors; one of the chief is what is called the ROYAL CEMENT, because used in purifying gold and silver. It is made with four parts of fine brick dust, one part of green vitriol, calcined to redness, and one part of common salt: when mixed, they must be worked into a firm paste with water. See Dict. of Chem. 4to. Neumann's Works.

CÆ'NA, (from *κοινος*, *common*; as a meal necessary to all). SUPPER. Suppers that are heavy should be avoided, because digestion produces a slight fever, which increases the natural evening paroxysm; and, though the robust feel no inconvenience from neglecting this rule, the invalid will suffer greatly by the error. Suppers should, therefore, be eaten long before bed time, that they may be nearly digested before the hour of sleep; and then a draught of pure water will usefully dilute what remains in the stomach. Indeed suppers, in many constitutions, are very pernicious; inducing disagreeable dreams, disturbed rest, the incubus or night-mare, particularly in those who have weak digestions.

CÆNO'TES, (from *κοινος*, *common*). The physicians of the Methodic sect asserted, that all diseases arose from relaxation, stricture, or a mixture of both. The last were called *cænoses*, because diseases have these in common.

CÆRU'LEUM MONTA'NUM, (quasi *caeruleus*, from *caelum*, *the sky*, of a sky blue colour.) MOUNTAIN BLUE. It is a blue ore of copper.

CÆRU'LEUM FO'SSILE. See ARMENUS LAPIS.

CÆRU'LEUS LAPIS. See VITRIOLUM CÆRU'LEUM.

CO'FFEA, (from *kofuah*, *mixing together*). Called also *jasminum Arabicum*, *choava*, COFFEE TREE OR BUSH. It is the *coffea Arabica* Lin. Sp. Pl. 245; natural order VOL. I.

*rubiceæ*, called also *bon*. When fit to drink it is then named *caova*.

The tree is of the jessamine kind, with leaves like those of the bay tree: from Arabia Felix it was introduced into the West Indies; but is said to be a native of the higher Æthiopia, from whence it was carried to Persia before it was known in Arabia. The fruit is a juicy berry, including two of the seeds, joined by the flat sides, and covered each with a thin shell. The seeds are of a pale colour and an oval shape, convex on one side, flat on the other, with a remarkable furrow.

Coffee was but little known in Europe before the seventeenth century. The first coffee house in London was erected in the Tilt Yard, in the year 1652. In Paris it was scarcely known until 1669: though at Marseilles it was used in 1644. Rauwolfius, a German, and Prosper Alpinus, an Italian, were the first Europeans who wrote on the use of it.

The Arabian is called the *Levant coffee*, and is the smallest; the Java, the *East Indian coffee*; it is larger and of a whitish livid colour: the American, *English* or *Surinam coffee*; the berries are large, and of a greenish colour; but the best are small, close and somewhat transparent. This last seems to be an indigenous variety of this part of America, and it is doubtful whether the plant is not also a native of Arabia. The Arabic word *cahoua* signifies any kind of liquor, consequently the liquor made with coffee. Hence the Turks derive their *cahveh*; whence again the European word *café*. In Arabia, persons of rank only use the seminal capsules, and the pellicles immediately covering the berries; these produce a grateful liquor, but for this purpose the capsules must be fresh. The French call this *café à la sultane*.

The coffee berries have a farinaceous, somewhat unctuous, bitterish taste, and little or no smell. They are roasted to destroy the watery part of the mucilage, and, of course, that flatulence that they have in common with all farinaceous substances. Many seeds by roasting acquire the flavour for which coffee is admired. Dillenius hath enumerated in the Ephemerides Naturæ Curiosorum the substances which in smell and taste resemble coffee; and finds that roasted rye, with a few roasted almonds to furnish the necessary proportion of oil, comes the nearest to it.

Coffee contains a large portion of acid, a gummy, resinous, and astringent extract, a large proportion of oil, and some salts. The oil in roasting becomes empyreumatic, and gives the desired flavour.

From sixteen ounces of roasted coffee, Neumann obtained seven ounces, two drachms, and two scruples of watery extract; and afterwards five drachms and one scruple of spirituous extract. On reversing the operation, he obtained four ounces and four scruples of spirituous extract, and four ounces of watery: the residuum, in both cases, was nearly the same; viz. about one half of the whole.

The roasted seeds ground into powder soon lose their flavour in the air, impart it to water and to spirit by light coction or digestion, and give over a great part of it with water in distillation. The roasted berries keep very well; and, to recover their brisk flavour, lay them before the fire a few minutes, and, when warm, they may be ground for use; they are then as agreeable as when first roasted.

Coffee should be boiled eight or twelve hours before it is drunk; and if the liquor is mixed with an equal quantity of milk it is excellent.

It is the most approved method to prepare the coffee by infusion only. An ounce and quarter of coffee is allowed to a pint of water, which must be added in a boiling state, and continue simmering, closely covered, for two hours. In this time it must be frequently shaken, or agitated with a chocolate mill: in the common vessel, styled the coffee biggin, it is prepared very completely. The inferiority of the West Indian to the Levant coffee, is said to arise from plucking the berries too soon. They are then larger, but have not attained their true flavour.

If coffee is drunk warm within an hour after dinner, it is of singular use to those who have head aches from a weakness in the stomach, contracted by too great attention, or from irregularity. The phlegmatic and corpulent are much benefited by its use. In some delicate habits it produces nervous symptoms; but, in general, gives cheerfulness and serenity of mind. It soon carries off the disagreeable effects of opium; and has been said, by sir John Pringle, to relieve obstinate spasmodic asthma. It certainly prevents sleep in many constitutions; and we have known it prove a quick, easy, laxative. Prosper Alpinus is immoderate in his praises of coffee; and the Persians say it was revealed by the angel Gabriel, to relieve Mahomet after his fatigues. It is slightly astringent and antiseptic, moderates alimentary fermentation, and is powerfully sedative. Drunk too soon after port wine, it often produces a disagreeable acidity in the stomach; and indeed an acidity is obvious, at once, to the taste, on mixing coffee and port wine. See Lewis's Mat. Med.; Neumann's Chem. Works; Percival's Ess. Med. and Exp. vol. ii.; Lettsom's edit. of Fothergill's Works, vol. ii.

COHOBA'TIO, COHO'BIUM, COHOPH. COHOBATION. It is the returning a liquor, distilled from any substance, back again upon the same substance, and redistilling it with or without an addition of fresh ingredients. The alenbic, called a pelican, was invented for the more easily effecting this operation; modern chemists neglect it. Paracelsus uses the word *cohob* when a disease does not easily yield to the remedies applied. Medicines, therefore, are to be given secundum cohob; that is, repeated at intervals.

CO'HOL, (from *cohol*, *antimony*). See ALCOHOL. Castellus says, that it is used in Avicenna to express collyria for the eyes, in fine powder.

CO'LIMA, (from *κοιλια*, *the bowels*). A sudden swelling of the belly from wind.

CO'IRA. See TERRA JAPONICA.

COI'TIO, (from *coëo*, *to cohabit*). The act of venery. See VENUS.

COLATO'RIA LACTE'A. See FLUOR ALBUS.

COLATO'RIMUM, (from *colo*, *to strain*). A STRAINER of any kind.

COLATU'RA, (from the same). Any strained or filtered liquor. See DEPURATIO.

COLCAQUAHUI'TL. An American plant, commended in palsies and uterine disorders. Raii Hist.

COLCESTRE'NSIS A'QUA. COLCHESTER WATER. This mineral water is of the bitter purging kind, similar to that at Epsom, but not so strong. See AQUÆ MINERALES.

CO'LCHICUM, (from *Colchis*, a city in Asia, where this plant abounds). Called also *coum*, *colchicum commune*; *Anglicum*, *purpureum*, *et album*. *Colchicum autumnale* Lin. Sp. Pl. 485. Nat. Ord. *liliaceæ* of Murray. MEADOW SAFFRON.

It grows in meadows that are moist and rich, and sometimes in marshy grounds. It hath two fleshy bulbous roots; the one producing, from its lower part, a smaller bulb. From the last arises, in autumn, along a furrow, in the side of the old root, a slender, hollow, transparent pedicle; widening at the top into a flower, like that of a crocus; divided into six segments, of a purplish or whitish colour; withering in two or three days. From the same root spring, early in the following season, three or four upright leaves, like those of the lily; in the middle of which appear, on short pedicles, commonly three triangular pods, about the size of small walnuts, divided into three cells, full of roundish dark coloured seeds. The outer root is barren and shrivelled, the inner one produces the plant.

When the root is young and fresh, its taste is very acrid; but, when old, it is mealy and faint. For medicinal purposes it is best when full of sap. Two drachms of this root killed a large dog; after occasioning violent pain for about thirteen hours, it operated by vomit, stool, and urine. One grain of it swallowed by a healthy man produced heat in the stomach, and, soon after, flushing heats in different parts of the body, with frequent shiverings, followed by colic pains: itching in the loins and urinary passages was soon afterwards perceived, and then came on a continual inclination to make water, a tenesmus, pain in the head, a rapid pulse, thirst, and other disagreeable symptoms.

Notwithstanding these effects, when dissolved in vinegar, or made into an oxymel, it becomes a safe, but powerful medicine. The roots should be fresh and full of sap when they are used. In slicing them, they emit acrid particles, which affect the head, irritate the nostrils, throat, and breast; the fingers which hold them, when cutting, are benumbed for a time. Their acrimony is wholly taken up by vinegar.

When this root is imprudently swallowed, a pint of water, with an ounce of vinegar, or lemon juice, and half an ounce of the syrup of poppy heads, form a salutary mixture, which should be drunk frequently.

ACE'TUM CO'LCHICI. Take of the fresh roots of meadow saffron, sliced, an ounce; white wine vinegar, a pint. Mix and digest in a glass vessel, over a gentle fire, during forty-eight hours; then strain the liquor.

This vinegar is made into an oxymel, by adding to each pint two pounds of clarified honey, mixing them by boiling. This is the *oxymel colchici* of the London Dispensatory.

As it is of consequence that the bulbs be in perfection, they should be taken up in autumn.

This oxymel is agreeably acid, gently pungent, and moderately astringent, clearing the tongue effectually from mucus. In an increased dose it is an emetic, and sometimes purgative; but its most general effect is diuretic, and as such it is very constant, and remarkably powerful.

The dose should be small at the first; half a teaspoonful may be given two or three times a day, increasing the dose as the stomach will admit. In dropsies and tertian agues its success has been great; as an

expectorant, it succeeds when squills fail; and when opiates are joined with expectorants, this oxymel should be preferred, for no medicines in conjunction interfere with its operation. See Dr. Storck's Essay on the Use and Effects of the Root of the *Colchicum Autumnale*. For its use in dropsies, see *London Med. Journal*, vol. i. p. 395. In Germany and France, it continues still to be a favourite medicine. In England, it is generally thought a less efficacious diuretic than the squill, which yet excels it as an expectorant. We have, however, often found it a more effectual diuretic.

CO'LCHICUM ILLYRICUM. See HERMODACTYLUS.

CO'LCHICUM ZEYLA'NICUM. See ZEDOARIA.

CO'LCOTAR. See VITRIOLUM.

CO'LCOTHAR, SAL, is the salt obtained when the colcothar of vitriol is washed in water; it is also named fixed salt of vitriol. If borax is added to this salt, and the mixture exposed to the fire, it easily sublimes in the form of silver-coloured saline flowers, thus forming the *sal sedativus Hombergii*; already mentioned as the acid of borax (see CHEMISTRY). Two ounces of this salt of vitriol, well calcined, must be dissolved in a quart of warm water; the same quantity of borax must be dissolved also in a quart of warm water: these solutions being mixed and filtered, the clear liquor must be evaporated in a glass alembic to dryness, then the dry mass must be sublimed. By mixing oil of vitriol with twice its weight of borax, the same sedative salt may be more easily obtained.

COLD. Cold is an agent peculiarly powerful in producing diseases, and removing them; indeed almost the fabled spear, which heals the wounds that it has inflicted. Though we have styled cold an agent, it is seemingly a privation of heat; and the application of cold to the human body, is only the application of such bodies which powerfully attract heat in consequence of their lower temperature: apparently, in some cases, from their possessing a greater affinity for caloric, or from carrying off heat in consequence of their evaporation.

In the human body, cold is a relative term. We style it cold when the thermometer is at 70°, if it has suddenly sunk from 84° to that point; but it is cold only at 32°, if the air has been long at 40°, with little wind. Temperate heat is generally placed at 62°; but the uniform heat of the earth in England is about 51°. From about these two last points—for, from many circumstances, there must be a considerable variety—cold diminishes the irritability of moving fibres: they contract more slowly; but, as cold condenses the skin, it presses more firmly on the subjacent vessels, and gives additional tone to the whole system. This effect of general pressure is evinced by the hilarity which we feel in a dense elastic atmosphere; and the same effect sometimes arises even from the support of clothes: an advantage felt by the weak and irritable of the softer sex. In this state of the atmosphere, the perspiration is diminished; but the discharge of that gaseous, insensible halitus, which contributes so powerfully to our feelings of health, seems to be continued with unabated vigour, and to be occasionally increased. The discharges from the bronchial glands, from the lacrymal, and from those of the whole Schneiderian membrane, are augmented; and these, with the increased discharge of urine, seem chiefly to supply the deficiency of the perspiration: for

in steady continued cold, the bowels are by no means relaxed, often in a contrary state.

The nervous system seems to suffer in nearly the same manner with the moving fibres. Its sensibility is diminished; but the mental powers, we mean the intellectual, do not suffer. They seem to acquire vigour with the tone of the body; while tenderness, sensibility, and those feelings connected with an irritable system, are, in proportion, less acute. The stomach, which partakes of the state of the nerves and moving fibres, experiences an increased tone. Its functions are less rapid, but performed more perfectly; and, for similar reasons, the bowels are frequently less active, and the nutritious particles, by delay, more completely separated. In short, if we were to fix the limits where the animal system was in its most perfect vigour, we should say it was in those regions where the heat seldom rises above 70°, or falls below 32°.

When, during a great part of the year, the heat is below the latter point, we find all the effects mentioned more striking, except the vigour of the intellectual faculties. When the irritability is further lessened, strength of mind becomes torpor; energy and vigour are sunk in sensibility, and roused only by violent causes to temporary exertions. When still further lessened, the distinguishing features of humanity are almost wholly lost. Even parental affection has little influence; and the great duties of religion are heard with indifference. The exertions necessary for the support of life, few as they are, occupy the mind and body. Love, which in warmer and more genial climates refines the heart, and awakens every finer feeling, here sinks into an animal passion, neither importunate nor refined; and the same want of irritability protracts the period of puberty, and lessens the proportional number of the offspring. A truly wise provision, where the means of support are so scanty.

The temporary effects of cold we have, in part, anticipated, under the article of BATHING, q. v. All the changes just noticed come on rapidly; but the accumulated irritability, when no longer repressed, restores the glow. If, however, the cause continues, the debility is increased; the pulse flutters with an irregular, interrupted action; the senses become gradually weaker; a propensity to sleep so irresistible, that the victim is content to purchase it with his life, supervenes, and death creeps imperceptibly on this lethargy. The torpid animal, who passes his winter in this state of apparent death, recovers on the approach of spring. His irritability, suspended for a time, is accumulated; and he wakes from his death-like sleep with new vigour. When examined with a microscope, the vessels appear like dark lines; for the fluids are apparently coagulated. The action is first perceived in the vessels: this breaks the line into minute portions before these become undistinguishable in a circulating fluid.

The partial action of cold has similar effects; but they are confined to the part only. The bulk of the organ is diminished; the vessels are less distinguishable; the skin becomes pale; and, if the cold is too long continued, its life is destroyed. Before, however, this last effect takes place, we avail ourselves of the change: the hernia is reduced; the puerperal discharge checked; inflammation diminished.

The diseases which cold produces are not numerous, if we speak only of continued cold. It checks, as we have said, the growth; it protracts the period of puberty; and renders the female less prolific. All these, however, are within the limits of health: and we may as well say, that the Italian female, full of fire and passion, is diseased from excess of fulness and irritability, as the Laplander from the defect of both. But, when the paucity of the menstrual discharge becomes a suppression; when the circulation can be no longer carried to the extremities, but chilblains and sphacelus affect the fingers and toes; when the whole system languishes; disease must be present. Yet, if we consider the variety of climates; the rigour of the arctic winters; the hardships of the Esquimaux, or of the sailor, in pursuit of the whale and seal; when we see, at the same time, the few diseases to which they are subject; we are almost tempted to assert, that continued cold is very rarely the cause of disease.

The principal disorders attributed to cold are owing to its irregular application to the body overheated, or to a partial stream of cold air on one particular organ. From hence arise catarrhs, with all their attendant symptoms, and their accustomed danger; from hence fevers, rheumatisms, diarrhoea, and all the variety of epidemics, with their attendant evils, date their origin. Even the most destructive miasmata often rest innocuous in the body, unless excited to action by cold; and when we hinted that all catarrhs may originate from miasmata, we admitted that cold was an exciting cause.

In this enumeration we have omitted two diseases attributed to cold: the chaps on the lips and skin, from the contraction of cold air; and the fragility of the bones, the *fragile vitreum* of Gaubius, supposed to be equally the effect of condensation. The former are scarcely diseases; and there is much reason to conclude, that the deep seated bones are little affected by the inclemency of the air. The internal parts preserve their usual heat in air of every temperature, without increase or diminution, as we have already shown; and if fractures are more common in cold weather, it must be recollected that our steps are then more unsteady, the ground harder, and irregularly uneven.

It has been contended, that cold is, in its primary action, a stimulant; but the idea arises from the refinements of system, rather than observation. From the first effects of cold, what has been styled reaction so suddenly follows, as to mislead the incurious or the prejudiced attendant. The dispute will, however, at last, become verbal: for it is in no case contended that its stimulus will be injurious; and generally admitted, that with little, often imperceptible stimulus, it may be quickly rendered a powerful sedative.

If we look to cold as a remedy, we shall find a more cheering prospect. In our observations on cold bathing, we have distinguished it in its immediate, its continued, and repeated action. When we speak of cold in this place, we treat chiefly of its immediate and its continued action; for cold applications are principally useful in these ways. We were almost led to confine our remarks to the latter; but there are some facts which will not admit wholly of this explanation.

Cold is highly useful in *FEVERS* of almost every kind, though it will often admit only of the slight application

of cold air; and rheumatic fevers seem to be the only exception. The heat forms the true indication for its use; since, in the early stage of intermittents, or in the exhausted state of protracted typhi, it is less admissible. When there is considerable heat, and no fixed organic affection of the internal parts, cold is often a very salutary remedy. We have, indeed, some instances, where, in a protracted cold fit, the application of cold has hastened the reaction; but the practice will be dangerous, unless the patient is strong and active. The effect of cold in the hot fit of fevers is to lessen the heat, and hasten the perspiration. This discharge is checked when the heat is considerable, and seldom takes place when it is much above 100°. Dr. Alexander places the perspirable heat too high, viz. at 108°.

*Synocha* is well adapted to this remedy; but it seldom occurs without the combination of internal inflammation, except when owing to worms, or sordes in the abdomen. In each case, cold must be employed with some caution and discrimination. Yet cool air and cool drinks may be allowed. Let us take this opportunity of making the distinction. By *cold*, when we speak of drinks, we mean, in general, from 51° to 40°; by *cool*, from 48° to 60°. The coolness of air is more relative; and, in general, means from 10° to 15° below the mean heat of the chamber, which should never exceed, if possible, 62°. It will be obvious, that these numbers are not to be taken with minute precision, but only as a general standard.

In *typhus*, the use of cold is a subject of greater nicety. Cool air and cool drinks are always proper, except when the patient sinks from faintness. Yet De Haen, as we have already observed, used it in a low epidemic fever, at Breslaw, with some appearance of success; Dr. Gregory has sponged the body with cold water or vinegar; and the practitioners of America have employed it even more boldly in this, and its kindred disease, the yellow fever. The exhibition of calomel, at the same time, does not seem to deter them; and, indeed, till some effect on the gums appears, no benefit is derived from the medicine. Should it produce this peculiar symptom, its worst consequence, little disadvantage would probably arise. In some instances, very cold water has been employed as a clyster; and ice, in a bladder, applied to the stomach, or other parts, suffering under acute pain. From ourselves we can say little; we have, in a few instances, employed it certainly without injury; we can scarcely say with any striking advantage. Where the heat is great, it may be most freely used: when inconsiderable, sponging is the most advisable application of cold, and vinegar mixed with water may have its advantages. The different parts of the body should be sponged also in succession.

*PHLEGMASIE.* *Ophthalmia* has been constantly benefited by cold applications; and the fact is so generally understood, that we need not enlarge on it. Even ether, which produces a considerable degree of cold by evaporation, has been employed. *Cynanche*, we are told by Dr. Rogers, is relieved in the northern climates by rubbing ice externally on the throat. A practice not very dissimilar is recommended in some parts of England, holding a piece of nitre or sal prunella in the mouth. Some caution is necessary, that this remedy be not employed in the malignant angina. In *phrenitis*, the

utility of cold applications is sufficiently known and well established: but in the other internal inflammation it is a suspicious remedy. From its utility in *hernia* we may be led to employ it in *enteritis*. In this disease, cold water has been dashed against the legs and thighs with advantage; but it will be recollected, that, in *hernia*, *enteritis*, and *cynanche*, we approach so near the part affected, that the cold is almost an external application; and, though we have mentioned among the effects of cold a costive state, we then spoke of its continued application in a cold climate. In *nephritis* we are told, by Mercurialis, that cold is useful; and, as we can so nearly reach the bladder, either by the perinæum or above the pubes, we suspect it may be useful also in *cystitis*.

In external *phlegmone*, and all inflammations of the joints, cold is a more doubtful remedy. It has never, we believe, been employed in rheumatism; and in gout we still think it must be injurious. In strains, in the white swellings of the knee, and in the morbus coxarius, cold, in the early stages, is advantageous; and it is rendered more effectual, by increasing the momentum of the water, the form in which it is usually employed, by pumping, which also regularly renews the cold application to the part.

In the *HÆMORRHAGIÆ*, with scarcely, if any, exception, cold is useful; and cold drinks, cold air, cold applications, are of the greatest importance. Even in hæmorrhages from the lungs it may be employed with little apprehension; and nitre, a remedy so powerful in every case of hæmorrhages, acts only by the cold which it produces. *Hæmorrhages from the uterus* are restrained by cold, though they often require it in the most active degree; and, perhaps, iced injections into the rectum would be serviceable. Cold injections in the *hæmorrhoides* are powerful and efficacious remedies. Cold is, perhaps, best adapted to the active hæmorrhages; but even those from debility and tenuity of the blood reap little less advantage from its use.

In the *EXANTHEMATA*, cold is also a very useful remedy. In the *small pox*, we know it is freely and advantageously employed in the form of cold air and cold drinks. Accident has even shown, that cold bathing, in the worst kinds of the complaint, has preserved the patient from the most imminent danger. If, however, cold is used in these eruptive diseases, it must be employed with steadiness and perseverance. Slight cold, soon discontinued, will be rather injurious than beneficial. The effect of cold in these cases is to moderate the too active determination to the skin; which, pouring the fluids under the cuticle faster than they can be transmitted, are detained, and by their irritation produce the peculiar pustules. When this determination is restrained, moderate perspiration, or the insensible halitus, which we have before called, with Chenot, the *diaphnœ*, succeeds. The eruption of the small pox may be thus in a great degree, or even entirely, suspended with safety: we scarcely dare to say the same of the other exanthemata.

In *measles*, the poison is directed to the eyes, the bronchial glands, and often to the breast. These affections have prevented the free use of cold. In *peripneumony*, the advocates for its use can only allege, that when cold has been employed in other diseases with which the *peripneumony* was complicated, it has done

no injury. In *catarrh* we find a few instances, but from a suspicious source, in which it is said to have been useful; but, on the whole, we find little foundation for pronouncing cold *even generally* safe in affections of the breast. We must, therefore, dissuade the practitioner from employing it in *measles*; nor is it necessary, when we find that we can easily diminish all the dangerous symptoms by cathartics. In *scarlatina*, the experience of Dr. Currie, and the decisive conduct of Dr. Gregory, have established the utility of cold affusions. They are employed to counteract the heat, and must be continued while any considerable heat remains.

In the *miliaria*, the use of cold drinks and cool air has been long established; and such is their success, either in preventing or removing the disease, that we seldom want actual cold: at least such has been the fortune of the author. In violent cases, there is certainly no objection to actual cold.

In *erysipelas*, some apprehensions have been entertained of the effects of cold as a repellent; we believe without foundation. When, in this disease, the brain is affected, subsequent to the tumour and inflammation of the face and head, the latter does not subside: it is a continuance of the same affection, or rather a greater extent of disease; and authors of credit have employed it with success.

In the *plague*, if it be really a genus of this order, our late experience in Egypt has fully established the advantages of cold applications, cold air, and cold affusions. These are particularly said to prevent bubos; and it is highly probable that considerable and continued cold would be useful to anthrax and other situations. The practitioner should, however, recollect, that anthrax is sometimes *apparently* critical.

*Profluvia*, the next order, contains but two genera; and in one of these, *catarrh*, we have said that cold is inadmissible: yet in the epidemic *catarrh*, cool air and cool drinks have been generally useful. We know not that the application of cold has been carried further.

In *dysentery*, cold affusions are recommended by Dr. Lind. An Italian physician, Signor Rosa, recommends clysters of the coldest water.

In the *sanguineous apoplexy* (of the order *COMATA*), cold applications will undoubtedly be useful; but we find little authority for their use. In the *hydrocephalus*, which has been lately classed under this genus, the coldest water applied to the head is said, by Dr. Rush, to be serviceable; but it is not easy to say in so early a stage what the disease really is. Little danger will, however, probably ensue from cold applications in any kind of headach. The apoplexy from narcotic poisons is always greatly relieved by cold applications. (See *BATHING*). Tissot mentions the good effects of cold affusions in the *coup de soleil*. In partial palsies, pumping on the affected limb, and then covering it with warm flannel, is often serviceable; and in weak joints, a similar remedy is equally beneficial.

In the *SPASMI*, cold is chiefly useful in the form of cold bathing, which we have already noticed. In *colic* and *cholera*, cold drinks will be useful; but they should be administered with caution in small quantities, frequently repeated.

The success of cold, in every form, in *maniacal cases*, is well established by a great variety of the most respectable evidence; particularly of cold applications to the head. In *tympanites* it is recommended by Dr.

Cullen; and in *ischuria*, placing the patient on a wet stone floor, on his naked feet, has often removed the obstruction. It has been common to recommend bathing *scrofulous tumours* with sea water: but the effect is apparently from the cold; and we have often employed common water with similar success. In *burns* we have already mentioned the utility of cold water. See *COMBUSTIO*.

It may not be amiss to add an account of some easy methods of producing a considerable degree of cold. When ice or snow are to be procured, we want no further assistance, for we can cool water only to the freezing point. When these are not at hand, water from a deep well will be found to be at the heat of about 50°. By adding gradually a mixture of nitre and crude sal ammoniac (muriated ammonia), in the proportion of 8 to 5, this water may be gradually cooled down to about 38°. When we reflect that the heat of the body is 98°, and that of the diseased part at least 104°, even the first degree will be considerable; and by repeating the application we shall often obtain the expected relief. From the water artificially cooled, the benefit may be increased. But if this water be put into a bladder, and moistened with ether, spirit of wine, or indeed with common water, in a free current of air, the temperature will be nearly that of ice, and fully equal to any of the indications before laid down. The greatest extremity of cold required, is in some cases of puerperal uterine hæmorrhage. In this we have known the patient exposed to the severest winter cold, covered only with a sheet, which has been kept constantly wetted; and life has been only preserved by such severe treatment. But we must repeat that in every case, where cold is indicated, its use must be steady and constant.

CO'LES, or CO'LIS, (from *καυλος*, a stalk). See *PENIS*.

CO'LI DE'XTRUM, LIGAME'NTUM. Where the mesentery changes its name for that of mesocolon (near the extremity of the ileum) the particular lamina, which is turned to the right side, forms a small transverse fold, which is thus named.

CO'LI SINI'STRUM, LIGAME'NTUM. It is a contraction of the mesocolon, a little below the left kidney.

CO'LICA, (from *κωλον*, colon, the name of one of the intestines). The colic; sometimes called *rachialgia*; but this term is more particularly confined to the *colica pictonum*, the second species.

The appellation of colic is commonly given to all pains of the abdomen, almost indiscriminately; but from the different causes and circumstances of this disorder, it is differently denominated, and some difference in the mode of cure is also to be observed in different cases.

When the pain is accompanied with a vomiting of bile, or with obstinate costiveness, it is called a *bilious colic*; if flatus causes the pain, that is, if attended with temporary distention, relieved by the discharge of wind, it takes the name of *flatulent* or *windy colic*; when accompanied with symptoms of heat and inflammation, it takes the name of *inflammatory colic*, or *enteritis*. The different kinds seem to be properly included, under the distinctions of inflammatory, spasmodic, and flatulent colic.

The inflammatory is when actual inflammation seizes

some part of the intestinal canal; the disorder will then be considered and treated as an inflammation of the respective part. See *INFLAMMATIO VENTRICULI* and *INTESTINORUM*.

The *spasmodic* is when pain affects the belly principally about the navel, attended with an obstinate costiveness, and either a nausea, or actual vomiting. In the beginning it is without inflammation, though inflammation is often a consequence.

Dr. Cullen places this genus of disease in the class *neuroses*, and order *spasmi*; and defines it, pain of the abdomen, particularly round the umbilicus, attended with vomiting and costiveness. He enumerates seven species.

1. CO'LICA SPASMODICA, with retraction of the navel; and spasm of the muscles of the belly.

2. CO'LICA PICTONUM, called also *rachialgia pictonum*; *metallica*; *traumatica*. It is also called *bellon*, when produced by lead. Beasts and poultry, as well as men, are subject to it, if in the vicinity of smelting houses. The symptoms of this species in men are a sense of weight or uneasiness, first affecting the abdomen, particularly round the navel; succeeded by pain, in the beginning slight, not continued, and increased especially after eating: at length the pain is more violent, and remains almost constant, terminating in paralysis.

3. CO'LICA STERCORARIA, which happens from obstinate and long continued costiveness.

4. CO'LICA ACCIDENTALIS, called also *cholera sicca*, from acrid undigested matters.

5. CO'LICA MECONIALIS, in infants, from a retention of meconium.

6. CO'LICA CALLOSA, from a sensation of a stricture in some part of the colon, and frequently of previous flatulence gradually passing off; the habit costive, or fæces liquid, and in small quantity.

7. CO'LICA CALCULOSA, from calculi formed in the intestines, attended with a fixed hardness in some part of the abdomen. It is distinguished by the previous discharge of calculi.

8. CO'LICA FLATULENTA may be added to these species. It is distinguished by a sudden fulness, with pain and constipation, relieved by a discharge of wind from the mouth or anus.

The early symptoms of the two first species do not greatly differ. A pain, chiefly confined to the umbilicus, with a costiveness, attends both. The difference arises from a more peculiar obstinacy of the bowels in *colica pictonum*, from its attacking in paroxysms, and from a weakness of the hands soon coming on. It is styled from the place where it is endemial, the Poitou, the Surinam, the Devonshire colic; from its victims, the plumbers and the painters colic; from its symptoms, the dry belly ach, the nervous and spasmodic colic. It has been attributed to the poison of lead; and this is undoubtedly the cause, when it occurs to glaziers, painters, and those employed in lead works; but though this is one, it is by no means the only, cause. In Devonshire it certainly more often arises from the early cyder, made of harsh, unripe fruit, and in the West Indies from new rum. The whole region of the intestines is the subject of this disorder: in any part of them it may manifest its presence; but in whatever part the true colic occurs, the pain is usually felt round the navel. The real spasm is often very distant. If the lower part of the

colon, or the intestinum rectum, is affected, the colon in the left hypochondrium, towards the spleen, together with that part of it which is seated beneath the stomach, and near the liver, become greatly inflated. When, as it often happens in hypochondriac and hysteric disorders, the beginning of the jejunum, or the end of the duodenum, is spasmodically affected, a severe pain in the loins, on account of the superior mesenteric and intercostal branch of the nerves, which spread themselves on the jejunum, comes on; but more probably from the attachment of the mesentery. In this case the duodenum and stomach are inflated, the breathing is considerably affected, and great anxiety follows.

Spasms may be excited by extraordinary agitations or uneasiness of mind; or by acrid and stimulating matter thrown upon the bowels. Bile, and other excrementitious sordes, may be too long retained, or change their milder qualities; acrid substances may be swallowed, or conveyed to the intestines by other means; particularly lead from vapours, as well as its solutions in different ways. This cause is, however, comparatively very uncommon. Gouty matter diverted from its original seat to the intestines, worms, obstructed periodical evacuations, may have a similar effect.

Whatever be the cause, the approach and progress of this disorder are nearly the same. It begins with a sense of weight, or pain, at the pit of the stomach, attended with loss of appetite, yellowness in the countenance, a slight sickness, and costiveness; the pain gradually increases, no longer wanders, but becomes fixed about the navel, from whence painful dartings proceed in various directions; wherever pain is felt, a soreness and tenderness remain some time afterwards. The sickness increases with the pain, and, at length, a vomiting of bilious matter comes on; the urine is diminished in its usual quantity, and a tenesmus sometimes adds to the distress. While the pain is spasmodic, the pulse remains unaffected, except concurring circumstances produce a change in it; the urine is various; if the smaller intestines are the seat of the pain, it is felt more acutely; if the larger intestines are the parts aggrieved, the sense of pain is more dull and heavy; sometimes there is a bitter taste in the mouth, and a yellowness in the countenance: if the symptoms are not relieved, an inflammation or a gangrene may ensue; or the excrements returning, are ejected by vomit, and death soon follows.

The colic should be distinguished from a fit of the gravel; stones passing through the ureters; rheumatic pains in the muscles of the belly; a beginning dysentery; the blind piles; from a stone passing through the gall-duct; and from the more transitory flatulent pains, styled flatulent colic. Gravel in the kidney produces often colic pains, not easily distinguishable; but, when stones pass through the ureters, the testicle on that side is often retracted, the leg is benumbed, a pain shoots down the inside of the thigh; symptoms occasioned by the stone passing through the ureter over the spermatic chord, or the sacro sciatic nerve. Rheumatic pains in the muscles of the belly rarely affect so accurately the umbilical region, but dart, in various directions, to the chest or to the pelvis, and are attended with soreness, not confined to the abdomen. A beginning dysentery differs little from colic, and the remedies are the same. The pain from the blind piles is confined to the rectum; and that

from a stone in the gall duct is felt in the pit of the stomach, occasionally shooting through the body to the back.

Of the remarkable symptoms that sometimes come on in consequence of this disorder, a palsy is the chief. Dr. Thierry says, that it is the natural crisis of a colic; but, in general, it accompanies the colic from lead, though it sometimes follows colic where this cause is not suspected. It sometimes comes on during the fit, but more generally follows.

When the colic attacks with a shivering, and the pain is very violent, great danger attends it, for an inflammation usually follows. A sweat, a salivation, an hæmorrhage at the nose, or from the hæmorrhoidal veins, spontaneously occurring, is said sometimes to terminate the colic: though, if after the strength is exhausted a colliquative sweat come on, the danger is considerable. If the violence of the pain continues to increase, and the pains suddenly cease, fatal consequences are to be expected.

As preventatives of this complaint, those who are at times afflicted with pains in the belly, should be careful to keep from all violent agitations of the mind; shun exposures to the northern winds; keep the feet dry and warm; abstain from flatulent food and spirituous liquors; and attend carefully to the bowels, to prevent constipation. Those whose occupation subjects them to the fumes of lead, or to the influence of any of its preparations, should breakfast on fat hroth, or eat bread that is spread with sweet lard, before they begin their work; and frequently interpose oily purgatives.

As a spasm is the immediate cause, its resolution is the chief indication of cure; for this purpose, relaxing and antispasmodic medicines, with purges, which, while they solicit the internal discharge, will not greatly increase the morbid irritation, are the more proper means.

If the pains are violent, and the pulse full, some blood may be taken, in proportion to the strength: vomits must be carefully avoided; for, if any irritability of the stomach, afterwards so troublesome, be induced, it will not be easily quieted.

Opium should be next given; and the dose, which may be more or less, according to the violence of the pain, must be repeated every two or three hours, until ease is obtained.

As soon as, by a due use of opium, the sickness and pain abate,  $\mathfrak{z}$  ii. of the sal catharticum amarum may be taken in warm water: if repeated every two hours, it will operate sometimes with sufficient efficacy; though the ol. ricini should be preferred, if the stomach will bear it, because its repetition need not be so frequent. The ol. ricini may be given to  $\mathfrak{z}$  ss. with any warm agreeable mixture. If the ol. ricini is not to be procured, any other purgative, not painful in its operation, may be used. When a free passage is obtained downwards, laxatives must still be continued, until all danger of a relapse is removed.

It often happens, however, that these and every purgative are rejected; and, in the continuance of the disorder, the obstruction is too firmly fixed to be removed by such gentle medicines. We must then apply to more active ones; and the infusion of sena  $\mathfrak{z}$  iv. with manna, sal rupellens, tinct. senæ and jalap. aa.  $\mathfrak{z}$  ss. will form a mixture, of which two or three spoonfuls may be given every two hours. Should this fail, two scruples of

the colocynth pill, with 15 grains of calomel, may be formed into ten pills, two of which may be given every two hours till stools are procured. At the same time, the bowels must be solicited downwards by clysters. A convenient one is half an ounce of common soap, or as much black soft soap, dissolved in three quarters of a pint of water, to which an equal quantity of milk should be added. If this fails, three drachms of colocynth, boiled in a pint and half of water, adding two ounces of oil, and as much common salt, given as a clyster, will seldom fail.

If doses of a grain or two of opium, repeated every six hours, fail to relieve, from 100 to 120 drops of the tinct. opii may be mixed with four ounces of warm olive oil, injected as a clyster; and repeated as often as the pain returns.

In case of a relapse, after the relief from purges, the medicines should be repeated; but the previous use of opium is unnecessary.

Fomentations and warm baths may prove auxiliaries, but no great dependence is to be placed on them. It is true, that while the patient sits in the warm bath the pain abates; but when he is taken out it returns. In this disorder, the pain must be allayed during some hours before the intestines will be disposed to perform their office; and few, if any patients can continue in the bath so long as ease is required. In general, as we have before mentioned, we think, we have found gangrene a more frequent consequence when the warm bath has been freely and frequently employed, than when it has been omitted.

Dr. Warren and Dr. Biss relate their success in attempting the cure of the *colica pictonum*, as it is denominated by one, and the dry belly ach by the other, by means of a salivation with mercury; and observe, that as soon as the ptyalism was perceived, the pain abated, and returned no more. One of these gentlemen observes, that in mild cases, where a salivation seemed not necessary, blisters applied to the upper and fore part of the thighs, near the groin, were sometimes effectual. Dr. Hugh Smith advises to apply the blisters on the belly.

Dr. Grashuis commends alum as a specific in this disorder: and Dr. Percival, in his *Ess. Med. and Exp.* relates the success which hath attended his use of this medicine in various painful disorders of the bowels. He gives it from gr. x. ad xx. every four or six hours; and a few doses, thus administered, never failed to procure relief, and, duly repeated, to effect a cure.

"In violent colics," remarks Dr. Percival, (*Med. Commentaries*, vol. v. p. 172.) "attended with vomiting and an obstinate constipation of the bowels, it has been the common practice amongst physicians to give opiates, in conjunction with purgatives. This method of treatment has been lately improved by administering the opiate first, and the purgative an hour or two afterwards. But I take the liberty of suggesting to you another mode, which, as far as my own experience extends, has proved the most successful. I directed three or four ounces of a strong decoction of poppy heads, with twenty, thirty, or forty drops of tinctura opii, to be injected into the intestines, and retained as long as possible. If it be speedily discharged, the clyster is repeated till the pain is relieved, and the vomiting ceases. A dose of calomel and jalap, or any other brisk cathartic, is then administered; and its operation quickened by the use of

sena tea, of a solution of the neutral salts, or of castor oil. By this process, evacuations are procured with more ease, certainty, and expedition, than by any other which I have tried. For opium, when given in a clyster, does not check the peristaltic motion of the intestines, nor counteract the operation of any purgative so powerfully as when received into the stomach. And, in this way, it is most efficacious in alleviating the sickness, and in putting a stop to the violent retchings, with which colics are often attended. The taste of laudanum is often so nauseous, that it is frequently rejected as soon as swallowed. And, if the extractum opii be given in a solid form, time must be allowed for its solution, before any effect can be expected from it."

On this subject we need scarcely repeat the remark, which we have had occasion to make, viz. that the opiate should be first given, and left to produce its full effects, before the purgative is administered; nor have we found the remark of Dr. Percival confirmed by practice, that opium in clysters is less constipating than by the mouth.

The palsy which remains after the removal of the colic is best relieved by the use of Bath water; but as the circumstances sometimes do not admit of this method, the whole length of the spine may be rubbed with Barbadoes tar, dissolved in rum; and such other antiparalytics may be used as the constitution of the patient, and other circumstances, may admit.

The third species, the *colica stercoraria*, arises in almost every instance, from a want of irritability in the bowels. In old people, it amounts to a paralytic torpor; and, though it may arise from calculi, yet this cause is exceedingly rare, and it is more often owing to palsy. It is then attended with no pain; and the disease scarcely admits of even temporary relief. The most active purgatives have no effect; and we gain little benefit from the warmest liniments rubbed on the spine, or into the abdomen. In younger persons it is removed by powerful cathartics: the oily ones have been preferred; but we have found the resin of jalap, combined with soap, the most successful.

The fourth and fifth species, *c. accidentalis* and *menconialis* require little comment. Manna, sweet oil, or a common clyster, easily relieve the latter: and any common purgative the former.

The *colica callosa* is the disease styled the *scirrhus contracted rectum*. The contraction is, however, beyond the reach of a topical remedy; and the disease is distinguished by the alternation of obstinate constipation, with a thin watery ineffectual discharge. It is a very rare occurrence; and the patient is usually left with little exertion in his favour. In a long practice, we have not seen more than four cases. Should another occur, we shall be tempted to employ a remedy some time since fashionable, mercury, divided by the extract of cicuta. If it is ever useful, which we doubt, the scirrhus contracted rectum may be relieved by it. The *c. calculosa* scarcely ever occurs in the human body.

*Colica flatulenta*. The FLATULENT COLIC is usually a symptom or consequence of some other disorder, and is neither accompanied with fever nor thirst; however, the pain is acute, as the seat of the complaint is in the small intestines. Cardialgic symptoms, with efforts to vomit, sometimes attend; and a costiveness is the consequence of the great distention.

It is frequently caused by wetting the feet, or otherwise checking the perspiration. Rubbing the legs with warm cloths, and afterwards keeping the feet for some time in warm water, will be the most effectual remedy.

When a person is subject to frequent returns of this disorder, it proves that the digestive powers are weak; and warm tonics are the most effectual remedies. The columbo root and quassia are, however, preferable to bark and cascarilla.

To promote the discharge of wind, clysters of warm water, with a large proportion of carui seeds, may be frequently repeated. Warm gums, as in the gum pill, are useful; and a solution of the asafœtida may be injected as a clyster. Warm camomile tea may be now and then drunk; and tincture of rhubarb, with a few drops of the oil of mint, will be occasionally necessary. Sometimes the conf. opiata, joined with rhubarb, gives speedy relief.

See Trochin on the Colica Pictonum, with Schomburg's Notes. Thierry on the Colica Pictonum. De Haen on the Colica Pictonum. Huxham on the Colic of Devonshire. Warren's Account of the Colica Pictonum, in the Lond. Med. Trans. vol. i. ii. Sydenham's Works, with Notes, by Wallis. Percival's Essays, Medical and Experimental, vol. ii. p. 194, &c. Medical Musæum, vol. iii. p. 579, &c. Cullen's First Lines, vol. iv.

CO'LICA SINI'STRA, and CO'LICA SUPE'RIOR, ARTE'RIA. See MESENTERICÆ ARTERIÆ.

CO'LICA VE'NA is a branch from the *meseraica vena major*, running from the anterior part of the trunk before it joins the artery, to the middle of the colon, where it divides to the right and left, and forms arches. On the left it communicates with the upper branch of the hæmorrhoidalis, and on the right with the second branch of the *meseraica*.

CO'LICA RE'CTA, VE'NA. It is a branch of the *gastrocolica vena*; it goes to the right portion of the colon, from thence to its upper part, where it divides, and anastomoses with the colica and the cœcalis.

COLIFO'RME OS, (from *cola*, a strainer, and *forma*, likeness; so called from having many perforations). See ETHMOIDES OS.

CO'LINIL. Called also *nil*; *Indigo spuria*; *polygala Indica minor*. *Convolvulus nil* Lin. Sp. Pl. 219. The name of an American plant, the juice of which, with a little honey, cures pustules in the mouth. Raii Hist.

COLI'PHIUM, (from *κωλον*, a limb, and *φι*, strongly). BOMPOURNICKEL. A sort of bread made of the flour and bran as it comes from the mill. It was made for wrestlers, and used by the Greeks, as more nourishing than bread. The Romans, for three hundred years, only made bread of this kind. In Norfolk and Westphalia, that sort of bread is now in use. Some of the most ancient nations called the bread thus made *panis furfuraceus*; (see Aulus Gellius, lib. ii. cap. 9). *Panis impurus*; (see Hippocrates.) Athenæus, lib. iii. calls it bread prepared of unsifted meal, *syncomiston*. Cælius Rhodiginus, lib. ix. c. 16. calls it *panis cibarius*, and *panis gregarius*; Terence, *panis ater*. The foundation of its nutritious quality we now understand, since the bran contains the gluten, which is of an animal nature.

COLLATE'NNA. A certain specific for the cure

of wounds. It is mentioned by Paracelsus in his work De Vitâ Longâ.

COLLA'TERALES, (from *con*, and *laterales*, on the same side). See ERECTORES PENIS.

COLLATI'TIUM, (from *colla*, glue, or jelly). A sort of food prepared, according to Blancard, of the flesh of a capon, or a pullet bruised, and then mixed with mutton broth, and eaten with verjuice, or lemon juice.

COLLE'TICA, (from *κολλα*, glue). Conglutinating or healing medicines. See COAGULANTIA.

COLLI'CIÆ, (from *colligo*, to collect). The union of the ducts which convey the humours of the eyes from the puncta lachrymalia to the cavity of the nose.

COLLI'CULA, and COLLI'CULUM. A diminutive of *collis*, a hill. See NYMPHÆ.

COLLIGA'MEN, (from *colligo*, to bind together). See LIGAMENTUM.

COLLIQUAME'NTUM, (from *colliqueo*, to melt). An extremely transparent fluid in an egg, observable after two or three days incubation, containing the first rudiments of the chick. It is included in its own proper membranes, distinct from the albumen. Harvey calls it *oculus*.

COLLIQUA'TIO. COLLIMATION, (from *colligo*, to melt away). A dissolving or wasting.

COLLI'SIO, (from *collido*, to beat together). See CONTUSA.

CO'LLIX, (from *κολος*, food). A sort of round loaf or cake; but in Hippocrates, and other Greek medicinal writers, *κολλιξ* imports a sort of pastil, or troche, of the form above mentioned. See TROCHISCI.

COLLO'DES, (from *κολλα*, glue). Glutinous.

COL'LUM, (from *columna*, the pillar and support of the head). See CERVIX.

COLLUTO'RIMUM O'RIS, (from *colluo*, to wash). See GARGARISMA.

COLLU'VIES, (from *colluo*, to wash or rinse, in its primitive sense means filth. In a medical sense, it is expressive of any corrupted or contaminated fluid.

COLLY'RIMUM, (from *κολλα*, glue, *ρεω*, flow,) as they were usually glutinous, or designed to dilute the glutinous discharges. Suppositories, tents, and other things, have been styled *collyria* from their form; but as they were used whole, or in their proper shape, they were called *entire*: what were called *collyria*, without the epithet *entire*, were finely powdered and applied to the eyes. At present, a *collyrium* only means a topical medicine for the eyes, called EYE WATER. It differs not from a lotion, but in the term and application.

*Collyria* made with vegetable infusions and salts that entirely dissolve are more elegant, and agree better with the eyes, than when they contain powders.

Hoffman condemns all acrid, astringent, cooling, drying, and mucilaginous applications to the eyes. Wedelius observes, that aloes relieves the eyes more than opium; but experience proves this opinion erroneous. After proper evacuations have preceded, two drachms of tincture of opium, mixed with two ounces of rose water, will very often produce considerable relief; or, in some obstinate cases, the tincture of opium may be used alone with success. The usual *collyria* are either sedative or astringent. The preparations of lead are of the former kind; those of zinc and copper are astringent: each is applicable in different states of the disease. See OPHTHALMIA.

COLLYRIUM CÆR'ULEUM. See CUPRI AMMONIATI AQUA.

COLOBO'MA, and COLLOBO'MA, (from *κολοβοω*, *to maim*;) the growing together of the eye-lids. Also a want of a particular member or part of the body.

COLOBO'MATA, (from the same). In Celsus, this word is expressed by *curta*. Both the words signify a deficiency in some part of the body, particularly the ears, lips, or *alæ* of the nostrils.

COLOCA'SIA, (from *κολος*, *food*, and *καζω*, *to adorn*; so called from its use as a food, and the custom of wearing its flowers in wreaths). See FABA ÆGYPTIA.

COLOCHIERNI CARDUUS CRETENSIBUS.

A plant which differs very little from the *atractylis*.

COLOCY'NTHIS, (from *Κολον*, *the colon*, and *κινεω*, *moveo*, from its active purging powers). BITTER APPLE. Also called *althandala*, *colocynthis medulla*, *coloquintida*. BITTER OR WILD GOURD. It is the dried pulpy part of a species of gourd; the *cucumis colocynthis* Lin. Sp. Pl. 1435. Nat. order *cucurbitaceæ*: differing from the common sort only in the leaves being deeper jagged, and the fruit not eatable. It is brought from Aleppo, and grows in many parts of Turkey. It is very light, white, and of a fungous texture, composed as it were of membranaceous leaves, with a number of roundish seeds lodged in the cavities.

The seeds are unctuous and sweetish, like those of cucumbers, but not purging: the fungous medulla, freed from the seeds, is acrid, nauseous, and bitter to the taste, and is a strong irritating cathartic. It is commended also, in less doses, as an alterative in chronic disorders. It is rarely used alone, though ten or twelve grains will purge violently, frequently producing violent colic, bloody discharges, and even disordering the whole system; but if mixed with other purgatives, it quickens their operation.

When boiled in water, it gives out a large quantity of gluten; to proof spirit it does the same: the watery decoction, inspissated to an extract, purges briskly, but with less irritation than the colocynth itself in half its weight. Mr. Bolduc thinks that the active matter resides in its salts, which far exceed the resin and the oil in quantity, and that water is its best menstruum. But the most effectual method of abating its virulence, without diminishing its purgative quality, seems to be by triturating it with gum, farinaceous substances, or the oily seeds; by which means its resinous particles are prevented from adhering to the membranes of the intestines, so as to irritate and inflame them.

COLOCY'NTHIDIS COMPO'SITUM EXTRACTUM. It is directed to be prepared by the London college in the following manner; viz. pith of coloquintida six drachms; aloes an ounce and a half; scammony half an ounce; lesser cardamom seeds one drachm; proof spirit a pint. Digest the coloquintida with the spirit for four days, with a gentle heat. To the extracted tincture add the aloes and scammony. When these are dissolved, draw off the spirit by distillation, evaporate the water, adding the seeds towards the end of the process.

CO'OLON, (from *κολον*, *hollow*). It is the first and most considerable of the large intestines, called also *enteron*. From the cæcum it reaches in the form of an arch above the umbilical region, and extends to the

lower part of the left hypochondrium, running down before the left kidney, to which it is connected, and below which it turns towards the spine; then forming two opposite convolutions, called the *sigmoid flexure*, it terminates in the rectum. When it has passed below the last vertebra of the loins to the inside of the os sacrum, it is bent backwards on the concave side, to which it is joined; and running in the direction of the os coccygis, bends a little forwards, and terminates in the extremity of that bone.

The continuity of the colon is a little interrupted by the intestinum ilium, which advances into the cavity of the colon; not at its extremity, but at the distance of about two inches, penetrating through its longitudinal fibres. It thus forms the valve of the colon, which is shut only when the colon is distended. From this structure, it is evident that no sphincter is necessary to prevent the fæces returning to the ilium: yet this sometimes happens from a retrograde peristaltic motion; and even clysters are thrown up by vomiting.

The whole convex side of the colon is divided longitudinally into three parts, by three ligamentous bands, continued from those of the cæcum, and of the same structure with them. Two of these bands run on each side along the great curvature of the colon, and the third along the small curvature. This last was first noticed by Morgagni. Between these ligaments the intestine is formed into cells, from the ligaments being shorter than the duct, called the *cells of the colon*. The cellular coat does not differ from that of the small intestines; the internal coat is not villous, but papillous; the rugæ are waved and irregular.

From the apparent course of this intestine, warm clysters may, it is said, be applied to almost all the abdominal viscera; for it begins under the right kidney, and runs up on its fore part, passes under the gall bladder, then runs upon the first curvature of the duodenum, to all which it is contiguous; from thence it runs before the great convexity of the stomach, then touches the spleen, and goes on to the left kidney, as above mentioned. This representation is, however, the offspring of theory and ignorance; for no clyster, except when thrown up by an injecting syringe of strong powers, furnished with a lateral pipe, can pass even the sigmoid flexure. De Haen, in this way, has sometimes filled the colon of a dog, and forced the valve; but he often failed.

The colon on its upper part receives arteries from the mesenterica superior and inferior: the lower portion is supplied from the mesenterica inferior, one of which forms the internal hæmorrhoidal artery. The veins are from the vena portæ ventralis, the meseraica major and minor, or hæmorrhoidalis interna. The nerves of the arch of the colon are the two mesenteric plexuses.

When pain is in the colon, it is less acute, and with a sense of weight; when in the small guts, there is not any sense of weight, but an acute pain. If fever attends pain in the colon, the pain extending to the ribs gives a suspicion of pleurisy, though the colon in reality is only affected. The colon is narrower in the right side than elsewhere, whence colic pains arise more frequently, and are more acute in this part. The excrements are long retained in the colon, and often much indurated before they pass on.

COLOPHO'NIA, (*Κολοφονία*, a city of Ionia, from

whence it was first brought). **COLOPHONY**, or **BLACK RESIN**; called also *berriouis resina fricta torta*, vel *nigra*; **DRIED OR BLACK RESIN**. *Phrycte* is used alone in this sense, as a distinction from the liquid sort called *hygra*. It is only resin whose humid and volatile parts are most dissipated. It receives its names as above from the city, which formerly furnished the best kind.

Two sorts are mentioned in ancient writings, the dry and liquid. The latter seems to have been liquid pitch, which is the crude resin of the pine brought from Colophon; the former was the *resina fricta*. The latter Greeks called every kind of resin colophony.

The best colophony is the resin of turpentine, which, after the ethereal oil is distilled, is again urged by a strong continued fire.

**COLOQUI'NTIDA**, (from *κολον*, and *κινεω*, *moveo*). See **COLOCYNTHIS**.

**COLORA'TUS**, (from *color*, *colour*). In botany it means varying from its usual colour, as when leaves which ought to be green are of the colour of the flower.

**COLORI'NDUS** is a mixture of blue and purple.

**COLO'STRUM**, (from *κολος*, *food*, because it is the first food of the young). The first milk of any animal, after bringing forth its young; that from cows is called **BEESTINGS**. It is thin, gently cathartic, and carries off the meconium; serving both as aliment and medicine.

An emulsion prepared with turpentine, dissolved with the yolk of egg, is sometimes called *colostrum*.

**COLOTOIDES**, (from *κολων*, *a lizard*, and *ειδος*, *likeness*). Variegated like the skin of a lizard. Hippocrates applies it to the excrements when of different colours.

**COLPOCE'LE**, (from *κολπος*, *sinus*, and *κηλη*, *hernia*). A hernia of the urinary bladder protruding into the vagina. Hence called *cystocele vaginalis*, or *clytrocele*. A patient had been for many years liable to violent hysteric affections, which at last were succeeded by a dry, convulsive cough. When this cough disappeared, she was seized with a suppression of urine, together with great pain and tenseness in the abdomen. When other remedies had failed, the catheter was employed; but with difficulty introduced. This suppression returned very frequently, was always preceded by the convulsive cough, and sometimes attended even with convulsions, which commonly ended in faintings. The obstruction which occurred to the introduction of the catheter seemed to proceed from a considerable weight and pain which the patient complained of in the fore part of the genitals, and which was always most severe when the suppression of urine was not considerable. On examining the parts, the hypogastric region was tense and painful, but there was no considerable tumour perceivable, as there usually is, in the under part of the belly, when the urine has been long suppressed; but, upon introducing the finger into the vagina, while the suppression continued, a large tumour was discovered, which occupied the whole cavity of the vagina. In this swelling a fluctuation was perceived, but no urine could be evacuated by compressing it, unless the catheter was at the same time introduced, and then a plentiful evacuation ensued; though, even in this manner, the contents of the swelling could not be entirely discharged, unless the compression was continued. When the urine was entirely evacuated, the catheter could be easily introduced; the tumour disap-

peared; the superior part of the vagina felt lax and flaccid; and the finger could be easily pushed up to the mouth of the uterus, till the tumour began again to increase, by the urine collecting in the bladder. Then the former symptoms returned; and were relieved, as before, by the catheter. The urine, which at first was of a natural appearance, after the disorder had subsisted for some time, became less pure, and seemed to contain a number of small membranous filaments, as if the internal coat of the bladder had been eroded. From this time the sensibility of the bladder became so much increased, that it was found necessary to introduce the catheter much more frequently than before. On considering the case, it appeared that a pessary, properly adapted for the support of the relaxed parts, would, in this case, probably be the most effectual remedy; and an instrument of that kind being procured, and so constructed as not to prevent the discharge of the menstrual flux, it was introduced; and being continued for several years, till the parts had again recovered their tone, a complete cure was at length obtained. The pessary was then no longer necessary, and the patient discharged her urine with perfect ease. See *Edin. Med. Comment.* vol. v. p. 257. *Sauvages' Nosol. Meth.* vol. i. p. 216.

**COLPOPTO'SIS**, (from *κολπος*, *the vagina*, and *πιπτω*, *to fall down*). See **PROCIDENTIA VAGINÆ**.

**COLPOS**. See **SINUS**.

**COLUBER BE'RUS**, (*quod colat umbram*, because he delights in a shade). See **VIPER**.

**COLUBRI'NA**, (from *coluber*, *a snake*; from the snake-like contortions of its roots). See **SERPENTARIA**, **DRACONTIUM**, and **BISTORTA**.

**COLUBRI'NA LUSITA'NICA**, **HE'RBA**. See **CAACTICA**.

**COLUMBRI'NUM**, (from *coluber*, *the snake*; *colubrinum lignum*, *radix colubrina*, *nux vomica minor moluccana*, vel *altera modira caniram*, *solanum aborescens Indicum*, **SNAKE WEED TREE**).

It is the wood of one species of the genus which affords the *nux vomica*, viz. *strychnos colubrina* Lin. Sp. Pl. 271. (See **STRYCHNOS**). It is brought from the East Indies in pieces about the size of a man's arm, covered with a brownish or rusty coloured bark, internally of a yellow colour, with whitish streaks.

It hath a faint but not disagreeable smell; after chewing for some time the taste is bitterish: it gives a gold colour to water and to spirit; affords a fourth of its weight of extract by means of spirit, but not so much by water.

It hath been given in doses of half a drachm, as an anthelmintic; in quartan agues and some other disorders. It operates differently, sometimes passing off by urine, at others by sweat, or by stool. In a less degree it displays the deleterious qualities of the *nux vomica*.

**COLUBRI'NUS LA'PIS**, or **SERPENTIS**. It hath its name from the snake *coluber*, from which it was thought to be taken; but it is now known to be an artificial composition. It is made of hartshorn, burnt to blackness, and afterwards polished; or of clay. It is fabled to be a cure for the bites of serpents, by applying it to the wound.

**COLU'MBAC**. See **AGALLOCHUM**.

**COLU'MBO**, **COLU'MBA**, **COLUMO'BE**, or, in the Portuguese language, *raijs de Mosambique*.

It is produced in Asia, from whence it was trans-

planted to Columbo, a town in the island of Ceylon, and from whence all the East Indies are supplied with it.

The plant is not known; but from a note in Commer-son's Herbal, it appears probable that it is a species of the *menispermum*, which he styled *palmated*, not known to Linnæus. It is bristled with hair, has leaves with five lobes, often palmated; the base at the heart and the lobes are often sharp pointed.

It is brought into Europe in circular pieces of different sizes, some of which are three inches diameter; its sides are covered with a thick wrinkled bark, of a dark brown hue externally; when cut transversely, they exhibit a large central disk, with brown streaks, and yellow points. The root consists of three laminæ; viz. the cortical, which in the larger pieces is a quarter of an inch thick; the ligneous, which is about half an inch; and the medullary, which forms the middle, and is near an inch in diameter. This last is softer than the other parts, and, when chewed, seems to be very mucilaginous. Many small fibres run longitudinally through it. The cortical and ligneous parts are divided by a circular black line.

It hath an aromatic smell, but is disagreeably bitter, and slightly pungent to the taste; is supposed to be almost a specific in the cholera morbus, nausea, vomiting, diarrhœa, bilious fever, indigestion, and most other disorders of the stomach and bowels. It is slightly sedative, corroborant, and antiseptic. The bark resists the putrefaction of animal flesh; and the root exceeds it in preserving the bile from putridity, or in correcting the putrescency which has already commenced. As it is not heating, it may be used in hectic fevers. A tincture of this root in brandy is a very useful remedy for moderating the retchings during the first months of pregnancy. Dr. Cullen says it is a strong and agreeable bitter, and he has employed it in many instances of dyspepsia with great advantage. In checking vomiting it has frequently succeeded; but he has found it to fail even where there seemed to be a redundancy of bile; nor, in correcting the acrimony and putrescency of the bile, has it appeared more powerful than other bitters.

It may be given in powder from ten grains to two drachms, but the common dose is from fifteen to thirty grains, every three or four hours; and in bilious cases it should be joined with an equal part of vitriolated kali. The powder has been applied to ulcers, which, by common remedies, cannot be brought to a healing state; and Mr. Home thinks it next in efficacy, for this purpose, to rhubarb; nay, when rhubarb begins to lose its effect, columbo will frequently renew the healing process, and ultimately be successful.

Distilled with spirit, it sends over little of its taste or smell; but the extract, made by evaporating its decoction in rectified spirit of wine, is better than the root itself in powder: about two thirds of this root is obtained in the spirituous extract.

The London college order the following preparation of the TINCTURE OF COLUMBO: Take of columbo root, powdered, two ounces and a half; proof spirits of wine, two pints; digest for eight days, and strain: one or two drachms, or more, may be taken repeatedly in mint water, or in an infusion of orange peel: the last renders it the most grateful. It powerfully and

speedily relieves those colic pains which arise from flatulence or indigestion.

The EXTRACT OF COLUMBO ROOT is made by digesting twelve ounces of columbo root in powder four days, in three pints of rectified spirit of wine. After filtering this tincture, the residuum is boiled repeatedly in different waters, until it yields little or no taste to the liquor. The decoction is then strained and evaporated until six pints only remain: this is evaporated in a vapour bath: and, when nearly finished, the tincture is added, and the whole reduced to the consistence of a pill.

See Cullen's Mat. Med. Percival's Essays Medical and Experimental, vol. i. ed. 2. Notes to Sydenham by Wallis, vol. iv. p. 221.

COLUME'LLA, (a dim. of *columna*, a column; so called from its shape). The *clitoris*, also the *uvula*, and *hypostaphile*, or falling down of the uvula. See also CAPSULA.

CUMELLA'RES DE'NTES, (from *cumella*, on account of their shape). See CANINI DENTES.

COL. ET COLUM. ECPH. An abbreviation of Fabii Columnæ minus cognitarum rariorumque stirpium Ecphrasis, 1, 2. Romæ, 1616, 4to.

COL. ET COLUM. PHYT. An abbreviation of Fabii Columnæ Phytobasanos sive Plantarum aliquot Historia. Neap. 1592.

COLUMNA O'RIS. See UVULA.

COLUM'NA NA'SI. The lowest and fleshy part of the nose, which forms a part of the septum.

COLU'MNA SEPTI PA'LATI. See PALATUM MOLLE.

COLU'MNÆ. Many parts of the body which, in their shape or orifice, resemble columns, viz.

COLU'MNÆ. See CARDUUS PINEÆ.

COLU'MNÆ CO'RDIS, vel CARNE'Æ. These are small, long, and round fleshy productions from the ventricles of the heart. According to Le Dran, the basis of the heart is also thus named. See COR.

COLUMNIFERUS, (from *columna*, a column, and *fero*, to bear). An order of plants bearing columns or pillars.

COLUTE'A, (from *κόλλω*, to mutilate; so called because it perishes if any of limbs are cut off;) *senna pauperum*, *colutea vesicaria*, *senna Mauritanorum*, *senna Europea*, *senna spuria*, BASTARD SENNA. *Colutea arborescens* Lin. Sp. Pl. 1045.

It is a bush whose flowers are succeeded by large, swelled, thin bladders, flattish on the upper part, sharper and carinated underneath, with a crooked appendix at the end, full of black kidney-like seeds. It grows wild in Italy, and flowers in July. The leaves and seed purge and vomit violently; but it is scarcely found in the lists of the materia medica.

COLUTE'A caule genistæ fungoso. See POLYGALA VERA.

COLUTE'A I'NDICA HERBA'CEA. See INDICUM.

COLUTE'A SCORPIOIDES, MA'JOR, HU'MILIS, et SILIQUO'SA. See EMERUS.

COLYMBA'DES, (from *κολυμβάω*, to swim). Olives pickled in salt, or *swimming* in their own oil.

COLYMBE'THIRA, (from the same). See DEXAMENE.

COLYTE'A. See SILIQUASTRUM.

CO'MA, (*κομη*, a head of hair). The hair of the head. In botany, a species of bracte, terminating the

stem in a tuft, or bush. A spike of flowers terminating by a coma is called *comose*. And plants with such flowers are ranged in the thirty-sixth of the natural orders of Linnæus' *Philosophia Botanica*.

CO'MA, (from *καω* or *κωω*, to lie down). In Galen's *Exegisis* it is expounded by *cataphora*; and in his treatise on a coma, he says, that coma includes every *cataphora*, both the sleepy and wakeful. By the word coma the author of *Prorrheticon* often expresses a lethargy. The coma is sometimes called by the name *typhomania*, being supposed to consist of a mixture of phrensy and lethargy. It is the coma *somnolentum* of authors; in reality, a less violent degree of apoplexy, in which the loss of sensation is not so considerable. See CAROS.

CO'MA AU'REA. GOLDEN LOCKS, also GOLDEN CUD-WEED. See ELICHRYSUM.

CO'MA VI'GIL; called also *agryphnocomia*. A disease wherein the patients are apparently sleepy, but can never sleep. Blancard. See CAROS.

COMARO'DES, CO'MARUS, (from *καμη*, a lock of hair; so named from its strings, which are like hair). See ARBUTUS.

CO'MATA. See COMA. The first order of Dr. Cullen's second class *neuroses*; defined a diminution of voluntary motion, attended with sleep, or a deprivation of the senses. In this order he ranks APOPLEXIES, PALSIES, and adds the species of TREMOR. He therefore comprehends those affections which have generally been called *soporose diseases*; but observes, that they are distinguished by consisting in some interruption or suppression of the powers of sense and voluntary motion, or of what are called the animal functions. These, he observes, are usually suspended in the time of natural sleep; but in all these diseases, sleep, or even the appearance of it, is not constantly a symptom. They are also termed *nervorum resolutiones*.

COMBINATION OF MEDICINES. In the rage of reformation, it is not uncommon to step beyond the proper limits; and, in almost every science, it is necessary, in different eras, to review dispassionately the conduct of its professors; to correct, at times, their intemperate zeal, or to supply their omissions. Physicians have for many years aimed at simplicity in prescription, with propriety and success; but they have sometimes failed, in wholly rejecting combinations with which their ancestors succeeded. And it was rather a spirit of empiricism than philosophical induction which gave a general currency to Dover's sweating powder, and many of Ward's compositions.

To check, in some degree, the rage of simplicity, and the general tendency to too great refinement, we shall, from the different classes in medicines, select some instances, where combination is not only defensible but advantageous. We have already hinted at this subject under the head of CATHARTICS, and pointed out the paper of Dr. Fordyce on the same subject. Though we may employ some of his instances, we shall not servilely follow his steps; but in the principal part of this article follow a different direction.

In the exhibition of *emetics*, we are often disappointed, by the medicine remaining inactive in the stomach, and escaping, with its stimulant powers unimpaired, into the intestines. The addition of an antimonial to the ipecacuanha may quicken its action; but this is subject to a similar inconvenience. By the addition of a few

grains of the white vitriol, we can often, with either of the others, produce the effect. A sedative emetic, less dangerous than the tobacco or the foxglove, would be a great acquisition to the materia medica; but, even at present, in some pulmonic cases, the foxglove may be actively given for this purpose. The union of the squills with the ipecacuanha has often been highly useful, and equally so with the antimonials.

In the class of *cathartics*, combination is often essentially necessary. We have distinguished cathartics as operating by increasing the secretions from the glands of the chylipoietic viscera, and thus affording the natural stimulus to the intestines; as increasing the action of their moving fibres, by a stimulus peculiarly their own; or, as occasioning an extraordinary effort of the constitution, to throw off a poisonous substance introduced. It will be obvious, by uniting the two first, we gain many advantages. The effect of rhubarb, for instance, will be quickened and increased, if the polycrest salt assists in increasing, at a more early period, the motions of the alimentary canal; soap will sheath the acrid particles of aloes, and extract of jalap, while it assists their action; and the warmer gums, as in Dr. Fordyce's formula, gently stimulate the superior part of the canal, while they sheath and mitigate the too great acrimony of some of the ingredients. The old formulæ of manna with the salts, quickened by some of the more active tinctures, or occasionally with metallic preparations, though apparently a disagreeable and discordant union, had many advantages, which are, in vain, expected from the more elegant formulæ of modern times. In general, the more gentle laxatives should be quickened by the more powerful purgatives; and the latter (if indicated), softened by the oily, saccharine, the mucilaginous, or the saponaceous cathartics. There is, perhaps, no class of medicines in which greater latitude of combination may be allowed with advantage.

The subject of *diaphoretics* we must not anticipate; yet in this a judicious combination produces the most singularly beneficial effects. Generally speaking, the fluids are thrown to the surface by the stimulus of warmth, or other powers exciting the action of the heart and arteries. This stimulus, however, requires regulation; for we have found (see COLD), that excess of temperature is unfavourable to the discharge from the skin. Stimulus, when fever is not present, will, however, often succeed; but, in general, it requires the addition of a relaxant. Thus opium has, in every age, been the chief ingredient in sudorifics. But Dover refined on the former plans, by adding another relaxant; Ward, by the union of the white hellebore, which he, perhaps, supposed to be a stimulant, but which acted probably in a different way. Some poisonous medicines, by exciting nausea, relax the skin, and prove diaphoretic. Of this kind is the veratrum album, which Ward employed; and all the variety of narcotic vegetables will produce the same effect. In combination with the warmer stimulants, therefore, a great variety would probably form useful diaphoretics, did we want any more powerful than those we possess.

*Diuretics* are of a similar nature; and, independent of the more immediate and active stimulus conveyed to the kidneys, narcotics, by inducing general relaxation, promote greatly the flow of urine. Some combinations of the two kinds we have employed with effect; and, if

Bacher's tonic pill is useful, it is from a combination of this kind. The necessity of the union is sufficiently perceived, by joining aromatics with the foxglove. Why not rather the oils of juniper or turpentine?

*Errhines* are also of two kinds, the stimulant and evacuant: these are usually combined. We have but one internal sialogogue: but the Hindoo unites the stimulant with the sedative in the preparation of his betel.

In the exhibition of *emmenagogues* we occasionally combine with advantage, the more general stimulants and tonics with the topical stimulants of aloetic purgatives; sometimes the latter with relaxants: and, under *lithontriptics*, we have mentioned the union of the bitters, designed to counteract the calculous diathesis, with medicines that act on the calculus itself. We have even expressed our doubts, whether refinement has not too far simplified the medicine of Mrs. Joanna Stephens.

Medicines of a more general action do not so frequently require combination. We allude to *stimulants* and *sedatives*. *Astringents* and *tonics*, however, demand a more exact attention, properly to appropriate the medicine to the disease, as each is seldom without an admixture of the other, and a stimulant principle is sometimes combined. But this part of the subject requires a minuteness of detail, which can only be advantageously pursued when connected with the consideration of separate diseases.

In many of these classes, Dr. Fordyce seems to think, that the union of two or more substances of the same class can be more easily borne, and be more effectual, than the same bulk of a single medicine; as water, when saturated with one salt, will dissolve a portion of a different kind. It is not improbable; and while, as in the classes just alluded to, we are measuring the degree in which we shall add the warmer to the purer astringent, we may perhaps increase the activity of the medicine. On this subject we cannot properly decide; for *we*, too, are of "St. Thomas, and hard of belief."

Another method in which combination will be useful is, where two indications can be at once answered by the union of different medicines. The instance given by Dr. Fordyce is the union of tormentil with ipecacuanha in old diarrhœas. The one strengthens the bowels, while the other determines to the skin: an effect highly advantageous in the cure. This consequence of combination is peculiarly important, and we would strongly recommend it to the practitioner's attention: but it will be obvious, that it rather relates to the management of particular diseases; and to pursue the subject would require a volume. See *Transactions for improving Medical and Chirurgical Knowledge*, vol. ii. p. 314.

COMBU'STIO, and COMBUSTURA, (from *con* and *uro*, to burn). See CALCINATIO.

COMEDO'NES, (from *comedo*, a glutton). A sort of worms, which eat into the skin and devour the flesh. See BOVINA AFFECTIO, and CRINONES.

COME'TES, (from *κωμη*, a bush of hair; so named from its appearance). See AMYGDALOIDES.

COME'TZ. HALF A DROP.

COM'SDI. See GUMMI ARABICUM.

COM'STE, (from *κομίζω*, to provide). FOOD, NOURISHMENT.

COMITIA'LIS MORBIS, (from *comitia*, an assembly). See EPILEPSIA.

COMITISSÆ PULVIS, (from *comitissa*, a countess). See CORT. PERUV.

COMITISSÆ PALMÆ, or PALMERI PULV. See MAGNESIA ALBA.

COMMAGE'NUM, (from *Commagene*, a place in Syria, from whence it was brought). The name of an ointment mentioned by Galen. It is also called *Syriacum unguentum*.

COMMANDUCA'TIO, (from *commanduco*, to eat). See MASTICATIO.

COMMA'NSUM, (from *commando*, to eat). See APOPHLEGMATICA.

COMMEL. PLANT. USU. An abbreviation of Caspari Commelinis Horti Medici Amstæledamensi, Plantarum Usualium Catalogus. Amstel. 1724.

COMMEL. PRÆLUD. An abbreviation of Caspari Commelini Præcludia Botanica, Ludg. Batav. 1715.

COMMEL. FLOR. MAL. An abbreviation of C. Commelini Flora Malabarica, sive Horti Malabarici Catalogus.

COMMEL. INDIG. An abbreviation of Casp. Commelini Catalogus Plantarum Indigenarum Hollandiæ.

COMMENDATO'RIMUM (BALS.) (from *commendator*, the commander). The balsam of the commander of Berne, Balsamum Traumaticum, now *sinctura bezoës composita*. See BENZOINUM.

COMMINU'TIO, (from *comminuo*, to break in pieces). COMMINUTION. *Contritio*. It is the reduction of any solid body into finer particles, and is of two kinds, viz. CONTUSION, or PULVERISATION, and LEVIGATION, or TRITURATION; which differ, however, only in degree.

Subsequent to pulverisation, where extremely fine powders are required, two secondary processes are necessary, viz. searching and elutriation: the first is the passing of any pounded matter by agitation through the interstices of cloth of different fineness, stretched across a cylinder, covered with a similar one. The latter is by diffusing the powdered substance in a proper quantity of water; then decanting the liquor with the lightest part of the powder, as directed in the preparation of crude antimony.

In powdering any substance, care should be taken to accommodate the substance to the instruments: such medicines as will dissolve metal should be prepared in stone or glass mortars; very hard bodies will abrade soft marbles: to prevent then the mixture of the instruments made use of with the medicine that is prepared by them, such mortars, stones for levigating on, must be chosen, as cannot be affected by the uses they are employed in.

Light dry substances, resins, roots of a tenacious texture, are more easily pulverised if the mortar is previously rubbed with oil; camphor and cortex require a little water: tough substances may be grated or rasped: hard minerals, as flint, calamine, or stone, should previously undergo an extinction; that is, should be made red hot, and then quenched in water; the alkaline and calcareous stones should be converted into lime by this process.

Some metals, if heated to a proper degree, are rendered brittle, and then by agitation are easily powdered: of this kind is tin. This comminution of metals is called *granulation*.

Simple as this pharmaceutic operation is, its importance is considerable in medicine; resinous purgatives, when well triturated, are more easily soluble in the animal fluids, and operate more briskly with less irritation: antimony, finely powdered, discovers but little efficacy; but exquisitely levigated, is said to be a powerful alterative. Mercurials, and many other medicines, owe their virtue in part to comminution.

Roots, and such other articles as consist of different parts, viz. a resinous, ligneous, &c. should be completely powdered, and then the whole powdered substance should be well mixed together; for, without this precaution, one part which yields more easily to the pestle than another, as more friable, will be too active, and another too inert.

In levigating, some fluid must generally be added. Earthy and other hard bodies, that are not soluble in water, must first be finely powdered in a mortar, then levigated with water on a hard marble stone, and afterward dried on a chalk stone. Bezoar should be levigated with spirit of wine.

COMMISSU'RA, (from *committo*, to join together). See SUTURA, and ARTICULATIO. This term is also applied to the apparently fibrous structure which unites different portions of the base of the brain.

COMMISSU'RES, (from the same). See LABIA PUDENDI.

COMMO'SIS, (from *κομμι*, *gluten*). The first stratum of gummy matter with which bees line their hives. It also signifies that art which is employed in concealing natural imperfections with respect to beauty; from *κομμιω*, *ornatum adhibeo*. This is distinguished from the cosmetic art, which consists in preserving the beauty that is natural.

COMMUNICA'NTES FE'BRES, (from *communico*, to participate). According to Bellini, they are two fevers which infest a person at one and the same time, the paroxysm of one beginning as soon as the other ceases.

COMMUNIS SAL. See MARINUM SAL.

COMO'SE. See COMA.

COMPA'CTUS, (from *compingo*, to put together). In botany it means being of a firm and close texture.

COMPA'SSIO, (from *compatior*, to suffer with). COMPASSION. In nosology it is the suffering of one part on account of an affection of some other part: more commonly called suffering by consent, or *sympathy*. See SYMPATHIA.

COMPE'BA, and COMI'PER. See CUBEBA.

COMPLE'XUS, (from *complecto*, to comprise). Called also *trigeminus*. This muscle runs obliquely, rising from the transverse processes of the six inferior cervical vertebræ: and sixth, seventh, or eighth superior dorsal vertebræ: it then directs its course upwards, and is inserted into the cavity, below the transverse line of the occiput, and bends the head back. It sometimes receives a few slips from the spinal processes of some of the vertebræ of the dorsum. The complexus being removed, we see the two recti and the two obliqui.

COMPLE'XUS MI'NOR, called also *mastoidæus lateralis*, *trachelo-mastoidæus*, et *capitis*, *par tertium Fallopii*. When the splenius muscle is removed, we see the *complexus* and the *complexus minor*; the complexus is nearer the spine, and the complexus minor is under the upper edge of the splenius; it is various in different bodies.

Albinus describes its origin twelve different ways: it rises from the transverse processes of the three uppermost vertebræ of the back, and from the five lowermost of the neck, where it is connected to the transversalis cervicis, by as many thin tendons, which unite into a belly, and run up under the splenius. It is inserted into the middle of the posterior side of the mastoid process by a thin tendon. Its use is to assist the complexus, but it pulls the head more to one side. Innes.

COMPOSI'TUS, (from *compono*, to compose). In botany it means compound, aggregate, in opposition to single. In pharmacy a more complicated preparation of a common medicine.

COMPREHE'NSIO, (from *comprehendo*, to understand). See CATALEPSIS.

COMPRESSIO, (from *comfiremo*, to press upon). See CERE'BRI COMPRESSIO.

COMPRES'SOR NA'RIS. See NASALIS.

COMPU'NTIO, (from *comungo*, to prick). See PARACENTESIS.

CONA'RIMUM, (from *κωνος*, a cone). The PINEAL GLAND; so called from its shape. See CEREBRUM.

CONCAUSA, (from *con*, with, and *causa*, a cause). A cause which co-operates with another in the production of a disease.

CONCENTRA'TIO, (from *con*, and *centrum*, the centre). CONCENTRATION. To concentrate a body is to approximate its principal parts by removing those which keep them asunder, and which are not proper to the body concentrated. This word is generally applied to the dephlegmation of acids, and particularly of the vitriolic by distillation, of vinegar by congelation, and of salts by evaporation.

CONCE'PTIO, (from *concipio*, to conceive). Conception may be perhaps defined the first animation of the ovum, at the moment when it escapes from the ovarium, passing through the Fallopian tube to the uterus. The definition, which is undoubtedly connected with a theory, will be further illustrated under the article GENERATION, q. v.; but it is sufficiently supported by the weight of evidence. It is only necessary to observe in this place, that the ovum is very probably a part of the mother's system; that it has not life while in the ovarium, and that in every part of the progress pointed out, a living full grown fœtus has been found.

But, however secretly conception is effected, its symptoms are soon conspicuous. These consist in a preternatural irritability of the whole system, particularly of the stomach. Vomiting frequently occurs, after a few weeks, in the morning, and often incessant through the day. For some months nothing is seemingly retained in the stomach, and yet the child grows, though the mother is often greatly reduced. The whole nervous system is equally disturbed, and fancies the most strange and incoherent often agitate the mind. See PREGNANCY.

See Malpighius, De Graaf, Harvey, and Hamilton's Outlines.

CONCE'PTUS, (from the same). The very first rudiments of the fœtus in the uterus after conception.

CO'NCHA, (from *παρα το χανειν*, from its gaping). A SHELL. Some confine this word to the shell, while others intend by it the animal with its shell.

Sea shell fish, when boiled, are wholesome food, though supposed to be alkaliescent; their shells are

absorbent; if calcined, they become a quick lime, possessing all the properties of pure calcareous earth.

CO'NCHA ANATI'FERA, (from *anas*, a duck). Shell-fish, ridiculously supposed to produce a species of duck.

CO'NCHA AURI'GULÆ. See AURICULA.

CO'NCHA CYTHERIA'CA, CO'NCHA ERYTHRÆ'A. See CONCHIA VENERIS.

CO'NCHA MARGARITI'FERA. This word belongs to every shell fish in which pearls are found; but because the best pearls are found in the East Indies, it is confined for the most part to the *concha Indica magna*, whose shells are moderately hollow, thick, and externally of a yellowish colour, rough, uneven, and not striated; internally they are smooth, and shine like pearls. It is a species of oyster, principally found in the Persian sea, and is eaten raw or roasted. The shell of this fish is the *mater perlarum*. It is also called *cochlea margaritifera*. See MATER PERLARUM.

CO'NCHA STRI'ATA. The COCKLE. This is a shell fish employed as a nutriment, but being of a firmer substance than the oyster, is not so easily digested: in other respects it possesses nearly the same properties. See OSTREA and ALIMENT.

CO'NCHA VENE'NIS, or ERYTHRÆ'A. VENUS'S SHELL, is an univalve wreathed shell, having a small longitudinal and denticulated chink or aperture in it. It is also called *concha porcellana*, from its aperture resembling the mouth of a hog; and *concha cytheriaca*, from Venus, or its being found in the island Cythera.

As a medicine, for this shell the cockle or any other shell may be substituted; but it is now never demanded.

CO'NCHA. A liquid measure among the Athenians, which contained half an ounce; from three to five spoonfuls; in fact, nearly six drachms. Galen says, that the *concha magna* was the same as the *acetabulum*, which of liquid contained an ounce and a half, and in weight fifteen drachms; and that the *concha minor* was half an ounce of liquid, and five drachms of weight. It is a term applied also to some of the smaller and shallow cavities of the body.

CON'CHÆ NA'RIMUM INFERIO'RES; *convoluta inferiora, laminæ spongiosæ inferiores*. THE INFERIOR SPONGY LAMINÆ OF THE NOSE. They are situated in the nasal fossæ, one on each side; suspended like the ethmoidal concha, without resting on any thing. The inferior edges are the most considerable of the three; they are rough, thick, a little rounded, and turned toward the os maxillare. By their anterior superior edge, they are joined to the anterior transverse eminences of the os maxillare; their posterior superior edge is the longest, and is joined backwards to the small transverse eminence of the middle portion of the os palati. See Winslow's Anatomy, and Monro on the Bones.

CON'CHÆ NARIUM SUPERIO'RES; *convoluta superiora ossa, and laminæ spongiosæ interiores*. So Winslow calls the inferior part of each lateral portion of the os ethmoides.

CONCHARUM ANTIFEBRI'LE. Muscle shells are macerated in vinegar for twenty-four hours, after wiping off the external mucus. They must then be dried and reduced to a powder; during which operation a spoonful of carduus water, to prevent the light parts from

flying off, is added. A drachm is the proper dose as a febrifuge and diaphoretic. Bate's Pharmacopœia.

CONCHIFO'LIA, (from *concha*, a shell, and *folium*, a leaf; from its bearing leaves bent in the form of a shell). See MANGA.

CON'CHIS, (from *κογχη*, a shell). Among the Romans it is an entire bean wrapped up in its perfect capsule.

CONCHY'LIA FOSSI'LIA, (from the same). FOSSILE SHELLS. They are ridiculously supposed to be lithontriptic, because other shells when calcined are of that nature.

CONCHYROI'DES. See CORACOIDES PROCESSUS.

CONCIDE'NTIA, (from *concido*, to decay). A decrease of bulk in the whole or any part of the body, or the subsiding of a tumour.

CONCOAGULA'TA, (from *con* and *coagulo*, to coagulate together). The confused concretion, or crystallization of different salts, first dissolved in the same fluid.

CONCO'CTIO, (from *concoquo*, to digest). CONCOCTION. It is generally understood to be such a change upon the morbid matter, by the power of nature, generally with assistance of art, as renders it fit for separation from the healthy parts of our fluids, and to be thrown out of our bodies. But this doctrine, at least in fevers, is certainly false. That morbid matter, when it exists, passes off from the blood in its pristine state, appears from the matter of the small pox and measles, both which communicate the same disease at every period after the eruption. It is most probable also, that, in every infectious fever, the morbid matter, after assimilating some of the fluids of the patient affected, passes off in the same state that it was received. Acrimony in the blood is in no case rendered mild by any process in our constitutions: on the contrary, it is always expelled unaltered by some of the emunctories. Pus is never formed of a kindly nature whilst the heat of the body much exceeds the degree that is proper to health.

The theory of concoction, however, which has prevailed since the days of Hippocrates, has been of the most fatal consequence to the science of medicine, and to patients affected with fevers. It precluded all observation of the effects of medicines in the early stages of such fevers, and left the patient to the ravages of their cause. When the idea was added, that heat was the instrument by which the change was effected, the miseries of the sufferers were greatly augmented. The curtains were drawn; the windows shut; the fires large and incessant; and the medicines of the most stimulating kind. It was truly said, that those who recovered escaped *δια πυρός*, through the fire.

Sydenham supposed that the concoction of the febrile matter meant no more than a preparation and separation of the morbid from the sound particles. See Kirkland on Fevers, p. 14, 27.

CONCREMA'TIO, (from *con* and *cremo*, to burn together). See CALCINATIO.

CONCRE'TIO, (from *concreresco*, to grow together). In chemistry it is the condensation of any fluid substance into a more solid mass, importing the same as coagulation. In surgery it is the growing together of any parts which are separate in a natural state.

CONCU'RSUS, (from *concurro*, to meet together). See SYNDROME.

CONCU'SSIO, (from *concutio*, to shake together). A CONCUSSION. A jolt or shock in consequence of blows or falls.

CONCUSSION OF THE BRAIN. An affection of the brain, produced by a violent shock, without a wound or fracture, though it must have been often the subject of observation, has been but lately distinguished with accuracy. It has been confounded with the effects of depression and extravasation; with inflammation and abscess of that organ. The two latter are often its consequences; but should be clearly distinguished in the origin. To take the simplest idea of the disease, we will suppose a cannon ball to pass near the head. The person falls insensible: if it passes near the spine, death, or a paralysis of the lower limbs, is often the consequence. From this there can be no organic injury; none can be traced by dissection: and though the momentum of the air may account for the fall, it will not explain the subsequent disease. This, however, will be a future consideration.

In concussion, the greater number of symptoms which distinguish compression are present. The great distinction is, that the pulse is soft, often weak, and sinks on bleeding. A discharge of blood from the nose or ears, and the apoplectic stertor, are wanting. After a short period has elapsed, the insensibility in concussion is not so great: the patient will complain on the head being moved. The muscles retain their natural tone, and the pupils are often contracted; they are, indeed, sometimes dilated; the insensibility is then extreme, and concussion and compression often so much resemble each other, that they cannot, perhaps, always be distinguished. What adds to the difficulty is, that after the insensibility from the simple concussion begins to wear off, inflammation often comes on; not active inflammation, with violent pain and delirium, but the milder kind, from a dilatation of the vessels, exciting, in consequence, a slight increased action. This, in many cases, unsuspectingly runs its course, till symptoms of compression come on; and, after death, an abscess is found generally at the base of the brain, though, occasionally, in other parts of that organ.

The best foundation of the distinction in these very difficult emergencies is the effects of remedies. In every accident of this kind, blood should be taken. If there is no wound, if there is no evidence of an actual blow, it should be taken sparingly. Should the pulse sink, the insensibility continue, we must content ourselves with injecting a clyster, and consider it to be a concussion. Should, however, any blow be discernible; should the patient, on pressing the cranium on every part, show more sensibility when pressed on one rather than any other part; should the pulse *not* sink on a moderate bleeding; we have reason to think the accident has produced a fracture or an extravasation.

Concussion is a disease similar to the effect of insolation, an affection of the nervous aura, equally produced by noxious vapours, by the simoon of the desert, particularly by lightning or electricity, which probably produce their effects only by the momentum communicated to the air. Why this concussion of the air should affect the nervous aura it is impossible to say, until its nature is better known. Shocks, however, of every

kind produce, in different parts of the body, similar effects. How often will a fall in old persons occasion infarctions or abscesses in the liver, independent of any topical bruise, or obvious inflammation! By such concussions the vessels are weakened, and admit of congestion: the load is greater than the debilitated powers can overcome, and suppuration is the consequence.

In cases of concussion, our conduct is by no means cleared from difficulties. When the pulse sinks from bleeding, and when we are satisfied, from the other symptoms, that no depression or extravasation has taken place, the warmest cordials have been ordered. Yet, as we have a second stage to dread, they should be employed with caution. Evacuations by clyster, topical discharges from the head, not, with the hasty rashness of some modern practitioners, *at once*, but in a gradual manner to keep up a constant effect, and prevent too great a stimulus in the early period, are necessary. We may, for instance, apply immediately leeches; but not more than four. At this time, a blister at the nape of the neck may be operating. After its discharge has begun, two may be applied behind the ears; and, after a similar interval, another to the vertex. During this period, the bowels should be kept moderately open; wine and nourishment supplied in sufficient quantities to support the strength, and preserve a vital warmth, without heating. The extremities should be kept warm by friction, and hot bricks, if cold.

Mr. Bromfield was led, seemingly by a happy accident, to give the Dover's powder; for which he afterwards substituted an antimonial with opium. When we consider the extent of the vessels over the whole surface of the body, and recal to our recollection the advantages we derive from an evacuation from the skin in every topical congestion, we shall at once see the foundation of this practice, which, in his and other hands, has been found very successful. In reality, we consider it as one of the greatest improvements in modern practice; and, from the views we have given, the foundation of its use is particularly explained. Time, however, can only perfect the cure. The functions of the brain, if not hurried out of their regular train, exerted with too much energy, or too early, gradually recover, and the patient, at last, regains his former health: the time, however, is usually long.

If the patient has been neglected, or the plan not fully answered its intended purpose, though he appears to recover, yet, at an uncertain interval, shiverings, a low delirium, with marks of compression, come on. An abscess has then taken place, and death is inevitable.

Mr. Pott, in his description of concussion, has not distinguished sufficiently between the effects of the shock and extravasation; and Mr. Dease, though he approaches nearer to an accurate view of the subject, still confounds the two diseases.

From Mr. Schmucker's view of the cause of the disorder, is suggested the idea of astringent applications; and he informs us, that he employed them with the greatest advantage. The following he seems to prefer: R. Aq. pur. ℥ x. acet. acerrim. ℥ i. sal. nitri ꝑ iv. sal. ammon. crud. ʒ ij. m. With this embrocation he orders the part affected to be frequently well bathed; at the same time that blood letting is prescribed, together with the internal use of nitre, stimulating injections, and laxatives. In all the slighter affections of the head, the

greatest success, he says, has been observed from such a course; and, even in those which have required the trepan, Mr. Schmucker thinks he has often seen it employed with advantage. In concussions of the brain, even without any external wound, cold epithems and fomentations, he says, are very serviceable, especially if conjoined with stimulating clysters, and the application of leeches to the temples. Mr. Schmucker further observes, in the same work, that violent concussions of the brain are often produced merely from the passage of cannon balls near to the head, without any external affection being observable. In such cases, and in all similar concussions, emetics, he says, are commonly attended with the best effects; venesection, however, must always be premised.

See Berengarius de Commotione Cerebri; Mons. Bertrandi's Dissertation on the *Concussion* of the Brain, in the 3d vol. of the Memoirs of the Royal Academy of Surgery; Wiseman's Surgery, book v. ch. ix. obs. x. Gooch's Cases and Remarks, ed. 2. and Bromfield's Chirurgical Obs. and Cases, vol. i. ch. i. Dease's Obs. on Wounds of the Head; Pott's Works; Bell's Surgery, vol. iii. page 132. Abernethy's Surgical Essays.

**CONDENSA'TIO**, (from *condenso*, to make thick). **CONDENSATION**. It implies a contraction of the cutaneous pores by means of cooling, drying, or astringent medicines. It is also an inspissation of any fluid; *condensantia medicamenta* are such as authors have fancied possess a power of inspissating the fluids.

**CO'NDER**. See **OLIBANUM**.

**CONDIMENTUM**, (from *condio*, to preserve). *Artyma, conditura*. A **CONDIMENT** or **PRESERVE**. It signifies whatever procures sweetness and a grateful taste to any substance. But, in a more restrained sense, that is called *condimentum* which is used in preparing aliments, whether with an intention of rendering them palatable, or assisting their digestion.

Condiments make so considerable a part of modern luxuries, that a more particular consideration of the poignant substances employed to give a relish, which health and hunger have denied, becomes necessary. We mean not to say that every condiment is designed to give an artificial appetite. Spices in the warm climates are essential to health; and salt in every climate seems to be the same. But we must be more particular.

The condiments employed are those used to preserve meat from putrefaction, and those added occasionally in the process of cooking, or at table. Of the former kind, some merely preserve animal food without adding to the poignancy of the taste, as ice, vinegar, or a few pepper corns. Others give a poignancy, and alter the quality of the food, as salt, sugar, nitre, and smoke; vinegar and spices more intimately mixed, or in a larger proportion. Of the first we need not speak particularly, but only to suggest the necessity of gradually thawing meat preserved by ice, as its texture is otherwise destroyed. Salt condenses the muscular fibres, and renders them harder of digestion; but a large proportion of sugar lessens the inconvenience, and nitre is said to have a similar effect. Nitre, however, in the quantity employed, is by no means a powerful antiseptic; and, as a condiment, it seems of little importance. It chiefly imparts a more uniform and pleasing red colour than salt. The poignancy of the salt, however, ren-

ders many substances much more digestible, particularly the fatter part of the hog, the bacon. This, if cut thin, is easily, when broiled, borne by the tenderest stomach, and the addition of vinegar assists its digestion. Sugar, we have said, does not harden the animal fibres, and it preserves meat very successfully. It is usually mixed with salt, though in too small a proportion. The weight of each should be equal, or of the sugar superior; and the kind used should be the coarsest brown. Smoke is employed sometimes alone to preserve fish and animal food; sometimes, as in the herring, bacon, and some forms of Indian cookery, to give a peculiar flavour. If not carried so far as to dry and harden the meat, it seems to render it by no means unwholesome, or difficult of digestion. If the red herring is peculiarly indigestible, it is owing to the rancidity which its oil acquires in the preparation.

Vinegar is seldom employed to preserve animal food. Brawn owes little to it; for, composed of gelatinous matter not easily putrescible, it is preserved by preventing the access of air, in consequence of its being tightly rolled. To vinegar and salt we owe the preservation of many different kinds of fish; but for a long continuance of their perfect state, spices must be added. In the sauer kraut, the acetous acid, which contributes to the preservation of the cabbage, is formed by its spontaneous fermentation. Potted meats owe their preservation to spice, and to the air being excluded.

In all these instances, hard salted meat excepted, we do not find that the food is rendered less digestible. The warmth of the condiment may prevent this effect; but we must at the same time reflect, that these highly seasoned dishes are eaten only in small quantities.

The condiments added in the cookery, or at table, are, salt, vinegar, pickles, spices, wine, ardent spirit, soy, ketchup, mushrooms, oil, sugar, and various indigenous roots and vegetables, with a slight preparation, or in their natural state, as well as some animal substances, particularly fish. Of the ancient condiments we cannot speak with precision. The *asafoetida* supplied the flavour of garlic; the *garum* was not very distant from the anchovy; and many of their native vegetables are supplied at our tables, by the more pleasant aromatics of the east. What seems disgusting in ancient cookery, was perhaps not really so; as partly from custom, more certainly from the proportion employed, the effect might be pleasing. We know that even *asafoetida*, rubbed only on a warm plate, gives a more pleasing flavour than garlic; and that a judicious mixture of different spices is not only more agreeable, but often more wholesome than a large proportion of one only. Who would think of adding a red herring to soup? yet it is often done with success; and, in a small proportion, gives the flavour of ham. We should have apologised for entering so largely on the subject of cookery, but that a most respectable "brother of our order" has indulged his taste in publishing a collection of receipts, in a work entitled *Culina Famulatrix*. We shall, however, chiefly enlarge on condiments, as salutary or otherwise, and shall notice each in its order.

*Salt*, we have already remarked, is almost the universal condiment of animated nature; and it is by no means improbable that the extinction of the vast animal, the mammoth of America, was, in a great degree, occasioned by their collection in search of their prey

near the salt lakes of the Alleghany mountains, at the time of some general convulsion; such at least is probable from the vast collection of their bones in that spot. Salt, in this instance, acts as a stimulant; for its excess is as destructive as its moderate use is salutary. Even an oyster may be killed by an additional quantity of sea salt to sea water. As it is void of flavour, we seldom use it in excess; and we only see the effects of its increased quantity, in the constant use of salt provisions at sea. But to the effects of salt at sea must be added the unalimentary quality of animal food long kept in this state, as well as the almost constant moisture to which sailors are exposed. In some instances, when used too largely, it is said to have brought on symptoms of sea scurvy even on shore.

*Vinegar* we now speak of as a condiment, occasionally used. When in a perfect state, it is scarcely ever, in a moderate quantity, injurious. Even the most acid stomachs, and pregnant women most injured by acedents, may use it with safety. The fact is, that its ulterior change corrects acidity; and with animal food little injury will result. With vegetables *alone* it is not so innocent; yet in this way it is rarely taken but by the robust, to whom no diet is particularly inconvenient. Vinegar, as has been observed, renders some gross animal substances more digestible; but others it seems to harden, and to lessen their solubility. Yet we have seldom found it injurious but with shell fish; and oysters, cockles, muscles, crabs, and lobsters, are we think less easily digested when vinegar is added. The three first when pickled are certainly less soluble. The various flavours given to vinegar, which is by this means so infinitely diversified, must not be an object of our attention, for it is still vinegar unaltered in its essential qualities. We know a gentleman who never makes a salad without five kinds of this vegetable acid.

*Pickles* are little more than vinegar in a solid, and, we may add, in its most inconvenient and indigestible form. These are vegetable substances preserved by means of salt and vinegar; but the salt, in the early part of the process, chiefly hardens and contributes to their preservation. Should the curious reader wish to pursue the subject more closely than our limits will admit, we would refer him to the fourth volume of the *Amœnitates Academicæ*, in which he will find (p. 536) an entertaining and a not uninteresting essay "*De Acetariis*," by M. Van der Burg, in reality by Linnæus himself.

The simplest form of the acetaria is that of the salad, which takes its name from the ingredient, which should be in the least perceptible proportion, salt. The advantages and disadvantages of salads arise from the choice. The lettuce is soporific, the endive and celery acrimonious; but the power of the first is inconsiderable, of the latter lessened or destroyed by blanching (etiolation). The young mustard, the cresses, and the water cresses, are warmer; but these will be spoken of under another head. In general, salads to the young and strong are extremely wholesome, and excellent correctors of alkalescency. In the weaker stomachs, the addition of mustard renders them less inconvenient, though the coldness is often troublesome. Sliced cucumber can seldom be rendered digestible, even by the warmest spices, except in young and robust stomachs.

Vegetables which are preserved by vinegar are chiefly

those which are smooth, tasteless, and tolerably firm. Modern luxury flavours them highly with shalot, garlic, or the seeds of the nasturtium, and with advantage. The mango, the Indian plum, is highly flavoured with garlic; and we emulate it in a similar preparation of the unripe melon. The yellow and the warmer pickles of the East and West Indies we also imitate by the admixture of a variety of substances, preserved and flavoured in the same way, styled pickalilla. The warmth of the West India pickle we obtain by the addition of the capsicum, raised in our green houses.

The pickles of our own climate are chiefly the cabbage, red or white, rendered yellow by art; the young cucumbers (gerkins,) the larger cucumbers, or unripe melons (mangos,) the unripe walnuts, the naturally acid gooseberries, berberies, lemons, the samphire (*crithmum maritimum* Lin.), the buds of the cappariss, the tops of broccoli, sliced beet root, &c. In general, the firmer vegetables are the least wholesome; and those, without the additional warmth of other vegetable substances or spices, often produce inconvenience in weak stomachs. Perhaps, in general, they are injurious by exciting a false appetite, without carrying with them sufficient correction.

*Spices* are more harmless condiments; since, if they contribute to convey a larger proportion of nutriment, they warm the stomach, and enable it to perform its office more perfectly. It must be indeed admitted, that the organ will be ultimately weakened by over distention; but if not greatly abused, the use of spices does no real nor permanent injury. The safest of the spices is, apparently, the common pepper. It is at the same time the most durable and inflammatory; but the quantity employed renders the last quality of little effect. The Cayenne pepper is more pungent, but more transitory in its stimulus; and we have had great reason to think that much of its warmth is lost on the throat and fauces. Ginger is peculiarly warm, and its warmth is permanently exerted in the stomach, which renders it an excellent addition to cold and flatulent drinks. The warmth of cloves is more inflammatory, and in a small proportion not unpleasant. Mace is milder; but, from its strong flavour, is used in too small a quantity to be either useful or injurious. The capsicum and chili, though scarcely meriting the name of spice, as void of aroma, are, in qualities and botanical analogy, nearly related to Cayenne. The pimento, uniting the flavour of different spices, seems also to unite their qualities; and the cinnamon, chiefly employed for its flavour, unless used medicinally, has little pretensions to either praise or blame.

*Wine* must be reckoned among the condiments; for though its addition to sauces is in too small a proportion to produce any considerable effect; yet it is often drunk at table, and adds to the inclination for an additional quantity of food, and the power of the stomach to digest it. This advantage, if it may be styled one, is chiefly obtained by the drier and stronger wines, as Madeira, sherry, and white port; more effectually by the strong and sharp wines, as rhenish, vin de grave, and old hock. The sweeter wines pall the appetite, and are reserved for the dessert, whose sweetness would destroy the flavour of the others. We then find the Malmsey, Madeira, the Frontinac, Tokay, and Cape wines, introduced. This finishes the studied luxury of a modern

dinner, where every thing is nicely calculated to add to the quantity, since the second is more poignant than the first course, and the dessert more attractive than the second: the wine joins in the conspiracy against the powers of the stomach, which is thus daily undermined, and its tone gradually destroyed. Wine is perhaps sometimes really useful in this view; we mean, in some instances where the stomach requires the assistance of a stimulus to take even the necessary quantity; and in such cases it may be even taken with advantage before dinner. In this situation hock is preferable: the next is Madeira; sherry, white and red port, follow in succession. When the whole body is exhausted also by fatigue, the stomach will often refuse the necessary food, until it is a little revived by a glass of wine.

*Spirits*, either alone or with water, are occasionally taken with similar design; but these are in every form, except occasionally as medicines, injurious. Brandy is chiefly preferred; but it is scarcely less hurtful than either of the others.

*Soy* is imported from the east. It is the production of the bean, the *dolictos soia* Linnæi Sp. Pl. 1023, which is chiefly prepared by a spontaneous fermentation, with the addition of salt, and a small proportion of flour. It merely gives a flavour to sauce.

*Ketchup* is prepared from mushrooms or walnuts, with the addition of salt, and generally some spice. These two fluids are infinitely diversified with the flavour of shalot, the warmth and pungency of Cayenne vinegar, the taste of anchovies, &c.; and sold in many forms, with a great variety of names, according to the fancy of Mr. Burges and others. They are not injurious if they do not tempt the appetite too far, and increase the load beyond the powers of the stomach to digest. *Mushrooms* we have added to the list, which, though in a slight degree nourishing, are chiefly taken for their flavour. See AMANITA.

*Oil* must be reckoned among the condiments occasionally used, though void of flavour. Its chief use is as a sauce with vinegar, to pickled fish, or in salads. It is said in the former to correct the alkalescency of the fish, and assist its solubility. But if this advantage be denied, it may be at least pronounced innocent. It is not easy to conjecture the origin of its use in salads. We have suspected that it may have arisen from a suspicion of some poisonous herbs being incautiously mixed with the others. Its more obvious advantage is, that it gives a richness to the salad, and by the assistance of the egg employed to mix it with the vinegar, conveys the poignancy of the latter more uniformly to every part of the vegetable, in consequence of its viscosity. Whatever may have been the cause or effect, it is very generally employed; and if not advantageous, is pleasant and innocent.

*Sugar* is not commonly used as a condiment except in the form of currant jelly, or occasionally with mint sauce in the early season of lamb. In every instance it is at least innocent.

*Various indigenous vegetables* furnish also a variety of condiments. We employ the root of the horse radish, the capsules and seeds of the nasturtium, the seeds of the mustard, the cresses, the water cresses, and the young mustard, in their earliest periods, sometimes when even the seed leaves only are expanded. These plants belong to the order *siliculosæ*, all of which are in the

same groupe, the *tetradynamia* of Linnæus, one of the most natural classes of the sexual system. They are, without any exception, pleasant and salutary. Indeed they have been commended more highly than they merit, from circumstances that may for a moment be allowed to detain us. When stall feeding was not common, families in general preserved their winter's stock of food by means of salt; and symptoms of scurvy and of biliary calculi were often the consequence, after some months confinement to this diet. The early vegetables were then sought with alacrity, and their powers were consequently more conspicuous. These vegetables still retain their character, though the occasion of their use is removed. The flour of the mustard seed seems not to have been employed very early, but it is now a general favourite; and in France it is prepared with peculiar care, and enriched with a variety of additional flavours. Were we to write another *culina famulatrix*, we might enlarge copiously on this subject, and some similar ones, from a pleasant work published annually in France, of which the third year has just appeared, viz. *Almanach des Gourmands*, the *Almanack of Epicures*. In this the variety of mustards and other sauces are described; "which have the inestimable advantages of enabling you to eat much, and for a long time without inconvenience." It is sufficient, however, in our situation to remark, that all these indigenous condiments are wholesome.

Another kind, the last of which we shall speak, is that prepared from fish. Caviare prepared from the roe of the sturgeon is sometimes employed in this way, though more usually eaten alone. Anchovies, which dissolve by heat, are employed as a sauce for fish; but what is styled their "essence," is little more than the sordes that remain. When the fish itself is employed, and the solution clarified, it is almost equally clear with water; and the flavour of the anchovy is delicate and pure. Crabs, lobsters, oysters, cockles, and prawns, are all in turn employed as sauce for fish, and occasionally the oysters for some kinds of fowl; but when dressed, they are far from being easy of digestion.

It may be supposed that we have been too lenient to these condiments, which have excited the indignation of the moralist, and of the diætic physician. Could we return to a state of nature, or indeed were such a return desirable, we might have employed a different language; but while they assail us in numerous shapes, it was of more importance to appreciate with some accuracy their various merits than to reject them with indignation.

The experimental physician, who endeavoured to imitate the process of digestion in his phials, was surprised to find that all the condiments, which he employed, retarded the spontaneous changes; and all were at once condemned. Independent, however, of the common argument, that digestion is a process connected with a being possessed of life, we might ask what reason induced him to confound a rapid with an easy digestion. Various inconveniences we know attend a quick digestion; among which we may reckon flatulence, headach, and a symptom not generally attributed to this cause, a faintness within about an hour or two after eating. We recollect that Psalmanazar, who in support of his fiction was obliged to eat his meat raw, found great inconveniences from too quick digestion, which he removed by mixing large

quantities of pepper with it. In fact, then, condiments may be serviceable by retarding this process; and we have employed them medicinally for this purpose. Their use has been thought disgraceful, as implying a deficiency of appetite and impaired health, but without reason. The person who employs them may indeed often eat without their assistance, but he can dine more agreeably with it; and while "to enjoy is to obey," we find little objection to condiments but in their abuse.

**CO'NDIO**, to EMBALM; also *conditura*, and *pollincio*. Embalming is as ancient as the first record of the character of physician. See Genesis, ch. i. v. 2. It is still practised, but not generally. On this subject see Paré Dionis's Surgical Operations; Gooch's Treatise on Wounds, p. 456; Greenhill's Art of Embalming; Bell's Surgery, p. 465.

**CO'NDITUM**, (from *condio*, to preserve). PRESERVES. They are made by steeping, or by boiling recent fruits in syrup or a solution of sugar. It is afterwards either kept moist in the syrup, or taken out and dried, that the sugar may candy upon it: this last is the most usual method. The art was formerly a branch of the apothecary's business, but now is wholly in the hands of confectioners.

The Latins and the latter Greeks meant by *conditum* a sort of *acratomeli*; that is, a wine impregnated with honey and aromatics. See **MULSUM**.

**CONDITU'RA**. See **CONDIMENTUM** and **CONDIO**.

**CONDU'CTIO**, (from *conduco*, to draw along,) in Cælius Aurelianus it means a spasm or convulsion.

**CONDU'CTOR**, (from *conduco*, to guide). A CONDUCTOR is an instrument used in surgery for the direction of a knife when a sinus is laid open. It is also a name of the instrument called a **GORGET**, which is used as a conductor in the operation of lithotomy.

**CONDUPLICA'TUM FO'LIIUM**, (from *con* and *duplicor*, to be doubled). A term in foliation, signifying that the sides of the leaf, while in the bud, are doubled over each other at the midrib. It is used also in the sleep of plants in the same sense, when the leaves during the night fold together in the same manner.

**CONDYLOI'DÆ**, (from *κονδυλος*, a joint, and *ειδος*, form, likeness). **APOPHYSES**. See **MAXILLA INFERIOR**.

**CONDYLO'MA**, (from *κονδυλος*, a joint or tubercle). A TUMOUR; so called from its resemblance to a *condyle*, a joint bent, or a tubercle. It is a hard eminence, which arises in the folds of the anus, or a hardening or a swelling of the rugæ. These tumours also sometimes happen in the orifice of the uterus, and other parts. It is variously described by authors; by some as a tumour of the cuticle; by others as an instance of sarcoma. An anonymous French writer says, it is in general a fleshy excrescence which appears on the fingers, hands, feet, and principally about the anus, the perinæum, and the private parts of both sexes. He adds, that warts, the tumours called *ficus*, *marisca*, *sycosis*, and *thymus*, are different instances of *condyloma*. See **ATRICES**.

Authors abound with unnecessary distinctions respecting these tumours; but all tubercles and fungi, whether within the verge of the anus or more outward, are of the same nature, and are cured by the same method,

whether called *condyloma*, *ficus*, *fungus*, or *crista*, and are tumours of the glandules of the part; which, increasing by degrees, prove painful and troublesome. Those who are troubled with the piles frequently suffer from them; and they often appear in the pudenda from the lues venerea.

If the roots are small, a ligature may extirpate them; if broad, they are best removed by a caustic, but care must be taken that it doth not injure any other part.

See P. Ægineta, Celsus, Heister, Turner, Wiseman; Bell's Surgery, vol. ii. p. 264.

**CONDYLO'MA**. A CORN. See **CLAVUS**.

**CO'NDYLUS**, (from *κονδυ*, an ancient cup shaped like a joint). A **CONDYLE**. It is a protuberance in any of the joints, formed by the epiphysis of a bone. In the fingers it is called the knuckles. See **PROCESSUS**. In botany it signifies the joints of plants.

**CONEI'ON**. In Hippocrates it is an appellation of the *cicuta*; from *κονος*, turbo, a turning or whirling round; because it produces a vertigo in those who take it internally.

**CONE'SSI**. (Indian). Called also the *codagapala*, *conessi seca*, *cadagushali*. It is the bark of a small tree, called *arbor Malabarica lactescens*; *jasmini flore odoro*, *siliquis oblongis*, growing in Ceylon and Malabar, and on the Coromandel coast, where it is called *conessi*. It is blackish outwardly, and covered more or less with a whitish moss or scurf, which should be scraped off. To the taste it is gratefully austere and bitter. It is commended in diarrhœas, and half a drachm may be taken three times a day; or in sour milk it restrains not only alvine fluxes but hæmorrhages. The root, boiled in water, makes a useful fomentation against inflammatory tumours; and, taken inwardly, destroys worms. When used, it should be fresh powdered, for it soon loses its medical qualities under any form or preparation. When taken to restrain a diarrhœa, an emetic of ipecacuanha should precede its use. Those with whom a diarrhœa is frequent, in moist weather, are much benefited by its use, if a dose is taken morning and evening. Its genus is unknown. Raii Hist.

**CONFECTA**, (from *conficio*, to make up). **CONFITS** or **SUGAR PLUMS**. Seeds or other substances incrustated with sugar. These, when impregnated with purging ingredients, are given to children who will not take the usual forms of medicines.

**CONFECTIO**, (from the same). A **CONFECTION**; called also *aligulus*. In general it is any thing prepared with sugar, and the same with *conditum*. The latter is usually dry; the confectio a soft electuary. The dry confects are now a branch of the confectioner's business, and are the roots of eringo, the peels of oranges, &c. which are incrustated with sugar, and are called **CANDIED ROOT**, or **PEEL**. The London college prescribes the following soft electuary: the **CORDIAL CONFECTION**, now called the **AROMATIC CONFECTION**.

Take of zedoary in coarse powder, saffron, of each half a pound; distilled water, three pints; let them macerate for twenty-four hours, then press and strain them. Evaporate the strained liquor to a pint and a half, to which add the subsequent ingredients reduced to very fine powder; compound powder of crab's claws, sixteen ounces; cinnamon, nutmegs, of each two ounces;

cloves, one ounce; lesser cardamom seeds husked, half an ounce; double refined sugar, two pounds; and thus form the confection. Pharm. Lond. 1788. This is altered from the last Dispensatory, and may be considered as an improvement. It is certainly an agreeable cordial and carminative, but should not be long kept, as it loses its efficacy. It is substituted for the confect or cordial of Sir Walter Raleigh.

CONFECTIO ALKE'RMES. See CHERMES.

CONFECTIO ANACA'RDII. See ANACARDIUM.

CONFECTIO AROMA'TICA. See CONFECTIO CARDIACA.

*Confectio Damocratis*. DAMOCRATES'S CONFECTION.—This was formerly called *mithridatium*, from Mithridates, king of Pontus and Bithynia, who, after the example of Attalus of Pergamus, is said first to have experienced the virtues of simples separately, and then to have combined them. But it should be noted that the original compound, as prepared by Mithridates, consisted of but a few ingredients. Serenus Sammonicus says, that when Pompey took the baggage of this prince, he was surprised to find that this antidote consisted of only twenty leaves of rue, two walnuts, two figs, and a little salt. Of this he took a dose every morning, to guard himself from the effects of poisons. It is, however, probable this was designed to deceive, as the preparation used by the king of Pontus has been handed down with great care, and is a combination of aromatics and nervous medicines with opium. If, as Dr. Fordyce alleges, a variety of aromatics is more useful than a large dose of a single one, we cannot see with what propriety the mithridate is rejected, except on the common principle, "Est modus in rebus et certi denique fines." At all events, the mithridate—for we well remember its use, and its being faithfully, at least with tolerable fidelity, prepared—was a warm useful opiate. It is now, however, thrown out of the London Dispensatory of 1778.

CONFECTIO OPIA'TA. See PHILONIUM.

CONFECTIO SAPIE'NTUM. See ANACARDIUM.

CONFERTUS, (from *confero*, to bring together). In botany it means very numerous, and crowded together. See ATHROOS.

CONFIRMA'NTIA MEDICAME'NTA, (from *confirmo*, to strengthen). Medicines which restore or confirm the strength of the body, or any part of it: or medicines which fasten the teeth in their sockets. See TONICA.

CONFLUE'NTIA, (from *confluo*, to flow together). A term used by Paracelsus to express the agreement, conjunction, or confederation of the microcosm with the stars, or of a disease with remedies: in botany it means growing together in partial masses, so as to leave the intermediate parts quite bare; and in small pox, the running together of the pustules when crowded.

CONFEDERA'TIO is of the same import. From *confedero*, to agree together.

CONFORMA'TIO, (from *conformo*, to shape, or fashion). CONFORMATION. Some diseases are called *morbi malæ conformationis*, or organical diseases; that is, which depend upon the original ill conformation of the parts, or on the change of their structure from disease. These, if external, may admit of a surgical cure; and proper exercise, regimen, and medicines,

may sometimes contribute much to the relief even of those which are internal. See also DIAPLASIS.

CONFORTA'NTIA, (from *conforto*, to strengthen). See CARDIACA.

CONFRICA'TIO, (from *con* and *frico*, to rub together). In pharmacy it is the reducing of any easily friable substance to powder by rubbing it with the hands; or the rubbing any soft and succulent vegetable with the hands to express the juice.

CONFRICATRI'CES, (from the same). Lascivious women, who induce a variety of chronic diseases from unnatural practices.

CONFUSÆ FE'BRES, (from *confundo*, to confuse). Bellini thinks that he has met with two fevers attending at the same time, beginning and ending together, but so confusedly as not to be distinguished. Bellini, however, in his distinctions, is too refined, and often himself confused.

CONFUSA'NEUS PA'NIS, (from *confundo*, to mingle together). Bread made of meal, from which the bran has not been separated.

CONFUSIO, (from the same). A disorder of the eyes, which happens when, upon a rupture of the internal membranes which include the humours, they are all confounded together. It is also a mental disease when the ideas are not clear and discriminated. Some authors have laboured under it during their whole lives.

CONGELA'TI, or CONGELA'TICI. Persons afflicted with a catalepsy. See CATALEPSIS and CONGELATUS.

CONGELA'TIO, (from *congelare*, to freeze). CONGELATION, and COAGULATION. It is such a change produced by cold in a fluid body, that it becomes apparently, sometimes really solid. Water is rarified or expanded by congelation; but this depends on the sudden separation of the air. Iron, plaster of Paris, and many other substances, expand at the moment of congelation. Animal fats, and some oils, usually contract.

The calcareous stalactites produced in caverns from the drops of petrifying waters are called congelations.

CONGELATI'VA MEDICAME'NTA, (from *congelare*, to congeal). Medicines which inspissate and dry; or are employed to check discharges.

CONGELA'TUS, and COGELA'TIO, (from *congelare*, to freeze). FROZEN or FROST BITTEN. Persons thus affected by the cold are compared to cataleptic patients, but still there is much difference between the diseases.

When a man is benumbed with cold, and he attempts to warm himself at the fire, the parts exposed to the heat are painful, and a mortification is the general consequence. Thus frozen fruit, if put into water nearly freezing, recovers; but in warm water, or in a warm place, soon rots. Those who are severely affected with cold, should first put the frozen part into cold water, or cover it with snow; and next into water somewhat above the freezing point, until a sense of warmth is perceived, or some degree of motion returns. At this time a little warm wine, mixed with camomile tea, may be drunk, and the warmth gradually increased. A mortification will be in this way avoided.

When travellers begin to be drowsy in the cold, they should redouble their speed to extricate themselves from

danger; for though their sleepiness is urgent, it is always fatal.

The heat of our bodies, when in health, very commonly exceeds that of the ambient air: a considerable degree of cold is consequently required to freeze our fluids, and the extremities are the first affected, as most distant from the centre. When a mortification from cold approaches, the part affected by it is first pale, then red: this redness is attended with a troublesome pain and a violent itching; after which the colour becomes almost purple, and at last black.

In these cases, the parts, by their sedative powers of the cold, are deprived of life; or at least their irritability is suspended, and consequently accumulated. Should heat be applied, the excessive action, which is the consequence, soon induces mortification, that would otherwise be avoided. By introducing the heat gradually, the accumulated irritability is sufficient to restore the life of the part. When gangrene has actually taken place, the increased action of the vessels, as usual in such instances, is excited to separate the morbid from the sound part. There is not the slightest evidence, that the organic structure is destroyed by the expansion of the fluids during congelation.

See Tissot's Advice to the People; Van Swieten's Com. on Boerh. Aph. 422, 427, 454; Med. Mus. vol. i. p. 71.

CONGE'NERES, (from *con* and *genus*, of the same kind). When spoken of muscles, it imports those which concur in the same action.

CO'NGER, or CO'NGRUS, *κογχρος*, (from *γρᾶω*, to devour; so called from its voracity). The CONGER EEL. It is a large sea eel, often called the serpent. The flesh, when deprived of its rancid flavour by soaking in salt and water, resembles bad veal.

CONGE'STIO. CONGESTION, or COLLECTION. (From *congero*, to gather into a heap). A swelling which gradually arises, and slowly ripens; in opposition to that defluxion which is quickly formed and terminated.

CO'NGIUS. A GALLON. This is a very ancient measure, and is generally said to have been equal to ten pints of wine, and nine of oil. The Athenian congius, or conchus, weighed nine pounds, and the Roman weighed ten, or contained ten Roman pints of wine. In the London and Edinburgh Dispensatories the gallon is only eight pints. See CHU.

CONGLOBATA GLANDU'LA. A CONGLOBATE GLAND, (from *conglobo*, to gather into a ball). All the glands are either conglobate or conglomerate. A conglobate gland is a little smooth body, covered with a fine skin, by which it is separated from every other organ, only admitting an artery and a lymphatic, and affording a passage to a vein, or another to the same lymphatic. See Winslow's and Keil's Anatomy.

CONGLOMERA'TA GLANDU'LA, (from *conglomerato*, to heap up together). A CONGLOMERATE GLAND is composed of many little glandular bodies, united in one common membrane. All their excretory ducts sometimes unite, through which the secreted fluid passes. Sometimes the ducts uniting form several ducts, which communicate with one another by anastomosing canals, as in the mammæ. Others again have several ducts without any communication with each other; as the glandulæ lacrymales et prostatae; and occasionally each gland hath its own excretory duct, through which

it transmits its fluid to a common reservoir, as the kidneys. See Winslow's and Keil's Anatomy. See GLAND and SECRETION.

CONGLUTINA'NTIA, (from *conglutino*, to glue together). Healing medicines.

CO'NIA. LIME, (from *κοινῶς*, to whiten). When joined with *στακτη*, it means lixivium, or ley of vegetable ashes; or wine impregnated with cones of fir; from *κωνος*, a cone. Dioscorid. lib. v. c. xlvi.

CONIFERÆ A'RBORES, (from *conus*, a cone, and *fero*, to bear). Trees which bear cones, as the cedar, fir, and pine.

CONI'LE. See MYRRHIS.

CO'NIS, (from *κωνίς*, dust,) fine powder; ashes; a nit in the hair; scurf from the head; and sometimes lime.

CONISTE'RIMUM, (from the same). See APODYTERIUM.

CONJUGA'TA, (from *con* and *jugo*, to yoke together). In botany it means growing in pairs.

CO'NIUM MACULA'TUM and MA'JUS. See CICUTA MAJOR FETIDA.

CONJU'NCTA CAU'SA, (from *conjungo*, to join together). The IMMEDIATE CAUSE. See CAUSA.

CONJU'NCTA SI'GNA. The pathognomonic signs of a disease.

CONJUNCTI'VA TU'NICA, (from the same). The conjunctiva is erroneously confounded with the adnata; they are two distinct coats, and both but partial coverings of the fore part of the eye, though the conjunctiva is reflected, and also spread over the inside of the eye lids. This is a thin transparent membrane, which lines the inner surface of the eye lids, and at the edge of the orbit has a fold, that is continued forward over the anterior half of the globe of the eye. It is exterior to all the other coats of the eye, and connected with the albuginea, by means of a cellular substance, from which it may easily be separated in the dead subject by dissection. The conjunctiva of the eye lids is perforated by many minute foramina, which suffer a thin serum to exhale, to keep a moisture over the globe of the eye. This membrane is transparent, and, covering the albuginea, gives the whiteness to the portion of the eye usually distinguished by this appellation. See Ware's Remarks on the Ophthalmia, &c. p. 5. It is sometimes called the *mucous coat*.

CO'NNA. See CASSIA FISTULARIS.

CONNA'TUS, (from *con* and *nascor*, to grow together). In botany it means two or more distinct things growing together, and having the appearance but of one; as two apples, two nuts, or two leaves.

CONNE'CTIO, (from *con* and *necto*, to knit together). See SYMPHYSIS.

CONNE'XUS, (from the same). In botany it means growing in pairs.

CONOI'DES, (from *κωνος*, a cone, and *ειδος*, likeness). Any body in the shape of a cone. See PINEALIS GLANDULA.

CONQUASSA'TIO, (from *con* and *quatio*, to shake together). CONQUASSATION. In pharmacy it is a species of comminution, or an operation by which moist concreted substances, as recent vegetables, fruits, or the softer parts of animals, are agitated and bruised till they are reduced to a soft pulp.

CONSE'RVA, (from *conservo*, to keep). A con-

SERVE. Conserves consist of recent vegetable matters and sugar, beat together into one uniform mass.

On account of the large quantity of sugar contained in conserves, it is obvious that they are chiefly useful as an auxiliary to other more efficacious drugs. Though of the conserves of lavender, wood sorrel, mint, rosemary, orange and lemon peels, arum, or wormwood, a useful dose may be taken, if the proportion of sugar is diminished.

Mucilaginous substances, if mixed with sugar, become glutinous, and astringents soft. The more intense bitters are improper for this form; and lightly flavoured vegetables soon spoil: the latter must, therefore, be prepared extemporaneously.

The general observations for properly making conserves are but few: leaves are to be picked from their stalks, and flowers from their cups. When the flowers or leaves are properly prepared, they must be beat into an uniform mass, in a marble mortar, with three times their weight of powdered lump sugar; but we are often obliged to diminish the proportion to twice, or sometimes to an equal weight. Orange peel may be rasped, or ground in a mill, and then beat up with the sugar. Roses are to be ground before they are beat into a conserve. If they are infused in a large proportion of water, and this is separated by expression, their bitterness, perhaps their virtue, is extracted.

CONSERVA'TIO, (from *conservo*, to keep). In pharmacy, the same as *asservatio*; pickling, or preserving from putrefaction and evaporation, by some additions; or exclusion of air, heat, or moisture.

CONSERVATI'VA MEDICI'NA, (from the same). That part of medicine which relates to the preservation of health. But for this purpose medicine is of little use.

CONSILI'GO, (from *con*, and *siligo*, a kind of fine corn; so called from its being usually found among corn). See *HELLEBORUS NIGER HORTENSIS FLORE VIRIDI*.

CONSISTE'NTIA, (from *consisto*, to abide). The state or acme of a disease. When applied to the fluids, excrements, or excretions, it imports their consistence.

CONSOI'DES. See *AMIANTHUS*.

CONSO'LIDA, (from its supposed power of consolidating and agglutinating things broken). *COMFREY*; called also *alum*, and *alus Gallica*.

CONSO'LIDA MA'JOR; *symphytum majus*; GREATER COMFREY. *Symphytum officinale* Lin. Sp. Pl. 195.

A rough hairy plant, with large, somewhat oval, pointed leaves, producing, on the tops of the branches, spikes of white or purplish pendulous, nearly cylindrical, flowers, followed each by four shining black seeds. The root is thick and fleshy, black on the outside, and white within. It is perennial, grows wild in moist grounds, and flowers in May or June. There is a sort with purple flowers, but it is rarely to be met with. The purple and the white flowers are but varieties of the same species.

The whole plant is used, but the root is the only part that deserves notice; it yields in boiling about two thirds of its weight of mucilage, almost void of smell and taste, and similar to that from the *althæa*, but more tenacious. The comfrey is, therefore, probably preferable. This mucilage is its only medicinal principle. See *Lewis's Mat. Med.* *Neumann's Chem. Works.* *Raii Hist.*

CONSO'LIDA AU'REA, and AU'REA CO'RDII. See *CHAMÆCISTUS*.

CONSO'LIDA ME'DIA, and MINIMA. *DAISY*. See *BUGULA*, *BELLIS MAJOR* and *MINOR*.

CONSO'LIDA MI'NOR, and RUBRA. See *PRUNELLA* and *TORMENTILLA*.

CONSO'LIDA SARACE'NICA. See *VIRGA AUREA*.

CONSO'LIDANS. CONSOLIDATING, (from *consolido*, to make firm). This is applied to medicines that produce new flesh.

CONSO'MME, CONSUMMA'TUM, (from *consummo*, to make perfect). It is a broth so strong as to concrete into a jelly when cold. Frequent mention is made of it in the French medicinal writers.

CONSPE'RSIO, (from *conspergo*, to sprinkle). See *CATAPASMA*.

CONSPICI'LUM, (from *conspicio*, to behold). SPECTACLES.

Spectacles are either convex, concave, or plain. The first are adapted to old persons; the next to those who see only with distinctness at a small distance; and the third, formed of glass with a light green or blue shade, are designed to defend weak eyes from too strong light. The form of the eye in old and near sighted people has been explained under the terms *AMBYOPIA*; and the subject will again recur, vide *PRESBYTÆ* and *MYOPES*.

Those who wear spectacles should be very cautious to have the glasses ground with the most perfect accuracy, and should apply to opticians of credit, rather than to itinerant Jews; for the aberrations of the rays produced, by an imperfect figure of the glass, strain the eye to distinguish the image; from this cause indistinct. For a similar reason, the glasses of old people should be not at all, or very slightly, tinged: and the glare which arises from a candle, or a strong sun, may be better avoided by a shade against the former, or over the eyes, to guard against the latter.

It has been doubted whether spectacles should be used to preserve the sight. We think that in old persons they will be useful: with the near sighted, who are usually young, they should be discouraged. Old people will save their eyes, and there is little danger of exhausting the degrees of convexity: indeed none. The young will not, indeed, exhaust the degrees of concavity; but the other senses should be kept "on the alert," while they can supply the place of distinct vision. The hearing, the feeling, even the facility of conjecture, are kept alive by disusing spectacles; and we should improve all our powers. As we have already hinted, the near sighted person should use the number next below that of distinct vision, and he will soon attain it. Habit, in this way, will coincide with the change which age induces; and not to see with the utmost acuteness, is still an advantage to those who could otherwise see very imperfectly.—All this is, however, refinement; for spectacles used with little caution or discrimination have seldom done harm, if the glasses are good.

Pebbles, which admit not of scratches, should be in every instance preferred.

CON'STANS, (from *consto*, to stand firm). When applied to the strength, or vital powers, it imports firmness, or a good condition.

CONSTELLA'TUM UNGUE'NTUM. It is an

ointment made of earth worms, cleansed, dried, powdered, and mixed with the fat of boars or bears.

**CONSTIPATIO**, (from *constipō, to crowd together*). *Obstipatio, adstrictio*. **COSTIVENESS**. Dr. Cullen gives this disorder the name of *obstipatio*. A person is said to be costive, not only when the contents of the intestines are not daily discharged, but also when what is discharged is too hard to receive its form from the impress of the rectum upon it. The daily discharge is, however, relative; for the constitution, accustomed only to this relief every four days, can scarcely be said to labour under disease, if a week should elapse between the periods. See **OBSTIPATIO**.

Hoffman observes, that costiveness is generally owing to spasms in the intestines themselves, or is propagated by consent; but various causes conduce to this habit, particularly a want of irritability of the intestines and a sedentary life.

This habit of body is generally attended with headach, vertigo, disagreeable taste in the mouth, and want of appetite: it is a frequent cause of chronic complaints, which will be easily understood by what we have remarked respecting **CATHARTICS**; q. v.

The costiveness peculiar to studious people is much relieved by magnesia, with rhubarb, or the ol. ricini. Artificers who sit much, and work with their bodies leaning forward, are best relieved by the same medicines. In cases of melancholy, neutral salts, if long continued, are most effectual; for they leave no tendency to costiveness.

Women, during pregnancy, are sometimes costive; from the pressure of the child's head against the rectum. Care should be taken to prevent an accumulation of feces by an early administration of mild purges, for harsher ones are dangerous. Old people, from the weakness of their muscles, have hard feces collected in the rectum: and though laxative medicines procure a discharge of the thinner fluids, the indurated matter still lodges, except manual assistance is given. The late Dr. Warren employed, from an obvious connection, a *marrow spoon*.

Aloes, given in small doses, prove sufficiently laxative: and this effect is continued longer after its use, than is observed with respect to many other medicines. When flatulencies are very troublesome, if a little asafoetida is joined with it, more considerable relief may be expected. Calomel also often prevents other purging medicines from leaving costiveness behind. The extractum colocynthidis compos. united with calomel, and corrected by the addition of oleum carui, seu anisi, forms an excellent remedy for relieving and preventing costiveness, if used occasionally. The utility of Dr. James's analeptic pills have led to a suspicion of the utility of the antimonial, joined to the more active forms of resinous purgatives; and we have already mentioned the advantages derived from adding a grain of emetic tartar to a drachm of the colocynth pills for this purpose. A form we have often employed with success, consists of half a drachm of the gum pill, as much pill Ruffi, with ten grains of antimonial powder. Two or three of these pills approach very nearly in their effects to the analeptic pills of Dr. James. Habitual costiveness hath been much lessened both by the cold and hot baths, by early rising, and walking in the open air.

In the Lond. Med. Obs. and Inq. vol. iv. are two cases of costiveness which resemble diarrhœas.

VOL. I

**CONSTRICTIVA**, (from *constringo, to bind together*). See **STYPTICA**.

**CONSTRICTOR ALÆ NASI**, (from the same: for all muscles, called *constrictores*, have the power of straitening). *Triangularis; depressor labii superioris*. Fallopius first described these, though Placentinus claims the discovery. They rise fleshy below the root of the nares, immediately above the gums of the dentes incisores, and, ascending transversely, are inserted into the coats of the alæ nasi, and the superior part of the upper lip.

**CONSTRICTOR ANI**. See **SPHINCTER ANI**.

**CONSTRICTOR ISTHMI FAUCIUM**. From the uvula two arches run down on each side, and there is a cavity between them, where the tonsils are lodged. The anterior arch goes to the basis of the tongue, and is thus called; the other passes down the palatum molle, and goes to the pharynx, whence it is distinguished by the name of *fiolato-pharyngæus*.

**CONSTRICTOR LABIORUM**. See **SPHINCTER LABIORUM**.

**CONSTRICTOR MUSCULUS**. See **BUCCINATOR**.

**CONSTRICTOR PALPEBRARUM**. See **ORBICULARIS PALPEBRARUM**.

**CONSTRICTOR PHARYNGIS INFERIOR**. See **CRICOPHARYNGÆI**.

**CONSTRICTOR PHARYNGIS MEDIUS**. See **HYOPHARYNGÆUS**.

**CONSTRICTOR PHARYNGIS SUPERIOR**. See **CEPHALOPHARYNGÆUS**.

**CONSTRICTOR VESICÆ URINARIÆ**. See **DETRUSOR URINÆ**.

**CONSTRICTORES PHARYNGÆI**. See **PIARYNX**.

**CONSTRICTORII**, (from the same). Diseases attended with constriction.

**CONSTRINGENTIA**, (from the same). See **ASTRINGENTIA**.

**CONSUETUDO**, (from *consuesco, to be accustomed to*). **CUSTOM**. Custom and habit are two terms often used synonymously, and indeed the former is often confounded with the latter. By custom is meant a frequent repetition of the same act; by habit, the effect that custom has on the mind or body; so that the former is the cause of the latter.

It has been often alleged, and with truth, that we are creatures of habit. Custom produces a regularity in all our returning wants; and the hour of dinner, of exercise, or sleep, brings on the feeling of want, independent of any real demand. In general, the frequent and regular repetition of small impressions produces habit, and their influence is soon unperceived: violent impressions never become habitual; for, when repeated, the body or mind would sink under their force. The influence of custom on our sensations is singular. Accustomed sensations, as we have just remarked, are soon unnoticed; and it requires a little increased action to render them the objects of our attention. Yet, when the energy of the mind is excited by the sensation, custom adds to the power of discrimination. The shepherd will distinguish every individual sheep of a large flock; the painter discover beauties and faults invisible to the common eye; and the musician feel with pain the minutest deviation from tune. Custom, therefore, which blunts bodily sensations, renders the mental

ones more acute. Volition is not an exertion of mind, but apparently a simple impulse, directed almost necessarily to an end; and it is affected by custom, nearly like the organs of the body. Thus a sensation, which excited a perceptible exertion of volition, will, in time, produce it and the correspondent action, without our being sensible of its interference; and so rapid is this progress, that we seem to will two ends or objects at the same time, though they are evidently, when examined, distinct operations. But though by custom we are no longer sensible of bodily impressions, or the exercise of volition, yet the corporeal organs in their several functions acquire, like those of the mind, peculiar accuracy of discrimination. The musician is not, for instance, sensible of his willing any one motion; yet, with the most exquisite nicety he touches a particular part of the string, and executes a variety of the nicest and most complicated motions with the most delicate precision. Indeed, it appears to be a general rule in the animal economy, that if an idea has frequently produced a motion, its power is increased; but if the motion connected with the idea has been prevented, the power is diminished or lost.

It has been supposed that the will, by custom and exercise, may acquire a power over motions in the body not originally subject to it; and we think we have observed some instances of this power in a slight degree on the motions of the alimentary canal. The most striking instance of this kind, however, was the power which colonel Townsend obtained over the heart and arteries; and we know an eminent professor who, in his youth, could, and is perhaps still able to, produce a considerable effect on his pulse. But this effect of custom is very limited. Its power of increasing the force and facility of action of the moving fibres is sufficiently well known. In the action of medicines on the moving fibres we find some variety. Moderate power, by custom, loses its peculiar effect. Thus, the dose of emetics and laxatives, when repeated, must be increased; and the dram drinker gradually requires additional quantities, or augmented strength, of his liquor: but if the power be very active, the repetition gives greater facility of motion, as, by the repetition, the mobility of the moving fibres is increased. Another effect of custom on the moving fibres resembles the association of ideas. If two muscles, or the different parts of one muscle, have been used to act together, exciting the action of one will produce that of the other. If, however, this kind of association is prevented by a strong effort of volition, and strengthened by a different habit, they are induced to act separately, with the greatest precision. This power is constantly attained by musicians.

A singular effect has been attributed to custom, which may perhaps be more satisfactorily explained on other principles. As we usually feel only in the sentient extremities of the nerves, it has been supposed, that from custom we refer every affection of the nerve, in its course, to the extremities; and thus the sailor, who had lost his leg many years before, feels a pain in the toe. This, however, certainly does not depend on custom; for a disease of the origin, or in the course of a nerve, is at once referred to its extremity, though the sensation was never before experienced.

Custom, we find, regulates the degree of tension necessary to produce sensation. The sailor used to the

sound of cannon can hear a person speak in a common tone during their loudest roar; and a deaf person will hear more easily while a drum is beating, or in a carriage. It equally regulates the degree of tension necessary to the action of muscular fibres, as the musician experiences by the degree of pressure suitable to the production of a given sound, from a piano-forte or an organ; and it associates motions with sensations not otherwise connected. There is no necessary connection, for instance, between a particular figure of a country dance and a given tune, since many different figures may be suited to it; but when the music begins, the accustomed movements, without any apparent exertion of volition, follow. Custom also associates different motions, though not necessarily connected; and from the habit established they cannot be performed separately. It determines the degree of force and velocity with which motions can be performed, and which, after the habit is established, cannot be violated: a blacksmith can never become a watchmaker. Custom establishes also the order in which certain sensations and motions return. An infant can soon be brought to feed only at regular hours; and those who retire regularly to the garden immediately after breakfast, will feel little or no inconvenience should their breakfast be delayed for an hour or two. The same call will also regularly return with almost every change of the constitution in other respects.

These motions, established and associated by custom, are sometimes broken with difficulty, and occasionally with injury to the constitution. If the supply of food, or the discharge of the excretions, be not obeyed, the call will often not again recur till the next period, and the feelings be uncomfortable in the interval. Indeed, the deprivation of the most trifling accustomed gratification frequently injures the health, while the most discordant noises, the most offensive smells, or the most disgusting objects, lose every displeasing effect from habit. It was this which occasioned the ancient sage to remark, "*Optimum vitæ genus eligito, nam consuetudo facit jucundissimum.*" *Choose the best occupation, for custom will make it the pleasantest.* On the other hand, these accustomed associated motions constitute the most obstinate diseases. Intermittent fevers, epilepsies, comata, &c. when the periodical return is established, are most difficult of cure. In such circumstances we cannot often succeed without stopping all motion, to begin again a new and more salutary series.

CONSUMPTIO, (from *consumo*, to waste away). See PHTHISIS.

CONTABESCENTIA, (from *contabesco*, to pine or waste away). See ATROPHIA.

CONTAGIO, (from *contingo*, to meet or touch each other; vel *infectio*, from *infectio*, to infect). CONTAGION, or INFECTION.

It has been lately attempted to distinguish these two words, though not with a happy discrimination. We should approach more nearly to common language, if we employed the adjective "infectious" to diseases communicated by contact; for we *infect* a lancet, and we catch a fever by *contagion*. In the present state of our knowledge of the subject we must perhaps employ these terms as synonymous, though we shall, in general, follow the distinction now suggested.

Contagion, then, exists in the atmosphere; and we

know distinctly but of one kind, viz. marsh miasmata, which probably consists of inflammable air. All moist earth seems to be also injurious; and we now know that moistened earth absorbs the oxygen, and leaves, of course, the azote. Putrefying vegetable and animal substances have also been accused, particularly of producing the yellow fever of America; and there is no doubt of their being highly pernicious, though from what kind of exhalation we cannot say: mineral exhalations seem never to have produced fever. Another kind of contagion is that which produces the epidemic catarrhs; others which occasion the plague, the dysentery, the cynanche malignata scarlatina, Egyptian ophthalmia, &c. but these we need not anxiously enumerate, as their nature is obscure; and the security, if it can be obtained, rests only on the general principles of avoiding cold, damp, night air, and whatever checks perspiration or debilitates the nervous system. The fevers which may arise from moistened earth cannot be avoided; but those from marsh miasmata we may escape, by choosing a situation where the prevailing winds do not blow from neighbouring marshes; or, at least, where the winds at the period the marshes emerge from under the water, the only time of considerable danger, are not frequent from that quarter.

Many of the diseases above mentioned are "*infectious*" also; and though it has been lately the fashion to deny contagion or infection, yet numerous are the victims that have been sacrificed to this pernicious system. The plague may still be pronounced eminently infectious. The small pox, the measles, the yellow fever, the ulcerated throat, the scarlatina, catarrhus epidemicus, and the hooping cough, are probably so, in a decreasing ratio, according to the order. Others, less infectious, require somewhat of more immediate contact. The dysentery, perhaps, connects both classes: then follow the itch, the siccens, and the venereal disease; perhaps the yaws. Other complaints supposed to be infectious, are apparently so from their being the offspring of contagion only.

We have omitted in this enumeration the jail and hospital fever, as of doubtful origin, partaking both of infection and contagion. The miasmata are undoubtedly diffused through hospitals, jails, and transports; but the diseases usually received from the human body, or the recent effluvia, give activity to the contagion before introduced. Thus we find a person, apparently without fever, coming from an infected hospital or jail will convey the disease, while he himself, having constantly imbibed the poison, is habituated to it; and the infection requires an exciting cause, or the effluvia in a more active state.

Contagious or infectious matter acquires peculiar virulence from confinement, especially with woollens or cotton; and in this way infection is diffused from distant countries. The last plague which infested the town in which we now write arose from a traveller remarking to his companion that, in a former journey, he had the plague in the room where they sat. "In that corner," said he, "was a cupboard, where the bandages were kept: it was now plastered; but they are probably there still." He took the poker, broke down the plastering, and found them. The disease was soon disseminated and extensively fatal.

People are very variously susceptible of infection.

The slightest breath will sometimes induce the disease, while others will daily breathe the poisonous atmosphere without injury. We remember a young lady having a violent fever in a boarding school. Each scholar constantly passed the door of her room, and no one caught the disease. When recovered, she was removed, with fresh clothes, to a lodging, where there was no communication with the persons of the house; but two young women, of the latter, were soon affected with a similar fever, and narrowly escaped. We mention this fact, not to alarm, but to induce the extremest caution, particularly in those who have previously lived in perfectly wholesome air.

The period at which the disease takes place subsequent to infection, is different in different circumstances. Should a case of fever occur within a few hours after a person has been exposed to it, the fever will assume the contagious type. Generally speaking, however, most febrile infections appear active from about ten to fourteen days. The period is scarcely ever less than seven, or more than twenty-one days. Infection is, indeed, more often taken than is supposed. A slight shiver is followed by perspiration, by a diarrhoea, or some other spontaneous discharges, and nothing more is heard of the fever. But its nature is shown by prostration of strength, want of appetite, &c.; which continue, at least, during the first septenary period, if not to the fourteenth day. It is generally received with the air in breathing; but its effect is felt at the back of the fauces only, and from thence in the stomach.

During the progress of contagion, and while exposed to infection, cold chills, indigestion, and the depressing passions, should be as much as possible avoided. The sick room should be kept well ventilated, and the discharges immediately removed: it should be also frequently exchanged for free open air; the mouth and throat gargled with oxymel, a decoction of bark, rendered pungent with spirit of vitriol or port wine. We had almost said brandy, which we once saw recommended in a very respectable scientific journal, the Critical Review, and have since used with some success. But that author was violently reprehended by a gentleman, "scrupulous," perhaps "over much," as encouraging dram drinking. We may, at least, *pace tanti viri*, recommend it to those who have no propensity to that pernicious custom. A decoction of bark, taken two or three times a day, with a few glasses of port wine, may be useful, when infection is around; and an attention to the state of the bowels is essentially necessary. But nothing will effectually preserve without air—free open air.

Fevers, however, caught by recent infection are mild, compared with those which arise from contagion long pent up, styled *fomites*; and, in our experience, very few such fevers have been fatal. There are other means proposed of guarding against infection. To persons exposed to it, camphor worn in a bag on the stomach has been recommended. We know not its efficacy; but recollect a late recorder of London (serjeant Glyn) mentioning his having worn it in the earlier period of his appointment, but afterwards disusing it. He added, that he thought himself cooler in court since he had rejected it. Another mode of avoiding infection is, fumigations with vinegar and the mineral acids in the form of air. Vinegar has been frequently employed;

but the discovery of the power of the mineral acids is contested. The late Dr. Johnson, of Kidderminster, evidently first proposed this method; but from his *publications* there appears to be no evidence of his having employed the acid gases. It seems, however, from his manuscripts, that he had done so; and, indeed, the ease with which it could be tried is a strong evidence that he had really used it. Dr. C. Smyth, who received a parliamentary reward for this supposed discovery, seems to rest his claim, in a great measure, on his having substituted the nitrous gas, since the muriatic is so offensive to the organs of respiration; but certainly, previous to Dr. Smyth's application to parliament M. de Morveau had recommended similar trials. We mean not to decide hastily or rashly; but, though the casual notice of this plan by Dr. Johnson is certainly anterior to the hints of any other author, yet to our recollection, M. de Morveau preceded Dr. Smyth. Our countryman may not have borrowed the hint; but, in the present state of chemical science, it lay too much on the level for any one to plume himself greatly on the discovery. The method of preparing each gas is extremely simple; and consists only of adding the sulphuric acid to nitre, or sea salt, deprived of their water of crystallization.

We have omitted mentioning vinegar, as it connects the former with some other modes of destroying infection. The volatility of the acetous acid adapts it for this purpose without any preparation; and it is probably highly useful, though perhaps less efficacious than the gases of the mineral acids. It is used in another form, viz. in a highly concentrated state, with aromatic oils. The first idea was taken from a preservative, said to be employed by four thieves, who plundered the victims of the plague with impunity, secured by the aromatic vinegar. It is prepared with great elegance and efficacy by Mr. Henry, of Manchester, and sold under his name.

A more recent plan of this kind is the *disinfecting bottle* of M. de Morveau. The materials are preserved in a bottle made of strong glass, secured in a wooden case, and the stopper kept down by a screw. In this glass about eleven French drachms of finely powdered black oxide of manganese are put; and to these are added about three ounces by weight, of pure nitric acid of the specific gravity of 1.40, with an equal bulk of muriatic acid, of the specific gravity of 1.134. About two thirds of the bottle must be empty: it is covered with a plate of glass, which is raised by a single turn of the screw. This plate must be ground and polished, so as to close the bottle accurately, and every particle of dust must be carefully wiped off. When used, it must not be held near the nose, as the pure oxygen gives pain when respired; but in a few minutes it will fill a large room with the gas. These materials, if the bottle is opened daily, will last six months. The price, when properly filled, is, in Paris, twenty one francs for each. *Annales de Chimie*, vol. lii. p. 347.

M. Dumotiez prepares bottles of a smaller size, with less proportions of the same materials. The chief improvement is, that a small aperture is made by a turn of the screw. They are cheaper, and adapted for apartments of a common size.

When infection or contagion has taken place, an emetic is the first necessary step; and this should be followed by active purging. After these medicines, a

warm cordial diaphoretic, and sometimes a blister, is necessary. If, however, any one medicine is peculiarly and essentially requisite, it is the cathartic; but the emetic must be premised. The reasons for this plan will be afterwards explained.

Mineral exhalations have been sometimes supposed to be causes of fever; but we have not found any well authenticated instances of such effects, though Dr. Webster, in his History of Epidemics, has endeavoured with great earnestness to connect epidemics with volcanic explosions, and other physical phenomena. Those who work in mines of lead or quicksilver are, however, subject to nervous colics and palsies.

CONTAGIO'SI, (from *contagio*, contagion). Disorders from infection or contagious diseases.

CONTEMPERANTIA, (from *con* and *tempero*, to moderate). See TEMPERANTIA.

CONTE'NSIO, (from *contineo*, to restrain). It sometimes is used to express a tension or stricture.

CONTE'NTA, (from *contineo*, to contain). CONTENTS. Any fluids contained within a solid part of the body.

CONTE'NTUS, (from *contendo*, to stretch). STRETCHED.

CONTINE'NS FE'BRIS. A CONTINUAL or a CONTINENT FEVER, which proceeds regularly in the same tenor, without either intermission or remission. This rarely, if ever, happens. See FE'BRIS.

CONTINUA FE'BRIS, (from *continuo*, to persevere). A CONTINUED FEVER, attended with exacerbations, and slight remissions, but no intermission; sometimes called *assidua*. See FE'BRIS.

CONTO'RSIO, (from *contorqueo*, to twist about). CONTORSION. In medicine this word hath various significations. See ILIACA PASSIO, LUXATIO, LUXATION OF THE VERTEBRÆ and CAPUT.

CONTO'RTUS, (from *contorqueo*, to twist aside). In botany it means ravelled, curled, or twisted.

CONTRA APERTU'RA, (from *contra*, against, and *aperio*, to open). A COUNTER OPENING. This is sometimes necessary in wounds made by puncture, or by a bullet, to discharge what is contained in them, or to prevent their growing fistulous. The circumstances requiring this procedure are so various, as to demand considerable sagacity in the surgeon. The opening is sometimes made by passing a trochar to the bottom of the wound, directing its point to the nearest skin, and continuing it through, so as to make the old and the new aperture one continued passage; more frequently by cutting through the skin directly upon the intruded body, or upon the button of the probe, which may be introduced to the bottom of the wound to direct the incision. See Petit and Heister's Surgery.

CONTRACTU'RA, (from *contraho*, to draw together). CONTRACTION; called by Dr. Aitkin, *beriberia*. An immobility of any of the joints from a preternatural contraction of some of their muscles, or from a derangement of the osseous or ligamentous parts of the joint affected. Dr. Cullen ranks this as a genus of disease in the class *locales*, and order *dyscinesia*; and defines it "a continued, rigid contraction of one or more of the limbs." He distinguishes two species.

1. CONTRACTU'RA PRIMARIA, from a rigid contraction of the muscles, termed also *obstipitas*; a word,

that with any other annexed distinguishes the variety of the contraction.

Of this species he forms four varieties. 1st. When the muscles become rigid from inflammation. 2d. From spasm. 3d. When contracted, from the antagonists being paralytic. 4th. From irritating acrimony.

2. CONTRACTURA ARTICULARIS, from rigid joints.

Dr. Aitkin observes, that the disease is most frequently symptomatic: and when it depends on muscular contraction only, he advises the tepid bath, with bandages, and counteracting by proportional weights the increased power of the muscle. Mechanical contrivances, either to assist the paralytic muscles or gradually extend the contracted ones, are chiefly useful. In each instance, the vapour bath is a valuable assistant. Dominiceti Buzaglo, and at present Mr. Pugh, have often succeeded in this disease by a bath of this kind.

CONTRA-FISSURA, (from *contra*, *opposite*, and *findo*, *to cleave*). CONTRA-FISSURE. See FISSURA.

CONTRAHE'NTIA, (from *contra*, *to contract*). Medicines which shorten and strengthen the fibres.

Astringents are the only medicines of this nature, q. v. CONTRA-INDICA'TIO, (from *contra*, *against*, and *indico*, *to show*). See ANTIDEIXIS.

CONTRA-LUNA'RIS, (from *contra*, and *luna*, *the moon*). An epithet given by Dietericus to a woman who conceives during the menstrual discharge; but we believe there is no instance of this kind.

CONTRARIUS. CONTRARY. In botany it means not parallel in situation. In medicine, any thing opposite in its nature or tendency.

CONTRA-VE'RMES, (Sem.). See SANTONICUM.

CONTRAYE'RNA, (from *contra* and *yerva*, *a herb*, Spanish). A herb good against poisons. *Drakena*, *Cyperus*, *longus odoratus Peruanus*, *dorstenia*, *bezoardica radix*. COUNTER POISON. It is the *dorstenia contrayerva* Lin. Sp. Pl. 176.

The contrayerva was first brought into Europe about the year 1581 by sir Francis Drake, whence its name *Drakena*. It is the root of a small plant found in Peru, and other parts of the Spanish West Indies. There are two kinds; the one *placenta ovali*, the other *angulari et undulata*. The sort generally brought to us is about an inch or two long, half an inch thick, full of knots, surrounded on all sides with numerous long tough fibres, most of which are loaded with scaly knobs, of a reddish brown colour on the outside, and pale within.

The tuberous parts of these roots are the strongest, and should be chosen for use. They have an agreeable aromatic smell; a rough, bitter, penetrating taste; and, when chewed, they give out a sweetish kind of acrimony.

It is diaphoretic and antiseptic; formerly used in low nervous fevers, and those of the malignant kind; though taken freely it does not produce much heat. It is, however, now seldom used; though, with the Peruvian bark in decoction, we have sometimes employed it in ulcerated sore throats as a gargle.

Dr. Cullen observes, that this and *serpentaria* are powerful stimulants, and both have been employed in fevers in which debility prevailed. However, he thinks, wine may always supercede the stimulant powers of these medicines; and that debility is better remedied by the tonic and antiseptic powers of cold and Peruvian bark, than by any stimulants.

By the assistance of heat, both spirit and water extract all its virtues, but they carry little or nothing in distillation; extracts made by inspissating the decoction retain all the virtues of the root.

The London college forms the compound powder of contrayerva, by combining five ounces of contrayerva in powder, with a pound and a half of the compound powder of crabs' claws.

This powder was formerly made up in balls, and called *lapis contrayervæ*; employed in the decline of ardent fevers, and through the whole course of low and nervous ones. The *radix serpentaria Virginensis* in all cases may be substituted for the contrayerva. See Lewis's *Materia Medica*; Neumann's *Chem. Works*; Raii *Hist.* and Cullen's *Mat. Med.*

CONTRAYE'RNA NO'VA, or MEXICAN CONTRAYERVA. It was introduced into Europe after the former, and is brought from Guiana, as well as from Mexico. The root is longish, about two fingers thick, externally rough, and of a brownish colour, internally white, with a pith in the middle, of a sweetish aromatic taste, and but little inferior to the contrayerva introduced before it. This is the root of the *psoralea pentaphylla* Lin. Sp. Pl. 1076.

CONTRAYE'RNA A'LEA. CONTRAYE'RNA GERMANO'RUM. See ASCLEPIAS.

CONTRAYE'RNA VIRGINIA'NA. See SERPENTARIA VIRGINIANA.

CONTRI'TIO, (from *contero*, *to break small*). See COMMINUTIO.

CONTU'SA, (from *contundo*, *to bruise*). *Contusio*, *collisio*, *phlosma*. CONTUSED WOUNDS, CONTUSIONS, or BRUISES. When any part is bruised, the small blood-vessels are broken, and the blood they contained, effused in the adjoining cellular membrane; or these vessels lose their tone, and no longer contributing to the circulation, their contents stagnate. In either of these cases, if the impediment is not removed, an inflammation comes on, followed by suppuration, sometimes by gangrene. There are also peculiar symptoms from any injury done to a nerve, a blood vessel, or a bone.

In general, the symptoms consequent on bruises may be reduced to three classes.

First, They arise either when the solids are destroyed, and the fluids they contain discharged: those functions are consequently abolished which depend upon a due and determinate motion of the fluids through the sound vessels.

Secondly, The discharged fluids, collected either in the natural or preternatural cavities of the body, by their bulk and quantity press upon the adjacent parts, and either totally destroy or at least disturb their respective functions.

Thirdly, The humours thus discharged, may, by their continuance and stagnation in their cavities, acquire such a degree of acrimony as to corrode and destroy the adjacent parts.

When the internal parts are bruised, and the external integuments are entire, or confine the extravasated fluid, the consequence is, 1. An echymosis. 2. A spurious aneurism. 3. A sugillation. 4. Ulcers and gangrenes. 5. Caries; or, 6. Scirrhus.

Boerhaave observes, that contusions on fleshy parts may produce suppuration, gangrene, palsy, or a contraction. On a large nerve, a palsy, atrophy, incurable insensibility, and a gangrene on all their parts below

the injured part: this may peculiarly follow contusions of the spine and its marrow. Contusions of the viscera, he justly observes, are often speedily fatal; they are tender; and their vessels easily burst.

Contusions from gun shot wounds are dangerous from the destruction of the organized parts which are bruised, as well as from the general concussion that the whole body suffers from the air violently impelled against it. The effects of concussion we have already noticed, though we have been unable to explain them. In no case should we be more cautious of pronouncing on the event of any disaster, than where a concussion or a contusion happens; and where both may have occurred, the caution, if possible, should be greater. See Bohnius de Renunciatione Vulner. § 2. cap. 1.

When bruises are received inwardly, it is not easy to judge readily of the extent of the injury done by them; and when the case becomes more manifest, it is often too late to attempt relief. See CONCUSSION.

The remedies must be those chiefly which, by their stimulus, restore the tone of the vessels. For external use, where the skin is not much destroyed, a mixture of sharp vinegar, with twice its quantity of water, may be applied frequently by means of linen cloths wrung out of it, and, as often as they dry, moistened again. If there is much inflammation present, the following, called *embrocatio ammoniæ acetatæ cum saponæ*, ACETATED AMMONIATED EMBROCATION WITH SOAP, is very useful. R. Aq. Ammoniæ, acetatæ solutionis saponis añ ʒ. 1. m. But where the inflammation has subsided, two drachms of aqua ammoniæ puræ added to the above is considered as very efficacious. Spirituous applications should not be used, except where the sole intention is to strengthen the injured fibres immediately on the occurrence of the accident; in slighter cases, a small quantity of spirit may be mixed with vinegar, and used on the first reception of the bruise. Even such friction as the bruise will bear on the part, or around it, will be generally useful. See DISCUTIENTS.

If the bruise is considerable, and particularly if any internal part is affected, bleeding, a cooling liquid diet, with repeated gentle purgings, are of the greatest advantage. If the bruise is in the lower belly, clysters are necessary; and where the internal parts are greatly affected, leeches or blisters, as near the seat of the complaint as can be admitted, are useful. Poultices, which were formerly applied to carry on the circulation by relaxing the over distended vessels, are now disused, as they are found to promote suppuration. Cold vinegar poultices act as stimuli; but cold, in the other forms, is seldom admissible, as the vessels are too weak to restore the action. This remedy is, however, useful in relieving the weakness which is often the consequence.

The advantages of the tinct. opii externally as a resolvent, of Dover's powders, and the anodyne antimonial drops, recommended in the article CONCUSSIO, deserve the same attention when contusions happen, and on the same principles.

See Bohnius de Renunciatione Vulnerum; Van Swicatan's Commentaries on Boerhaave's Aphorisms; Tissot's Advice to the People; Bilguer's Dissertation on the Inutility of amputating Limbs, p. 69, 73. Bell's Surgery, vol. v. 446.

CONTU'SIO, CONTUSU'RA. See CONTUSA.

CO'NUS. (Greek.) A CONE. The fruit of the pine, fir, or cedar tree; or any fruit with a broad basis, which gradually diminishes to a point. The trees which bear such fruit are called *coniferous*. Dioscorides says, that *κωνος* is a name of liquid pitch.

Co'nus fuso'rius, also called *pyramis*. A CONE. It is a vessel resembling an inverted cone, made of brass or iron, and is used for separating a regulus from its scorix; for while the fused metal is pouring into the crucible, it is struck with a mallet, in order to produce a tremulous motion in it, by which the heavier parts fall to the bottom.

CONVALESCENCE, (from *convalesco*, to grow well). This state implies a recovery from disease, when nature, with little assistance, is supposed capable of restoring health. In all acute diseases, considerable attention is, however, requisite, to prevent a relapse. On recovery from fever, the appetite often returns before the powers of digestion, and, of course, cannot be always safely indulged. In recovery from other diseases, the principal complaints should be cautiously kept in view. Thus, after peripneumony, the expectoration should be anxiously kept up; after enteritis, the constant action of the bowels; after affections of the head, the utmost tranquillity of the body and mind preserved. In short, convalescence requires, in almost every situation, care equally unremitted with that which the continuance of disease demanded.

CONVALLA'RIA, (from *convallis*, a valley). See LILIUM CONVALLIUM.

CONVALLA'RIA, POLYGONATUM. See POLYGONATUM.

CONVOLU'TUS, (from *convolvere*, to roll round). In botany it means rolled up, like a scroll of paper.

CONVOLU'TA SUPERIO'RA, et INFERIO'RA O'SSA, (from *convolvere*, to roll round). See CONCHÆ NARIUM SUPERIORES, and INFERIORES.

CONVO'LVULUS, or VOLVULUS, (from *convolvere*, to roll together). (See ILIACA PASSIO.) It is also the name of a genus which affords the JALAPA, MECOACHANA, TURBITH, and SCAMMONY; q. v. The whole genus usually abounds with plants containing a milky juice strongly cathartic and caustic.

CONVO'LVULUS SEPIUM, Lin. Sp. Pl. 218. It is the *c. major albus* of authors, and resembles, in its virtues, the scammony.

CONVO'LVULUS SCOPARIUS, a new species, vide Lin. Supplem. 135. Aiton's Kew, vol. i. p. 213. Willdenow, vol. i. p. 872. Probably the plant which affords the lignum rhodium.

CONVO'LVULUS COLUBRI'NUS. See PAREIRA BRAVA.

CONVO'LVULUS I'NDICUS RADI'CE TUBERO'SA E'DULI, CO'RTICE RU'BRO. POTATOES. See BATTATAS HISPANICA.

CONVO'LVULUS MARI'TIMUS. See BRASSICA MARI-TIMA.

CONVO'LVULUS MARI'TIMUS ZEYLA'NICUS, &c. See BINTAMBARU ZEYLANENSIBUS.

CONVO'LVULUS CANTA'BRICA, CONVO'LVULUS SPI'CE FO'LII, CONVO'LVULUS LI'NARIE FO'LIO. See CANTA-BRICA.

CONVO'LVULUS SOLDANE'LLA. See BRASSICA MARI-TIMA.

CONVO'LVULUS SYRI'ACUS. See SCAMMONIUM.

CONVO'LVULUS PERE'NNIS. See LUPULUS.

**CONVUL'SIO.** A CONVULSION, or involuntary contraction of the muscles, (from *convello*, to pull together). Called also *hieranosos*, *distensio nervorum*.

Dr. Cullen places this genus of disease in the class *neuroses*, and order *spasmi*; and defines it, "an irregular clonic contraction of the muscles without sleep," of which he enumerates nine idiopathic species; and five symptomatic. See *Nosologia Methodica Synopsis*, p. 216, vol. iii.

Under the *spasmi* Dr. Cullen includes the tonic and the clonic spasms, where the muscles are rigidly and immovably contracted; and where the violent, irregular contractions are alternated with equally sudden relaxations. This arrangement is formed with the strictest propriety, as we shall afterwards find.

Convulsions attack persons of all ages, but chiefly the young, or the debilitated; all constitutions, but principally the fair, the delicate, and the irritable; each sex, but particularly females. Its causes are various; but the chief source of convulsions is, in the opinion of every author, irritation. It is certainly irritation, in systems peculiarly mobile, in other words, easily excited to action; but, as the mobility is greater, the irritation necessary to produce convulsions is less; and sometimes so slight as to be imperceptible.

If we examine the functions of the nervous system, we shall find life and health depend on the regular distribution of the nervous power. If it is hurried, irregularly exerted, or deficient, various diseases, and particularly convulsive ones, ensue. Joy, grief, surprise, will equally produce them. Violent exertions, and tone, suddenly relaxed, are also causes of these irregular motions. We do not find, however, that with high health, full vessels, and a firm constitution, however the circulation is accelerated, or the nervous power excited, convulsions ensue, unless the tone is suddenly remitted. Whatever effect therefore may be attributed to predisposition, the causes are chiefly debilitating ones; and the constitutions chiefly affected, those which are weak. It is then irregular action, in weak habits, which constitutes the disease. In palsies of every kind, tremors attend every exertion; and the various species of tremor in Sauvages', one only excepted, are obviously from debility. In hysteria there is usually considerable debility, though the circulating system is often full; and indeed there is no more common cause of weakness than over distended vessels. This is the exception noticed in Sauvages' species of tremor. In epilepsy this debility is less obvious, but the most obstinate cases occur in weak constitutions; and, in others, the irregular action is excited by peculiar and violent stimuli, chiefly affecting the organic structure of some part of the nervous system. The palpitations in chlorosis, the gesticulations in chorea, the convulsive agitations in raphania, the causes of true convulsive asthma, all confirm the idea, that debility is the cause of irregular action. Nor need we add, for it is the subject of common observation, that convulsions close the scene, particularly of disorders induced by excessive evacuations and worn out constitutions; that they are effects of narcotics of every kind, of deleterious gases, mineral exhalations, and even of stimulants that exhaust the vital power, and increase, in consequence, the irritability. We may therefore rest safely on the position, that irregular action, either spasmodic or clonic, has its foundation in debility or in irritability; but the former

is most frequent, as it is a very common cause of increased mobility.

From the effects of narcotics, of deleterious gases and similar powers, we have reason to conclude, that irregular action may arise from debility alone, or at least from obscure and unperceived irritation. Yet in practice we must always keep in view the existence of irritation; and we often find it necessary to check this exciting, at the risk of increasing the power of the predisposing, cause. There is little doubt, for instance, that the irritation of the meconium sometimes produces the locked jaw and convulsions in new born infants; this must be evacuated. The sedative power of lead produces the Poitou colic: this irritation must be soothed by opium before laxatives will succeed. A wounded nerve will occasion a locked jaw; the irritation on the nerve must be removed by destroying its sensibility, and the increased action of the muscles at the same time counteracted by appropriate remedies, general and topical. Other convulsions are more effectually remedied by warm stimulants and tonics: the warmest stimulants are often required in the convulsions from sedative poisons or the deleterious gases. In this short disquisition, our first object was to establish the principle, that convulsions are rather *irregular* than *increased* action, and that their primary cause was debility: our second, not to mislead the young practitioner, who, by attempting to counteract debility, may lose sight of the exciting cause, irritation.

How debility acts in producing convulsions we pretend not to say, nor is the inquiry of importance; there seems, however, to be a ruling power in the constitution, which regulates the distribution of the nervous influence; and, when it is weakened, this influence is irregularly distributed. We mean not to say, with Stahl, that this power is all wise, and directs every thing for the general good; exciting these convulsions to throw off some noxious matter, threatening destruction to the whole system. If such a power exists, it is implanted by the Almighty; regulated according to his fiat by secondary causes; and acting necessarily from the organisation of the machine. In another view, the whole nervous influence may be regulated by its state in the brain; and, if that arrangement is altered by any violently stimulant or sedative impression, the rest must suffer a similar change: and, when we contemplate the various phenomena which diseases of the nervous system present, we are rather inclined to adopt this opinion. We have, however, already observed that our object is to establish principles, not to build systems.

Sometimes convulsions attack suddenly, without any warning; at others their approach is indicated by certain symptoms, such as coldness of the feet, or a sense of creeping, rising like a blast of cold air from a particular part of the extremities to the head; the left hypochondrium is sometimes affected with tensive and flatulent pains, and a costiveness attends; the urine is thin and pale; tremors and various unusual sensations are perceived, and in different patients other symptoms also attend, as the prelude to more violent ones. During the fit the motions are violent and involuntary, continuing in different cases for a longer or shorter period, and returning after different intervals, occasionally after regular intermissions. Languor, delirium, sleepiness, vomiting, or headach sometimes follow the cessation of a convulsive

paroxysm; but there are cases in which little or no sensible uneasiness is perceived on recovery from it.

Infants when disposed to convulsions are affected with a cough, vomiting, or diarrhœa; their features are at times distorted; a blueness appears about their eyes and upper lip, and twitchings or startings are often observed, particularly a contraction of the fingers into the palm of the hand; and during the intervals of the fits they are drowsy. As death draws nigh, the convulsions are more frequent.

Convulsions, however, which have appropriate names will occur in the different articles. It is now only necessary to mention the species included by Dr. Cullen under the genus *convulsio*. The nine idiopathic species differ only from their causes, where there is any real distinction; for the "universal," the "habitual," the "intermittent," convulsions are varieties only, and the symptomatic convulsions are less objects of particular attention. The result is, that convulsion is a symptom only, and does not deserve a particular generic distinction. There are, however, some forms of the disease so important and dangerous, that they require a more minute attention. The first of these is the *convulsio puerperarum*.

Dr. Bland thinks that convulsions in pregnant women, and during labour, have nothing peculiar in their cause from those which happen to women differently situated; and though external agents, particularly violent affections of the mind, may sometimes, as at other periods, excite them, yet this will rarely happen, unless there is some peculiar vice in the constitution disposing to them. From observation he thinks he is justified in saying, that the puerperal state is far from favouring them; as women at that time will do and suffer, almost with impunity, what at any other would be attended with the most serious consequences. But whatever may be the cause, he observes, there is evidently in the fit, as in the apoplexy, a too rapid and dangerous determination of the blood to the head, which demands the most immediate and serious attention. To remedy this, blood must be immediately drawn, and, if possible, from the jugulars. The state of the labour should then be inquired into; and if the child is not too far advanced in the pelvis, it will be right to prescribe a large stimulating clyster to empty the bowels, and at the same time lessen the determination to the head; this, if not sufficient for the purpose, should be assisted by a few grains of jalap and calomel, or some other brisk purge. If the labour is far advanced, the convulsions will act upon the fœtus; and if there is no impediment, either from wrong presentation or disproportion of the child to the pelvis, will, in a little time, safely expel it. If any obstacle to delivery is found, the position of the child, if faulty, must be altered; or we ought to have recourse to other necessary assistance, in the same manner as if convulsions were not present. In either way the termination of the labour will frequently put an end to the convulsions. But if this is too hastily performed before the vessels have been properly emptied, and the rapid motion of the blood in them diminished, there will be danger, from the torrent rushing too impetuously into the intestines or other abdominal viscera, of inflammation in some of those parts, inducing puerperal fever, and often death. But where the labour is not far advanced, after the exhibition of the clyster and purgative,

thirty drops of the tinct. opii may be given, and repeated, interposing occasionally the clyster or cathartic, as symptoms shall indicate. See Dr. Bland's Essay on the Treatment of Convulsions during Parturition.

Though we, however, allow Dr. Bland's authority to merit every attention which his judgment and long practice demand, we think that convulsions of puerperal women are really connected with that state. They occur to those who never otherwise have been affected with the disease; and they cease when labour pains force down the child, as if its pressure on some of the nerves of the pelvis had occasioned the irritation. The necessary doses of opium also are much larger than he recommends, and even ten grains of solid opium may be given in a clyster. We have seen half a drachm ordered. Dashing cold water in the face has sometimes succeeded, according to Dr. Denman's recommendation, and the foxglove, according to Dr. Hamilton's; but the chief object is to hasten delivery. In every other respect, Dr. Bland's directions appear to us highly judicious.

Convulsions are sometimes a symptom attending fevers, and may be produced by inanition, as when hæmorrhages or diarrhœa have occurred; or by repletion. Relief will most readily be procured by evacuations from the bowels in the last case; and by antispasmodics, particularly opiates, in the former. When they are caused by wounds, warm oil, or the warmer balsams, applied to the injured part, often effect a speedy cure, when stricture in the part has been previously relieved by manual operation: the causes of irritation are indeed various, and therefore different means will be required to effect this end.

Convulsions in children, from teething, require the loss of blood, particularly if the gums are swelled and painful. When depletion is the cause, cordials must immediately be administered, and a generous nourishing diet allowed.

If, as we have said, plethora is a cause of debility, suppressed evacuations, which also occasion it, become a source of irritation. The repulsion of cutaneous diseases, of the hæmorrhoidal discharge, sometimes of the menses, are therefore frequent causes. In such cases, some evacuation is necessary; but so much only as will take off the immediate effects of the plethora. The other remedies must be adapted to the local fulness; these are chiefly laxatives, diaphoretics, and aloetic medicines, interposing in every instance opium, and, in the uterine obstructions, opium with camphor.

Convulsions in children are owing to irritation of almost every kind; to flatulence; to the irritation of the gum distended by teeth; to acrimony in the stomach and bowels, or worms. In every such instance we must guard against the peculiar irritation, as it occurs to our notice. The stomach and bowels must be certainly kept clear, and opiates then administered, either by the mouth or by clyster. When flatulence is apparently the cause, to the opium in a clyster, the asafœtida should be added. Worms are a more important source of irritation; but all children have worms: and if symptoms of irritation continue after rhubarb and calomel have been repeatedly given, worms may be fairly accused as a cause, and medicines for this purpose employed. Not to anticipate what will be the subject of more particular consideration, we may now add, that the bear's foot, the hel-leborus fœtidus, is the only certain remedy.

The more general remedies for convulsions are musk and the whole tribe of fetids. These seem to act as sedatives, or rather as *irritants*, a class of medicines whose nature we shall explain under that term. Warm bathing appears to relieve in a similar way. Nor can we attribute the effects of valerian to any other power. The union of the valerian with bark seems to give it an additional efficacy, from some influence which we cannot explain. The remaining observations on the remedies for convulsions have been anticipated in the article ANTISPASMODICS; q. v. See also SPASMS.

CONVULSIO IN'DICA. See TETANUS.

CONVULSIO A N'RV I PU'NETURA. See TRISMUS.

CONVULSIO RAPHA'NIA, SOLONIENSIS, et AB USTILAGINE. See RAPHANIA.

CONVULSIO U'TERI. See ABORTUS.

CONY'ZA, (from *κονις*, *dust*; because the powder is sprinkled to kill fleas in places where they are troublesome). FLEA-BANE. The leaves of this plant are commonly glutinous and strong scented, the cup of the flower generally scaly, and of a cylindrical form. The flowers consist of many florets, which are succeeded by seeds covered with a downy substance.

CONY'ZA ÆTHIOPICA. See ELICHRYSUM.

CONY'ZA MA'JOR VULGA'RIS. *Mas Theophrasti, conyza major* Diosc. GREATER FLEA-BANE. See BACCHAR.

CONY'ZA MI'NOR FLO'RE GLOBO'SO, *pulicaria, conyza minima, et media*. SMALL FLEA-BANE. See INULA DYSENTERICA.

The chief use of all the flea-banes is to destroy fleas and gnats by burning.

COOKERY. (See ALIMENT, page 72.) Though in this article we have, perhaps, introduced all the more essential remarks, yet we must still add what fancy, fashion, or refinement, has suggested. It is not generally understood how profuse and prodigal civilized nations are in the expenditure of aliment. A large proportion escapes unchanged, and becomes, with the excrementitious fluids, a manure. Many substances, rejected as useless, are employed in the same way. We shall begin with the latter.

Fish, when caught in a proportion beyond that which the inhabitants can consume or preserve, are scarcely objects of the present attention; but the bones, which we reject, after the modern processes of cookery still contain useful aliment. When ground, they yield gelatine to the common processes. The stomach of dogs extract it, so that they discharge almost pure calcareous earth. Later refinements have extracted nutritious particles from bones, by an instrument styled a digester, and, from its inventor, Papin's digester; in which water, in a strong well secured iron vessel, is heated far beyond the boiling point. The fins of fish, some parts of the skin, have been in a similar way dissolved.

Boiling in close vessels has been recommended by some authors, as preventing the evaporation of the finer parts, or what may be styled the aroma of animal food. This is, however, an useless refinement; for this aroma is soluble in water, if not carried off by too great heat. To preserve it, the water should be kept immediately below the boiling point, and the process longer continued. This makes beef, mutton, and chicken tea, superior to the broth of either; and, if we would be still

more nice, the meat should be put in a close earthen vessel without any water, and placed in a water bath, at about 200° of Fahrenheit. It is stewed in the steam raised from the food; and the jelly, thus formed, contains the more delicate and nutritious particles of the food, with the flavour unimpaired and unaltered. In this state it is well adapted for delicate stomachs, and for food in febrile cases. When, as in baking, the volatile parts are not closely confined, they are altered by heat, and acquire a kind of empyreuma not agreeable to the taste, nor easy in the stomach. In the common ovens, this compound, empyreuma, is often very offensive.

The great refinement of modern cookery is, however, the minute division of the aliment. In this consists the real secret of the effects of the soup prepared according to count Rumford's plans; which are only the decoctions of the farinacea, with a proportion of animal food, deprived, by the continuance of heat, of all their nourishment, which is communicated to the water. To this various condiments are added; of which the cheapest and most useful is the red herring, more often used in the soups of the luxurious than they are themselves aware. It is an instance of what we remarked in the condiments of the ancients, of the effects of even unpleasant substances in a very minute proportion.

COOPE'RTIO, (from *coopferio*, to cover over). COVERING, CLOTHING, or a SMALL CLOAK, by which the body is defended from the air, the same as *περιστολη*, *amictus*, from *περιστellein*, *co-operire*, *tegere*, to cover, in which sense it is several times used by Hippocrates. It is applied to the belly, and uterus investing the fœtus; and also to a medicament, which is placed upon the tooth, involving it like a plaster, by Scribonius.

To this article we have referred a most important subject, viz. CLOTHING in general, on which the health greatly depends, and in diseases meriting also the most scrupulous attention.

The ancients furnish little information; for their clothes were uniformly woollens, seldom probably cleansed in the washing tub. The inconvenience from this source they avoided by frequent bathing, while the limbs were anointed with oil, on coming from the bath.

Linen was unknown till after their connexion with Egypt in the time of Augustus, and then not generally used: the sericæ vestes were cotton; for the country of the Seres, the lesser Bulgaria, is unfavourable for the propagation of the silk worm, and the ancients were unacquainted with China, or any country to the east of the Gulf of Martaban. A proof of their ignorance of silk is, that in the time even of Justinian it was sold for its weight of gold. We mention these circumstances chiefly to explain the cause of the slight attention paid to this subject by the ancient physicians; for, however changeable the climate, they suffered little in consequence of their woollen dresses, which we have no reason to think were peculiarly fine or thin. In more modern periods it is a subject of peculiar importance; and, when we consider the *most modern* fashions, calls for the strictest attention.

How can you bear the access of cold air to your naked body? asked an European of a Canadian Indian. I am all face, he replied; meaning that custom had rendered it familiar. Were we in a state of nature, this reply might be satisfactory: yet we know that catarrhs

and-rheumatisms are the most constant diseases of the savage. In polished life, a more particular inquiry is necessary.

The interior clothing of the present period consists of linen, of cotton, or of flannel. The first, usually worn next the skin, must be frequently changed. The effect of frequent change is to keep up perspiration, and it was even supposed to produce emaciation. The only real inconvenience of linen is, that it absorbs moisture slowly; in other words, its hygrometrical affinity is inconsiderable, and if for a short time removed from the body after copious perspiration, it feels damp and cold. We bear, however, with this inconvenience from the comfort we feel in changing it; nor, when used only as the garment, next the skin, is it ever materially injurious.

The hygrometrical affinity of cotton is more considerable, and calico, for shirts or bed gowns, is preferable. For children, on many accounts, it is the only proper shirting. To the feeling it is warmer than linen, though less pleasant; though it equally at least promotes perspiration. In the more improved state of the manufacture of calicos, there is little distinction either in point of comfort or salubrity between them and linens; yet, in the latter view, they are on the whole preferable.

The hydrometrical affinity of flannel is still more considerable; and copious indeed must be the perspiration that makes them inconveniently damp. To this must be added, that the spiculæ of the wool stimulate the surface and excite the action of the cutaneous vessels, while the inconvenient roughness is soon, from custom, unobserved. It may now appear that we have proved little more than the superiority of flannel to calico, and of this to linen; yet, we think, we have placed their different merits on such a foundation as will elucidate many modifications of our clothing.

Our upper garments, in this climate, are generally of woollen; and, where this material is not used, we compensate by numerous folds for the thinner texture, and the increased conducting power of heat.

This last circumstance, of the greatest importance in our present consideration, we have explained in the article *CALORIC*. Air is a bad conductor of heat, and polished surfaces receive it slowly. Hair and wool, therefore, whose surfaces are polished, conduct heat imperfectly, and more so in proportion to their fineness, which occasions the more frequent interposition of aerial molecules, and their little affinity for heat. This renders the ciderdown so peculiarly warm. We did not mention the effect of this circumstance in our comparison of the internal coverings of our bodies, not to confuse it with the hygrometrical affinity, and because it is more peculiarly applicable here; but its influence will be sufficiently obvious. As conductors of heat, from the body, silk is more powerful than cotton, and cotton than woollen. Each is colder, therefore, in the same proportion than that which follows. Black also conducts heat from without better than white, and the more refrangible rays better than the less refrangible. In warm weather, therefore, these colours are warmer in the same order. Count Rumford's later refinements on this subject, are not sufficiently established to induce us to enlarge on them.

These considerations will lead us to a choice of cloth-

ing, in different circumstances, for the preservation of health. In general, we have erred by clothing ourselves too thin, and changing our dress too early in the summer. It was formerly a rule, even when the seasons were seemingly more forward than at present, to "keep the winter dress till May be done;" but we now change it more early, or adopt that of the demi-saison, which is scarcely more warm than the dress of summer. It is not, however, the real warmth which is of so much consequence, as the sudden changes of dress in the same day; not according to the change of temperature, but to fashion. The drawing-room may, indeed, be warm, but the passages which lead to the door are cold; and the modern fine lady is ill adapted for so sudden a change, either from dress or habit. It has been remarked, that consumptions have been much more frequent in Scotland since the plaid has been disused; and in England, we fear, from the present fashions, they will be still more abundant than at any former period.

It has been constantly remarked, that the breast and the feet should be carefully guarded from cold. We see sufficient reason, from theory and experience, for the latter caution; and it will not be difficult to explain the former, when we reflect, that a local chill determines the fluids to the internal parts of the same organ. Thus, chills in the breast produce catarrhs and peripneumony; in the extremities, rheumatism; in the face, coryza and ophthalmia.

The application of different kinds of clothing to different diseases, presents some variety which merits attention. In the thin emaciated habits, flannel has been forbidden. It exhausts, it is said, too much; yet these are generally susceptible of cold; and by this safeguard we avoid its most unpleasant effects. Such plans, however, should be conducted with a discriminated caution. If flannel be adopted, cold air should not be excluded, and the patient accustomed to a moderate breeze, till habit allows of greater cold with impunity. Calico should in the summer be substituted for flannel, and the period of its wear protracted annually; while in spring the flannel should be earlier thrown off. The changes, for a time, should be conducted with care; and in the height of summer the cold bath will assist this progressive improvement. In general, however, flannel does little harm if free air be allowed. Its object is to guard against the bad effects of cold air; nor should it be worn if the air is at the same time carefully excluded.

When, however, the object is to produce and continue a free discharge of sweat, flannel is essentially necessary. The "nine times dyed blue flannel" has certainly the virtues of common woollens, and no other. Flannels were formerly worn when the patient was confined to bed in fevers, in a profuse sweat, to promote concoction. At present they are employed only in rheumatisms, and occasionally in salivations. In each their utility is obvious. In fevers at present, fresh linen is usually allowed daily, and the patient feels the highest gratification from the change; and calico in this state is not equally grateful, certainly not more advantageous, except the perspiration is very profuse.

We must add, that the flannels should be frequently changed and washed. Those who would think themselves injured if they did not change their linen

daily, will often not change their flannel for months. Flannel shirts should never be worn above two or three days without being rinsed in cold spring water, and hung in open, free air.

Extraordinary warmth of clothing should be admitted with caution; and in no instance, unless it can be steadily employed. In general, it should be the object to bear changes of temperature with impunity; but this invulnerable constitution can only be gained by degrees. Those accustomed to indulgences should proceed with the utmost caution, and be aware that the attempt is highly dangerous. The cautions already suggested, will form their chief security.

Besides the clothing mentioned, modern refinement has introduced some new manufactures. The shawl, the eiderdown, and the Shetland wool, owe their peculiar advantages to the fineness of the texture, in the way already explained. The fleecy hosiery is a manufacture of cotton, where the inner surface is raised into a soft, flocculent pile. As it does not possess the stimulus of wool, we doubt if it is greatly superior to the fine soft woollens. Common consent, perhaps fashion, gives it the preference, and the dictates of fashion we shall not oppose. The fine fur of animals often covers the skin, and is peculiarly warm; but it must be employed, in health, with caution, as its disuse is dangerous. It may be an useful lesson to add, that ladies should scarcely ever change their "bosom friend." Velvets are warm from their weight, rather than their pile; plushes from both. The cause of the coldness of silks will be sufficiently obvious from their texture; but the oiled silk, or linen, is warm, from preventing all access of air, and closely confining the heat of the body.

COOPERTO'RIA, (from the same,) i. e. *cartilago thyroidea*; called also *abicum*. See ASPERA ARTERIA.

COO'STRUM. See DIAPHRAGMA.

COPAIBA. See BALSAMUM.

COPAIBA INJE'CTIO. R. Bals. copaibæ ʒ ij. mucilaginis g. Arab. ʒ ss. aquæ calcis ʒ ss. m. proper in gleets, in the latter stage of the gonorrhœa, and in the fluor albus.

COPAIBA CUM OLIBANO MISTU'RA, consists of two drachms of powdered olibanum, mixed with half an ounce of the balsam, with which half an ounce of mucilage of gum arabic, and twice the quantity of honey, are incorporated. Five ounces of cinnamon water are gradually added. In the dose of an ounce, or an ounce and a half, this mixture will be useful in humoral asthmas, in leucorrhœa and gleets.

COPEIA, COPE'LLA AMERICA'NORUM, and COPELGA. The name of a tree in Hispaniola, in America, whose leaf serves for paper, and of which the Spaniards there make cards. This tree affords a bituminous matter resembling pitch. Raii Hist.

CO'PHOS, κωφος, deaf; (from κωφω, to be deaf). A sort of toad mentioned by Nicander. It also signifies deaf, dumb, or both, or a dulness of any of the senses.

COPHOSIS. See COPHOS and DYSCÆA.

CO'POS, (from κοπομαι, to be weary). FATIGUE, WEARINESS.

We are so constituted by nature, that all our exertions must be succeeded by a suitable and proportionate relaxation. We are not calculated for a constant activity; and weariness, without its due share of rest, exhausts the constitution, and shortens life. In our

muscular exertions, we soon find inability succeed extraordinary action; in our mental, languor and a want of comprehension, after a time, come on: and though from habit we gain a power over mind and body, so that the employment of each may be continued for a longer than the usual period, yet we at last yield to weariness, and a sleep so deep as even to resemble death ensues.

Our activity and fatigue must be equally referred to different and opposite states of the nervous power, which we have styled its mobility and torpor. By what means it is exhausted or recruited we know not, but the fact is sufficient for our purpose. Independent of this change, the muscular structure seems to receive some organic injury; since, after great bodily fatigue, rest, though so necessary, is prevented by an obtuse, aching pain. For the effect on the nervous power we know no remedy but sleep; yet coffee and strong tea will often enable us to continue our labours with little present inconvenience. Vinous spirits will sometimes have a similar, but often an opposite effect. Varying the mental action, we have remarked, will prevent weariness. Is, according to the system of Dr. Gall, one portion of the brain only employed in a given occupation; or is a less degree of labour a relief after a greater, as the horse, after a race, is recruited more by walking slowly than by rest? More acute physiologists must decide; but that the fact is true our own experience has taught us. Indeed, there is no more effectual remedy for extraordinary mental fatigue, than that which employs the attention without any great exertion of mind. One reason of this seems to be, that intellectual labour leaves a degree of irritability which will not admit of sleep.

Bodily fatigue does not produce such an irritable state; yet the aching pain, which prevents sleep, requires some remedy. The warm bath is well adapted to relieve this extraordinary tension of the muscular fibres; and opium has a similar effect. Fatigue in a great degree conquers, however, every painful feeling. In the American war, a pilot, in carrying a frigate up Hudson's river, had been, for two or three days and nights, at the helm. They then arrived at a fort, mounting fourteen guns, which it was necessary to silence; the pilot, no longer wanted, sunk on the deck, and slept, during the whole cannonade, with the most perfect tranquillity.

COPO'VICH OCCA'SSOU. A tree mentioned by De Laet, which grows in the West Indies: the leaves resemble those of the pear tree; and the fruit, called *oumery*, is like a large pear, and, when ripe, is eaten as a delicacy. It is not described by the systematic botanists. Raii Hist.

COPRAGO'GUM, (from κοπρος, dung, and αγω, to bring away). The name of a gently purging electuary, mentioned by Rulandus.

COPRIEME'TOS, (from κοπρος, dung, and εμεω, to vomit). A person who vomits feculent matters.

COPROCRI'TICA MEDICAMENTA, (from κοπρος, excrement, and κρινω, to separate). See ECCOPROTICA.

COPROSTA'SIA, (from κοπρος, feces, and ἵσθημι, to remain). A CONSTRICTION of the BELLY.

COPTA'RION, (from κοπή, a small cake). A medicine in the shape of a very small cake, directed for disorders of the aspera arteria and lungs, and for many other intentions, by the ancients.

**CO'PTE.** A small cake, (from *κοπῆ*, to beat or pound; because it was formed by beating or pounding the ingredients into a paste). It was the form of a medicine used by the ancients, generally made of vegetable substances, and applied externally to the stomach, and internally on many occasions.

**CO'PULA**, (quasi *compula*, from *compello*, to restrain). See **LIGAMENTUM**.

**COQUE'NTIA MEDICAME'NTA**, (from *coquo*, to digest). Medicines which promote concoction.

**CO'R.** In chemistry signifies gold; sometimes an intense fire. In botany, it is the heart of vegetables, or their pith. See **MEDITULLIUM** and **CORCULUM**.

**Co'r**, (from *καρ*, contr. *καρ*, Hebrew, *koach*, the middle,) called also by the ancients *cardia*. The **HEART**. This viscus is double, consisting of two cavities on each side, serving for two circulations of the blood, one through every part of the body, and the other through the lungs. The right side of the heart is similar to the left, excepting that both its auricle and ventricle have fewer muscular fibres. The auricle receives blood from the venæ cavæ, and the ventricle throws it into the pulmonary artery.

The situation of the heart is in the middle of and across the cavity of the thorax, but rather inclining to the left; on each side of it lie the lungs, playing on the ribs and diaphragm, and following closely all their motions; attached at their roots to the heart by the pulmonary vessels. The heart is close, on its lower side, to the diaphragm, covered by the pericardium, which is a membranous bag, enclosing this organ and all the parts belonging to it, with a small proportion of fluid or halitus interposed. The figure of the heart is conoid, its base is irregular, because all the large vessels are fixed there. The human heart differs from those of quadrupeds, which are more round: the human rather represents half a cone, because the under part which lies upon the diaphragm is flat.

The apex of the heart is to the left and forwards: its situation varies but little with the motion of the diaphragm, as it lies upon the tendinous part.

The body of the heart is composed of two large muscular cavities, called *ventricles*; one to the right and forwards, the other to the left and backwards. Winslow calls them anterior and posterior.

At the basis of the heart are two muscular bags, called *auricles*, adjoining to the ventricles. They lie contiguous to one another below; but above they are distant, as the aorta and pulmonary artery pass between them. The right is larger than the left, and it is very thin. The left is thicker, unequally square: into which the four pulmonary veins empty themselves. The heart hath a septum divided into two, called *ventricularum*, et *auricularum septum*.

The right auricle receives the two venæ cavæ, one at the upper part, the other at the lower. At their union, these vessels are dilated, forming a sinus, styled *sinus venosus*. The blood, brought there by the contraction of the auricle, passes into the right ventricle, from thence into the pulmonary artery, and through its minutest branches; then through the pulmonary veins, into the left auricle, which propels it into the left ventricle, from whence it is sent into the aorta, to be dispersed all over the body, and at last is returned by the two cavæ to the right auricle.

The two cavæ go into the middle part of the auricle, each a little inclined inwards; the angle between them is partly filled up by the left auricle; there is a transverse ridge upon the septum auricularum, called *tuberculum Loweri*, which is placed there to hinder the current of the blood from each cava rushing directly against each other. The existence of any such tubercle is, however, denied by later authors; and, indeed, it could be of little utility, since the opposing currents of blood would supply its office.

The right auricle hath an appendage, which serves to fill up the part between that and the aorta; for the same reason the left hath a similar appendage upwards, and to the left side, to fill up the space between the pulmonary artery and the left ventricle. The whole of the cavity of the auricles internally is not smooth, but composed of fasciculi, running from one side to the other. This fasciculated texture is less in the left than in the right auricle, and is most observable in the appendages of the auricles; supposed to be with a view to hinder the blood from concreting, as there it is most out of the way of the circulation; but with little reason, as solid bodies assist concretion. It is probably designed to assist the weaker action of the auricle at a distance from the centre of its greatest power.

Under the reputed *tuberculum Loweri*, we see the foramen ovale, which runs upwards from the right to the left auricle, and goes through the auricularum septum, directly opposed to the vena cava inferior. Soon after the child is born this hole closes, though in some instances it remains a little open, even in old age. In the fœtus there is a valve which is loose, but this valve in adults is connected to the septum.

The *coronary vein* opens into the right auricle, between the orifice of the cava inferior and the passage into the ventricle. The fibres of the auricle are so irregularly disposed as to act as sphincters, and hinder the regurgitation of the blood.

At the insertion of the cava inferior, is a valve called *valvula nobilis*: it is larger in the fœtus than in the adult; and its office is to hinder the blood from flowing back into the vein.

The right ventricle, on its lower part, lies on the diaphragm; and on its upper, makes the larger part of the heart. It is thicker than the auricle, and the whole internal surface of it is fasciculated. Its lower orifice receives the blood, and the upper yields it a passage: the auricular orifice is surrounded by a loose membrane, which hangs into the ventricle, connected with it by loose tendinous chords. When, therefore, the blood flows into the ventricle, this membrane hangs loose; but, on the blood regurgitating, the fluid behind presses it backward, and produces the effect of a valve. These tendinous chords are divided into three sets, and hence called *valvulæ tricuspidales*.

The other orifice, which leads into the pulmonary artery just at its beginning, is furnished with three semilunar valves, whose loose floating edges lie towards the artery, whilst the others are fixed to the ventricle. In order to make these valves close more accurately, each hath a little mamilla in its middle, (to fill up the triangular space which is left,) called the *corpus sesamoides*: these valves hinder the blood from regurgitating into the heart.

The left auricle lies rather on the back part, behind

the basis of the heart, and towards the left. It is situated below the bifurcation of the trachea and pulmonary artery. It is stronger than the other, and is smooth internally, except at the little appendicle. There are no valves on the orifices of the pulmonary veins. This auricle is stronger than the right, because the left ventricle is stronger than the right, and therefore requires more force to overcome the resistance.

The left ventricle is fasciculated. At the orifice, between the auricle and the ventricle, is a valve, called the *valvula mitralis* vel *episcopalis*, so called from resembling a mitre, which runs from the one to the other; it is fissured into two points, which are fixed to the auricles, and hang down loose into the ventricles, resembling in structure the *valvula tricuspidales*. The *chordæ tendineæ*, and *columnæ carneæ*, are the same as in the other, but much stronger. The orifice, by which it expels the blood, is situated in the middle of the ventricle; so the aorta rises from the middle of the basis of the heart. The larger flap of the *valvula mitralis* hangs down between the auricle and ventricle: and it has been supposed to serve as a valve to both the auricular and arterial orifices; but for this purpose neither its structure nor its situation is adapted.

The coronary arteries are two. See *CORONARIÆ ARTERIÆ*.

The *foramina thebesii* are venal orifices, said to open into all the cavities of the heart.

The fibres of the heart are muscular; at each of the orifices is a tendinous ring, where the fibres of the ventricles begin, which go downwards to the apex, where they turn in, and run up on the inside, representing in perspective a figure of 8. There are some fibres common to both ventricles, which, as they compress them both, Dr. Hunter thinks is a proof of their acting at the same time.

According to Lancisi, the nerves of the heart are both numerous and large. In each side there are inserted five pair; viz. from the par vagum, the superior intercostal pair, the vertebral pair, the inferior intercostal pair, and the phrenic pair. The heart hath two motions, systole and diastole. Harvey and others say, that the systoles of the two auricles of the heart, the two ventricles, and the aorta and pulmonary artery, are respectively synchronous with each other: but Dr. Nichols thinks that the motion of the auricles is synchronous, and that the ventricles and arteries are likewise dilated and contracted at different periods of time. As the auricles throw blood into their respective ventricles, so do the ventricles perform the same duty; viz. the right throws blood into the pulmonary artery, the left into the aorta.

The real course of the circulation, and the alternate action of the different parts of the heart, we shall describe. The blood passing from the left ventricle into the aorta, is returned by the *venæ cavæ*. It then passes into the right auricle. This sac is excited to contraction by the dilatation, and propels the blood into the right ventricle. Their action is consequently successive. For a similar reason, the action of the left auricle and ventricles is successive; but as the times required for emptying and filling are nearly equal, the action of the auricles and ventricles are respectively synchronous. This succession is proved by actual observation of the action of the heart in the mammalia, and from the si-

tuation of the different valves. Animals without lungs, and which do not breathe, have only a single heart; but a considerable artery from the aorta passes to the organs which supply the place of lungs, as the gills of fish, and bring back the blood meliorated by the action of air.

See Winslow's Anatomy. Haller's Physiology. Senac on the Heart.

*CORACINE*, (from *κοραξ*, *corvus*, a crow; so named from its black colour). An epithet for a lozenge, quoted by Galen from Asclepiades.

*CORACINI LAPIDES*, (from the same). Certain bones found in the head of the *coracinus*, the crow fish, found in the Nile, and other rivers of the Mediterranean sea.

*CORACOBOTANE*, (from *κοραξ*, a crow, and *βοτάνη*, a plant; from the dark colour of its bark). See *LAURUS ALEXANDRINA*.

*CORACO-BRACHIÆ'US* (*MUSCULUS*), (from *κοραξ*, a crow, and *brachium*, an arm,) *coracoides*, and *coracoideus*. It rises from the point of the coracoid process, and is inserted internally into the middle of the os humeri. Riolan gives it this name, and Arantius first took notice of it as belonging to the arm. Winslow calls it *coraco-brachialis*. It hath been called *perforatus Casserii*, because this author first gave a particular description of it, and because it is perforated in the middle, to give passage to a nerve. Spigelius calls it *nonus humeri flaccitini*.

*CORACO-HYOIDÆ'US*, called also *omo-hyoidæus*, *omo-plato-hyoidæus*, and *costo-hyoidæus*. It rises from the superior part of the upper costa of the scapula, and is inserted into the basis of the os hyoides, to pull it downwards and backwards.

*CORACOIDES PROCE'SSUS*, (from its likeness to a crow's beak—*κοραξ*, and *εἶδος*,) *sigmoides processus*. The BEAK-LIKE PROCESS. It projects from the anterior extremity of the upper costa of the SCAPULA, q. v. and is a little crooked, with its point inclining forwards: a ligament passes from its superior part, to connect it to the acromion and clavicle. At the birth it is cartilaginous, and called *anchoralis processus*; *anchyroides*, *cornicularis*, *conchyroides*, *processus*.

*CORACOIDES MUSCULUS*. See *CORACO-BRACHIÆUS*. It is called *coracoides*, because it proceeds from the process which is formed like a crow's beak.

*CORACOIDÆUS*. See *CORACO-BRACHIÆUS*.

*CORA'CUM EMPLA'STRUM*. The name of a plaster described by P. Ægineta.

*CORALLI'NA*, (a dim. of *corallium*, coral,) *musculus marinus*, *corallina anglica*, *corallina alba*, SEA CORALLINE, and WHITE WORMSEED.

It is a marine production, common on rocks and shells in shallow water. It resembles a small plant without leaves, consisting of several jointed branches, generally of a greyish colour, sometimes greenish, yellowish, or reddish; of a brittle stony substance, friable betwixt the fingers, and crackling between the teeth. It hath commonly been supposed a vegetable; but is really of animal origin, and the habitation of an animal belonging to the class of *polypti*. The corallines formerly were a very extensive groupe, including the *tubulariæ sertulariæ*, the *alcyones*, sponges, &c.; but we are indebted to Ellis for more correct ideas, and more accurate distinctions. For the *corallina officinalis*, see Ellis, Pl. 24, Fig. A. Its height is about two or three inches.

It ought to be entire, of a strong sea smell and salt taste. Worms will live in a strong infusion of it for several days, notwithstanding it has been styled an anthelmintic. By calcination in a strong fire, it becomes true quicklime, and consequently resembles other testaceous marine bodies. See Neumann's Chem. Works, Lewis's Mat. Med. Cullen's Mat. Med.

CORALLI'NA HELMINTHO CORTON, a species of conserva, found chiefly in Corsica, and employed as an anthelmintic.

CORA'LLIUM, (from *κορη*, a daughter, and *ἄλος*, of the sea.) CORAL. It is also called *lithodendron*, or TREE STONE; *almarago*, *mergen*, *almargen*, *gorgonias*.

CORA'LLIUM ALBUM RAMOSUM, *Madrepora vulgaris*, *corallium*, *officinarium oculatum*, and WHITE CORAL.

CORA'LLIUM NIGRUM. Also called *antiphates*, *lithophyton nigrum*, *pseudocorallium nigrum*, and BLACK CORAL.

What is usually shown for black coral is petrified wood. See KERATOPHYTON.

The best sort of white coral is brought from the Mediterranean, and, like the other corals, solid.

CORA'LLIUM RUBRUM. RED CORAL, called also *acmæ azur*.

The most ancient naturalists considered coral as a vegetating stone; Dioscorides, Pliny, Cæsalpinus, and Tournefort, a plant, which indeed it greatly resembles. It is, however, the work and habitation of a polypus, and its internal parts resemble marble in hardness: the external covering is soft, and the extremity is still softer. It hardens by age, but not, as supposed, by the access of air. The surface is mamillated, and each mamilla is the residence of an animal. By calcination it is found to consist of many concentric laminæ.

The red coral has been chiefly used in medicine. It is, like the others, a hard, brittle, branched substance, resembling a plant without leaves, usually about the thickness of a goose quill, full of knots, sometimes straight, and sometimes variously bent, both externally and internally of a deep bright red colour. It is found adhering to rocks and other bodies, particularly in the Indian and Mediterranean seas, and in the Persian Gulf. The soft fungous matter which covers it contains a great number of cells full of a milky liquor. This cortical part is separated easily whilst fresh and soft.

Red coral contains some iron; its basis seems to be the same as that of coralline and other animal earths. It is alkaline and absorbent.

The common testacea, coloured with dragon's blood, are sold for it; but by shaking this substitute in water, the fraud is discovered; for the colouring matter being separated, the other becomes white, whilst red coral is still red. The fraud is, however, innocent, and, indeed, the substituted earth is often a more active medicine; but the coral and its substitutes are equally neglected. It was once considered as an absorbent, an astringent, a tonic, and a diuretic. It is now only, and indeed very seldom, the basis of a tooth powder.

Oil of aniseeds, white wax, milk, or juice of citrons, equally extract the red colour from coral.

CORALLODE'NDRON, (from *κοραλλιον*, coral, and *δενδρον*, a tree; resembling in hardness and colour a piece of coral). The leaves for the most part consist of three lobes; the flowers are papilionaceous, and suc-

ceeded by knobbed bivalve pods, which contain several kidney shaped seeds. A confection made with the flowers is called *caryl*.

*Arbor coral siliqua sylvestris spinosa*, THREE LEAVED AMERICAN CORAL TREE, with deep red flowers, commonly called, in America, the BEAN TREE. *Erythrina corallodendron* Lin. Sp. Pl. 992. var. *α*.

*Arbor coral. min.* or the LESSER THREE LEAVED AMERICAN CORAL TREE, with black seeds and spines.

Ray informs us, that the inhabitants of Malabar make sheaths for their knives and swords with the wood; that they use the wood with the bark which they call *sarassas*, for washing their garments; and of the flower they make the confection called *caryl*. The powdered leaves, when boiled with the mature cacao nut, consume venereal buboes, and ease pains in the bones. The juice of the leaves, taken with the oil *sergetim*, mitigates venereal blindness.

CORALLOI'DES, (from *κοραλλιον*, coral, and *ειδος*, likeness). See DENTARIA and CORALLODENDRON.

CORALLOI'DES FUNGUS, (from *κοραλλιον*, coral, and *ειδος*, likeness,) also called *erotylus*. *Clavaria coralloides* Lin. Sp. Pl. 1652. It is of a fleshy, fungous texture, of a yellow colour, and branched in the manner of coral. It is said to be corroborant and astringent, but little notice is now taken of it.

CO'RCHORON, (from *κορη*, the pupil of the eye, and *κορεω*, to purge). See ANAGALLIS.

CO'RCULUM, (a dim. of *cor*, the heart); called also *cor*. The heart or essence of a seed, and the primordium of the future plant attached to and involved in the cotyledon. It consists of the *plumula*, the ascending scaly part, and the *rostellum*, the descending part of the corculum.

CORD. EUR. An abbreviation of Euricii Cordii Botanologicon, sive Colloquium de Herbis.

CORD. An abbreviation of Valerii Cordi Historia Stirpium.

CO'RNA, or CHO'RNA. See CHORDEE.

CO'RNA TY'MPANI. The portio dura of the seventh pair of nerves having entered the tympanum, sends a small branch to the stapes, and another more considerable one, which runs across the tympanum from behind forwards, passes between the long leg of the incus and the handle of the malleus, then goes out at the same place where the tendon of the anterior muscle of the malleus enters. It is called *chorda tympani*, because it crosses the tympanum as a cord crosses the bottom of a drum.

Dr. Monro thinks that the *chorda tympani* is formed by the second branch of the fifth pair, as well as by the portio dura of the seventh.

CO'RDÆ WILLI'SII. See DURA MATER.

CO'RDIA SEBESTI'NA. See SEBESTEN.

CORDIA'LA. See CARDIACA.

CORDO'LIUM, (from *cor*, the heart, and *dolor*, pain). See CARDIALGIA.

CO'RE. (Greek.) See PUPILLA OCULI.

CORE'MATA, (from *κορεω*, to cleanse). BRUSHES; but in P. Ægineta it is used to signify medicines for cleaning the skin.

CORIA'CEUS, (from *corium*, leather). In botany it means thick and tough, like leather.

CORIA'NDRUM. CORIANDER. (Derived, perhaps, from *κορις*, *cimex*, a bug, because the green herb

and seed stink intolerably); also called *cassibor* and *corianon*. The *coriandrum sativum* Lin. Sp. Pl. 367. The plant is an umbelliferous one, with finely divided leaves; the lower ones like parsley; the seeds of a pale yellowish-brown colour, and striated. It is a native of Italy; cultivated in some parts of England; annual, flowers in June, and ripens in July or August.

The leaves have a small degree of an aromatic smell, mixed with somewhat offensive. The seeds when fresh are also disagreeable, but by drying they become grateful: to the taste they are moderately warm and pungent. Dioscorides has asserted, that these seeds, taken in a considerable quantity, produce deleterious effects; but Dr. Withering has known six drachms of the seeds taken at once without any remarkable consequences. Mathiolus considers them as antiseptic; but they are generally used as stomachic and carminative. Mixed with sena in infusion, they more powerfully correct its odour and taste than any other aromatic, and are equally powerful in obviating the colic pain it is very apt to produce. Rectified spirit of wine takes up all their virtue, but water only partially extracts it. Distilled with water, a small quantity of essential oil is obtained, which partakes agreeably of the quality of the seeds. Pure spirit carries off, in evaporation, a great part of their flavour. Raii Hist. and Lewis's and Cullen's Mat. Med.

CORIA'NON. See CORIANDRUM.

CORIA'RUM, (from *corium*, leather; because the dried leaves are used in tanning). See RHUS.

CO'RIS, (from *κείρω*, to cleave, or cut; so called because it heals wounds). See SYMPHYTUM PETRÆUM.

CO'RIS LUTE'A, CO'RIS LEGITIMA CRE'TICA. See HYPERICUM SAXATILE.

CO'RIS MONSPELIENSIS Lin. Sp. Pl. 252. A biennial plant of the south of Europe, intensely bitter and nauseous, but apparently an active medicine; and employed, it is said, with success in syphilis.

CO'RUM, (from the Hebrew term *gor*). The skin of a beast; also LEATHER, from whence the buff appearance upon the blood is called *coriaceous*. See DARTOS.

CORK, the bark of the *quercus suber* Lin. Sp. Pl. 1413; formerly employed as an astringent, but now disused. It affords an acid; for which see CHEMISTRY.

CORN. See CEREALIA.

CORN SALAD, an early salad possessing the celebrated antiscorbutic qualities of early vegetables. It is the *valeriana locusta* Lin. Sp. Pl. 47, var. *α*.

CORNACHI'NI PU'LVIS. See SCAMMONIUM.

CO'RNEA, (from *cornu*, as it resembles horn). A COAT of the EYE, which is also called *sclerotica ceratoides*. It is the first proper coat of the eye, strong, thick, and tendinous; its anterior part is distinguished by the name of *cornea transparenens*, or *lucida*, and the posterior part by that of *cornea opaca*. The transparent part is sometimes called *cornea*; and the posterior part *cornea opaca*, and *sclerotica*, or *sclerotis*: the former only is elastic. The opaque part is made up of several laminae closely connected, whose fibres run in different directions, and form a dense, compact substance.

The cornea consists of an external and internal lamina, each of which is composed of thinner laminae. Its substance is in some degree elastic, to fit the eye to different magnitudes and distances; it is also perfo-

rated with many small holes, through which a fluid is supposed to be constantly discharged, but which soon evaporates.

The sclerotica and cornea are furnished with arteries, chiefly from a branch of the internal carotid. The nerves proceed principally from the ophthalmic branch of the fifth pair.

The cornea transmits the rays of light into the eye, and produces the first refraction of the rays necessary to vision. Its natural transparency is liable to be obscured by inflammation, by abscesses, and ulcers.

It seems more proper to consider this coat of the eye as the sclerotica, and the cornea only as its transparent part. See SCLEROTICA.

CORNE'STA. See CORNUMUSA.

CORNI'CULA, (from *cornu*, horn). A conical perforated instrument of horn, which was formerly used as a cupping glass. The broad part was applied to the skin, and by sucking from the smaller end, the skin was raised in the instrument.

CORNICULA'TÆ PROCE'SSUS. See CORACOIDES PROCESSUS.

CORNICULA'TÆ PLA'NTÆ, (from *cornu*, horn). Plants which produce many distinct horned seed pods, called *siliquæ*.

CO'RNU ARIETIS, the appearance of the section of the pes hippocampi, a portion of the brain.

CO'RNU CE'RVI, (from the Chaldee term *karnah*,) in chemistry, is the beak of an alembic; but it generally means the HORN of the STAG or HART, particularly of the male red deer, though the horns of the fallow deer are commonly employed. See DAMA.

Hart's horn shaved gives out to water, by boiling, a soft insipid and flavourless jelly, in quantity about one-fourth of the weight of the horn. This jelly is used as a nourishing diet, and to obtund acrimony; it is usually mixed with the juice of lemons, or with wine or spice, according to the different circumstances of the patient. The Edinburgh college directs the following:

*Jelly of hart's horn.* Boil half a pound of the shavings of hart's horn, in six pints of water, to a quart: to the strained liquor add one ounce of the juice of lemon, or of Seville orange, four ounces of mountain wine, and half a pound of sugar; then boil the whole to a proper consistence.

The horns of deer are used for obtaining a liquor, salt, and oil, denominated liquor, sal, and oleum cornu cervi; but there is no observable difference betwixt one animal substance and another for this purpose, except in the different proportion of oil which they afford; hence the bones of oxen and other animals, the hoofs of horses, the horns of oxen, ivory, the shells of tortoises, hair, and silk, all afford nearly the same liquor, salt, and oil. See ALCALI.

Hart's horn is said by former chemists to be prepared philosophically, when it is suspended in a still, while distilling any spirituous liquor; the horn being cut into thin slices, and exposed to the vapours, by which it is rendered white and friable. This preparation was accidentally discovered at Dresden, in Saxony, by Casper Pantzerus, an apothecary and native of Prussia. At present it is boiled till the black part separates, and then the inner white part is dried for use. Hoffman orders some alkaline salt to be put in the water when boiling,

to soften the black part. This process frees the horns from their glutinous matter, and thus renders them friable.

By calcination, the earthy part is obtained most pure and perfect; its quantity about half the weight of the horn. The London college directs pieces of hart's horn to be burnt till they become perfectly white, then rubbed to a very fine powder, called *cornu cervi calcinatum*, calcined hart's horn, phosphas calcis of the last edition of the Edinburgh Pharmacopœia, which is to be powdered and levigated for use. As the intention of this operation is to separate the volatile parts, the heat cannot be too great: yet some caution is necessary in this respect, as by suddenly hardening the external parts, the internal are guarded from the action of fire; for the earth of hart's horn is not convertible into quick lime. The horns left after distilling the spirit, salt, and oil, are as proper as fresh ones; but they are a mixture of calcareous earth and phosphoric acid, and the weakest of the absorbents. The earth of all bones is similar. Hart's horn, by late experiments, is found to contain 27 parts of gelatine, 57.5 of phosphat of lime, and one of carbonate of lime, with about 14.5 of water. The bones of animals, sometimes substituted, contain also a small proportion of phosphat of magnesia. Burnt hart's horn, or burnt bones, are therefore slightly contaminated with these salts. The phosphat of lime has been recommended in rickets by M. Bonhomme, and used in France, it is said, with success; but it has seldom been given in England.

Solutions of this earth in vegetable acids are supposed to be restringent, and they probably act only by uniting with acid humours in the primæ viæ. The London college only directs the following decoction of hart's horn.

Take of burnt hart's horn prepared, two ounces; gum arabic, six drachms; distilled water, three pints; boil the water to a quart, and strain it. This is used as a common drink in fevers attended with laxity of the bowels, or after violent diarrhœas.

*Decoctum cretaceum.* Take of chalk finely powdered, two ounces; of gum arabic, half an ounce; boil it in three pints to two of water; pour off the liquor from the heavier parts that fall to the bottom. This may be substituted for the former, but each would be useless if the gum was not an ingredient.

If a little cochineal is added, it is called *decoctum rubrum*, red decoction. See Lewis's *Materia Medica*. Neumann's *Chemical Works*.

CO'RNA UNICO'RNA. See UNICORNU.

CO'RNA FO'SSILE. See UNICORNU.

CO'RNA CERVI'NUM. See CORONOPUS.

CORNU'A, (from *cornu*, horn). Horny excrescences, which sometimes arise on some part of the body.

CORNU'A UTE'RI, called also *flectenæ*. In comparative anatomy, the horns of the womb. The womb in some quadrupeds is triangular, and its angles resemble horns.

CORNUMU'SA. A RETORT, called also *batia*, *cornesta*, *cornuta*.

CO'RNUS. The CORNELL TREE. *Cornus sanguinea* Lin. Sp. Pl. 171. The fruit is moderately cooling and astringent. The *schagri cottam* is a species of cornel which grows in Malabar, the expressed juice of which, drunk with sugar, is cooling and astringent.

CORNU'TA, (from *cornu*; from its resemblance to a horn). A RETORT. See CORNUMUSA.

CORO'CRUM. See FERMENTUM.

CORO'LLA, (from *corona*, a crown). One of the seven parts of fructification, according to Linnæus, who defines it the inner bark of the plant present in the flower: it is the coloured or painted leaves of the plant, consisting of petals, and nectarium. The corolla of Linnæus, English botanists call blossom.

CORO'NA, (from the Hebrew term *koren*). A CROWN. In botany it is a series of small beards, or rays, in discoid flowers.

CORO'NA SE'MINIS is the appendage to the top of many seeds, enabling them to disperse, serving them as wings. This is either the *calyculus*, formed of the perianthium of the flower, as in the scabiosa, knautica, &c.; or the pappus (down), as in the hieracium, sonchus, &c.

CORO'NA CILIA'RI. See CILIARE LIGAMENTUM.

CORO'NA IMPERIA'LI. CROWN IMPERIAL.

It is a bell-shaped flower, and an ornament of our gardens. In the petals is a sweet juice, which the Turks use as an emetic; but the whole plant is esteemed poisonous.

CORO'NA RE'GIA. See MELILOTUS.

CORO'NA SO'LI. SUN FLOWER; called also *chimalati*; *helianthus annuus* Lin. Sp. Pl. 1276. This flower, well known as an ornament in gardens, is a native of Peru, and other warm countries of America. It is not known to possess any valuable medicinal qualities; though it is noticed as heating, and an agreeable food. It produces a resinous tear, which is its most active part. A gum also flows from it, if the seed vessels when ripe are cut small, and boiled in water. The seeds are made into bread.

CORO'NA SO'LI PA'RVO FLO'RE TUBERO'SA RADICE. See BATTATAS CANADENSIS.

CORO'NA TE'RRÆ. See HEDERA TERRESTRIS.

CORO'NA GLANDIS, the margin of glans penis, just above the odoriferous glands.

CORO'NA VENERIS, the eruptions which surround the forehead at the roots of the hair, in cases of syphilis.

CORONA'LE OS, (from *corona*, a crown). See OS FRONTIS.

CORONA'LI, (from the same,) vel ARCUA'LI SUTU'RA, (from *arcus*, a bow). The suture upon the crown of the head.

CORONA'RIA LIGAME'NTA, (from *corona*, a crown). The CORONARY LIGAMENT of the radius is a sort of ligamentary hoop, surrounding the circular circumference of the head of that bone, reaching from one side of the small lateral sigmoid, or transverse cavity of the ulna, to the other, in an arch, which is about three-fourths of a circle. It is nearly as solid as a cartilage. It connects the radius very closely to the ulna, yet admits of the pronation and the supination of the arm.

CORONA'RIÆ ARTE'RIÆ et VENÆ, (from the same). The CORONARY ARTERIES and VEINS. Those of the heart are also called *cardiacæ*. The first branches which the aorta sends off are the coronary arteries of the heart; and they appear between the aorta and the pulmonary artery, running round the basis of the heart and to the apex, giving branches chiefly to their respective ventricles. They frequently anastomose both at the basis and apex. One of these runs an-

teriorly, the other posteriorly on the heart, and sometimes there are three. They are lost in the substance of the muscle.

The coronary veins of the heart follow very nearly the arteries; they rise chiefly from the right auricle, and come out in the angle between the vena cava and the passage into the ventricle; one principal branch runs to the apex; the great trunk, to the other parts. Dr. Hunter says, that the coronary vein of the heart opens into the right auricle, between the orifice of the cava inferior and the passage into the ventricle, and is furnished with a semilunar valve, to hinder the blood from flowing back.

The great coronary vein, and the orifice by which it communicates with the right sinus of the heart, were known, it has been said by M. Wolf, to Galen; but Eustachius seems to have been the first who noticed the valve with which this orifice is furnished. Since his time, M. Wolf says anatomical writers have constantly spoken of this valve as of a semilunar shape; but he asserts that its figure is oblong and narrow, and that it is a peculiar valve, different from every other in the human body.

The coronary artery of the stomach rises from the cœliaca, goes first to the left side of that organ, a little beyond the superior orifice, round which it throws branches, and also to every part of the stomach near it: and these branches communicate with those which run along the bottom of the stomach to the pylorus: afterwards it runs on the right side of the superior orifice, along the small curvature of the stomach, almost to the pylorus, where it communicates with the arteria pylorica, and turning towards the small lobe of the liver, it gives off some branches to it: then it advances under the ductus venosus to the left lobe of the liver, in which it is lost near the beginning of the duct just named, having first given off some small branches to the neighbouring parts of the diaphragm and omentum.

The coronary vein of the stomach is sometimes a branch from the vena portæ ventralis, or from its principal branches. It sometimes springs from the splenica. The *coronaria ventriculi* is so called, because it surrounds its upper orifice. It runs along the small arch to the pylorus, and gives out branches to the sides of the stomach.

**CORONA'RIVM LIGAME'NTVM**, (from the same). See JECUR.

**CORONA'RIVS STOMA'CHICVS**. The ramification of the nerves from the eighth pair near the upper orifice of the stomach.

**CORONA'TVS**, (from *corona*, a crown). In botany it means crowned, appearing like a coronet.

**CORO'NE**, (Greek). A crow. The acute process of the lower jaw bone is so called from its likeness to a crow's beak. See also PROCESSVS.

**CORONILLA I'NDICA**, (a dim. of *corona*; from the appearance of its flower). See INDICVM.

**CORONILLA MONTA'NA**. See EMERVS MINOR.

**CORO'NOID**, (from *κορωνη*, a crow, and *ειδος*, likeness; resembling a crow's beak). See PROCESSVS.

**CORONOIDES APO'PHYSIS U'LNÆ**. It is at the upper end of the *ulna* prominent, and a little pointed, resembling a broad short beak. It is received into the anterior cavity above the pulley, at the lower extremity of the *os humeri*, when the fore arm is bent.

**CORONOIDES APO'PHYSIS MAXI'LLÆ**. See MAXILLA INFERIOR.

**CORONO'PUS**, (from *κορωνη*, a carrion crow, and *πους*, foot, the plant being said to resemble a crow's foot,) *cornu cervinum*, *stella terræ*, *plantago*, BUCK'S HORN PLANTAIN. *Plantago coronopus* Lin. Sp. Pl. 166.

Its leaves are deeply cut; its root long and slender; many of its leaves lie flat on the earth in a circular manner, whence the name *stella terræ*. The leaves are downy, long, and narrow; the stalk hoary; the seeds small, and of a dark brown colour. It grows on sandy places and heaths, and flowers in June.

Its medical virtues are the same as those of the other plantains. See PLANTAGO.

**CO'RPORA ALBICA'NTIA**, (from *corpus*, a body). See CEREBRUM.

**CO'RPORA CAVERNO'SA PE'NIS**, called also *nerveæ spongiosa*. The two bodies, thus named, rise by two distinct crura from the lower part of the ossa pubis; after which they join, and are continued to the glans. They are separated by a septum, disposed like the teeth of a comb, so that any fluid forced into one distends the other. The two crura are connected to the symphysis of the os pubis by the ligamentum suspensorium, which proceeds from the cartilage, and is diffused upon the sheaths of the corpora cavernosa. Towards the upper extremity of the corpora cavernosa are several white ligaments, which seem to be placed there to hinder the penis from being too much distended. In the axis between each corpus cavernosum an artery and a vein run, which enter near the union of the crura, and ramify throughout the spongy substance.

**CO'RPORA FIMBRIA'TA**. A border on the edge of the fornix in the brain. See FORNIX.

**CO'RPORA LOBO'SA**. See RENES.

**CO'RPORA OLIVA'RIA**. Two eminences on the medulla oblongata.

**CO'RPORA PYRAMIDA'LIA**. Two other eminences on the medulla oblongata, near the corpora olivaria, confounded by Willis with the latter.

**CO'RPORA STRIA'TA**. Two prominences in the lateral ventricles of the brain, in which we meet with a great number of white and ash coloured lines alternately disposed, but these are only the transverse section of the medullary and cortical laminæ mixed together. See CEREBRUM.

**CORPULE'NTIA**, (from *corpus*, a body). See OBESITAS and POLYSARCIA.

**CO'RPIVS CALLO'SVM**, called also *Callus*. If the falx is cut away from the crista galli, turned backwards, and the two lateral parts of the cerebrum gently separated, we see a longitudinal portion of a white convex body, named *corpus callosum*, which is the middle portion of the medullary substance of the brain: under the inferior sinus of the falx, and also a little towards each side, it is parted from the mass of the cerebrum, to which it is simply contiguous from one end of that sinus to the other; so that at this place the edge of the inside of this hemisphere only lies on the corpus callosum, much in the same manner as the anterior and posterior lobes lie on the dura mater. Both extremities of this medullary body terminate by a small edge bent transversely downwards. The surface of the corpus callosum is covered by the pia mater; along the middle

of its surface, from one end to the other, there is a kind of raphe, or seam, which hath on each side a white chord. The corpus callosum covers the two lateral ventricles. See CEREBRUM.

Co'Rpus GLANDULO'SUM. See PRŌSTATĒ.

Co'Rpus LUTEUM. A yellow substance; sometimes, in the early period, a cavity found in the ovarium after impregnation. When there are twins, one is found in each, but scarcely ever two in the same ovarium. They continue some months, and are supposed to be the part from which the ovum has been separated. While the surrounding parts are filled by injection, a cavity is observed in the centre of this body.

Co'Rpus MUCO'SUM. See RETE MUCOSUM.

Co'Rpus PAMPINIFO'RME, PYRAMIDA'LE. The SPERMATIC CHORD. See SPERMATICA CHORDA.

Co'Rpus RETICULA'RE. See RETE MUCOSUM.

Co'Rpus SESAMOIDE'UM. See COR.

Co'Rpus SPONGIO'SUM URE'THRE. The SPONGY BODY OF THE URETHRA. It is of the same substance as the corpora cavernosa, and surrounds the urethra. That part which is next the prostate is thick, and styled the bulb of the urethra; but as it runs on, it becomes smaller, and at the extremity forms the gland.

Co'Rpus VARICO'SUM. See SPERMATICA CHORDA.

CORRA'GO, (from *cor*, the heart; it being supposed to have a good effect in comforting the heart). See BORRAGO.

CO'RRE, (from *κείρω*, to shave). See TEMPORA.

CORRE'CTIO, (from *corrigo*, to correct). CORRECTION. This word, in pharmacy, signifies additions which correct the noxious quality, the violent operation, or the taste, of medicines.

CORRIGIO'LA, (from *corrigia*, a point or knot). KNOT GRASS. See GRAMEN POLYGONUM.

CORROBORA'NTIA, (from *corroboro*, to strengthen,) all such medicines as are suited to strengthen the body, and therefore to restore the strength which has been lost. Dr. Cullen thinks, as a general term, it is improper; still as it is employed for medicines which increase the tone of the moving fibres, it may be allowable. Tonics and astringents are, however, the only medicines of this class; for though nutritious substances may be supposed to give strength, yet adding to the quantity of fluids without at the same time increasing the strength of the containing vessels, is a frequent cause of languor and debility. (See on this subject *Conspectus Medicinæ Theoreticæ Doctoris Gregory de Remediis Roborantibus*). Under this head are placed absorbents, agglutinants, and astringents. These give bulk and firmness to the solids, which are rendered necessary by the continual waste which the actions of life occasion. Absorbents remove redundant moisture, astringents contract the relaxed fibres, and agglutinants add substance, where a previous waste renders a supply necessary.

CORRODE'NTIA, (from *corrodo*, to eat away). Corrosive or corroding medicines, also called *cathartica*. They are divided into, 1st, The MILD, such as burnt alum, the ashes of green wood, calomel, calx hydrargyri alba, and zincum vitriolatum purificatum; 2d, The STRONG, as hydrargyrus nitratus ruber, colcothar vitrioli, trochisci de minio Vigonis; 3d, The STRONGEST, as butyrum antimonii, lapis infernalis, hydrargyrus muriatus, aqua kali, et acidum vitriolicum. Corrosives generally

destroy the life of the part to which they are applied, either by their stimulus exhausting the excitability, or, in some instances, by their affinity for moisture. After this destruction of life they differ by acting chemically on the dead matter, and destroying it. Of the corrosives which destroy life, without acting on the dead matter, are the savine, the euphorbium, the gall nut powder, sugar, and the cevadilla (the Indian caustic barley). Every active stimulant produces in different degrees the same effects. Those which seem to destroy and decompose a part by their affinity for moisture, are the alkalis, lime, and perhaps barytes. These belong, also, to the second class, viz. corrosives, which act on the dead animal matter. Among them we may enumerate the argentum nitratum (lunar caustic,) butter of antimony, blue vitriol, corrosive sublimate, calomel, verdigris, red precipitate, burnt alum, and the mineral acids. These are all oxygenated preparations, and probably destroy life by their excess of stimulus.

CORRO'SIO, (from *corrodo*, to eat away). CORROSION. It is the action of appropriate menstrua on bodies, so as to produce new combinations and a change of their form without converting them to fluids. This depends on the same principles as solution. The subjects are usually metals; and the modes are either, first, by immersing the body to be corroded in a fluid menstruum, which is called corrosion by immersion; or secondly, by exposing it to the action of some vapour, and this is called cementation. There are other kinds of corrosion; as sprinkling the subject with some appropriate fluid, and afterwards rubbing it with some dry substance.

CORRUGA'TOR COITERII, (from *corrugo*, to wrinkle). Volcherus Coiter first took notice of these muscles. The corrugator arises fleshy from the internal angular process of the os frontis, above the joining of the os nasi, and the nasal process of the maxillary bone; from thence it runs outwards, and a little upwards. It is inserted into the inner and inferior fleshy part of the occipito-frontalis muscle, where it joins with the orbicularis palpebrarum, and extends outwards as far as the middle of the superciliary ridge. When one of these muscles acts, it draws the eye brow of that side towards the other; and makes it project over the inner canthus of the eye: when both act, they pull down the skin of the forehead, and make it wrinkle, particularly between the eye brows. This muscle is called by Winslow *musculus supercilii*; by Douglas, *frontalis verus musculus*; and by Riolan, *carnosa musculosa membrana*.

CORSĒ. See TEMPORA.

CORSO'DES, (from *κορση*, a tuft of hair, and *ειδος*, likeness; from its resemblance to hair). See AMIANTHUS.

CO'RTALON. See ERIGERUM.

CO'RTEX, (from *corium*, the skin, and *tego*, to cover; as covering the inner rind of the tree). The bark or outward rind of vegetables. It is the name of many drugs consisting of the barks of trees or roots, viz.

Co'RTEX ANGELINĒ. The tree is unknown. It is found in the island of Grenada, and employed as an anthelmintic: an ounce of the bark is boiled in three pints of water to one, and two or three table spoonfuls are given every morning.

Co'RTEX ANGUSTURĒ. See ANGUSTURA.

Co'RTEX BELLA-AYE. The bark of a tree found in

the island of Madagascar. From its sensible qualities, it appears to be a powerful astringent; and it is employed in hæmorrhages, in diarrhœa, and dysentery. From a scruple to half a drachm is given morning and evening. The plant has not yet found a place in the systems of the botanists.

Co'RTEx JUBABÆ is brought to us from the East Indies; but the tree is unknown, and its powers, if we may judge from its sensible qualities, are weak. It is slightly bitter, and is recommended rather as a nervous than a tonic medicine.

Co'RTEx LAVOLA. The bark of the tree supposed to afford the ANISUM STELLATUM; q. v.

Co'RTEx CARDINALIS DE LUGO. See CORTEX PERUVIANUS.

Co'RTEx CARYOPHYLLOIDES. See CASSIA CARYOPHYLLATA.

Co'RTEx CRA'SSIOR. See CASSIA LIGNEA.

Co'RTEx CULILAWAN, a hot aromatic bark, found in New Guinea, of similar virtues to the *cortex massory*; q. v. See also CASSIA CARYOPHYLLATA.

Co'RTEx ELATERII. See THURIS CORTEX.

Co'RTEx MAGELLANICUS. See WINTERANUS CORTEX.

Co'RTEx MASSORY. It is a warm aromatic bark, found in New Guinea. It is stimulant, carminative, and stomachic. The inhabitants powder, and mix it with water, to anoint their bodies in cold wet weather. It is also used against pains and colic.

Co'RTEx PERUVIANUS. The PERUVIAN BARK; also called *cinchona*, *china china*, *kinkina*, *chinchina*, *quinquina*, *holquahuilt*, *cortex patrum*, and *cardinalis de Lugo*; JESUITS' BARK. The powder of this bark hath been sold under various names, as *fulvis comitissæ*, *patrum et Jesuitarum fulv.* &c. CINCHONA is its appellation in the new London Dispensatory.

It is the bark of a tree which grows in Peru; the *cincona officinalis* Lin. Sp. Pl. 244, the *c. macrocarpa* of the Supplementum Plantarum, and of Willdenow, vol. i. p. 958. There are four sorts of this bark, viz. the red, the yellow, the white, and the curling; the two first are the best, the curling is from young trees, but of the kinds we shall afterwards speak more particularly. Its virtues were probably discovered by the Indians about the year 1500. A lake near a town in Peru was surrounded by these trees, which were torn up by an earthquake, and falling into the adjacent water, they rendered it bitter. An Indian, urged by his thirst during a fever, drank of this water, and soon recovered: others were, by the same means, also cured. On enquiry, it was found that the water owed its virtue to the trees, and ultimately to the bark. A Spanish soldier was afterwards cured by it, and from him it was recommended to the wife of the count de Cinchon, then viceroy of Peru; hence the name CINCHONA and COMITISSA. The countess, on her recovery, distributed a large portion of this bark to the Jesuits, in whose hands its reputation was increased. After this, father de Lugo, at a great expense, brought a parcel of it to Rome, and distributed it among the religious and poor: from him it received the name of CORTEX CARDINALIS DE LUGO. From Rome it was spread into France and England, and at length became general. Such is the story gravely recorded, and industriously repeated;

but there is little difficulty in proving that all the former part is apocryphal.

This bark is brought in pieces of different sizes, some rolled up in short thick quills, and others flat; the outside is brownish, and generally hath a whitish moss spread upon it; the inside is of a yellowish, reddish, or rusty iron colour. The best sort is bitter, aromatic, resinous, breaks close and smooth, is friable between the teeth, pulverises easily; when powdered, is of a cinnamon colour, but rather paler; and the surest test of its goodness, in the opinion of some authors, is a musty smell, with so much of the aromatic as not to be disagreeable. The inferior kinds, when broken, appear woody; and in chewing, separate into fibres. That which is called female bark is redder on the inside, thicker, and, on the outside, more white and smooth, weaker to the smell and taste than the former, and in medical virtue greatly inferior. In the choice of bark we must select that which is solid, heavy, and dry, not mouldy; or whose taste is simply bitter and astringent, without aroma. That whose taste is nauseous, mucilaginous, whose surface is polished, which is tough, spongy, or powdery, should be rejected.

The bark has been subjected to all the tortures of fire, to extort the secret of those virtues which it was supposed exclusively to possess. We need not add with little success; nor can we follow all the fancies which have, at different times, been raised to the rank of theories to account for its effects. The more rational and less violent processes of modern chemists have shown, that it consists of a bitter extractive matter, tanin, and gallic acid. With these are combined mucilage and resin; but the two last are apparently a portion of extractive, formed in the analysis: at least we know that the extractive contains mucilage, and that, by long exposure to heat, almost, perhaps the whole, of the extractive may be converted into resin. M. Seguin, a chemist of some credit, has strangely supposed that the bark owes its virtues to its gelatine; and some practitioners have gravely attempted to cure intermittents and continued fevers with glue. When a physician prescribes a remedy under the bias of a system, he is generally successful. Dr. Duncan, junior, in his Analysis of Bark, has shown that it does not contain gelatine: yet its mucilage assumes a particular appearance, which has induced him to give it the name of cinconin; and it has been suspected that the bark owes its virtue to this principle.

The sensible qualities of the bark show it to be a warm tonic and astringent; excelled in its warmth by many aromatics, and in its astringency by the oak bark and the tormentil: as a stimulant, its effects are very inconsiderable. On dead animal matter it appears to be an antiseptic; yet in this quality it is exceeded by the myrrh and some other substances. Authors have consequently found considerable difficulties in explaining the sources of the benefit derived from its use. We may combine aromatics, tonics, and antiseptics, in every variety of proportion, without obtaining the advantages of the union which this natural combination offers; yet approaching so near to it, that, paradoxical as it may seem, we could, perhaps, better give up this medicine than many other articles of the materia medica. As, however, its excellence is generally allowed, it has been

styled a specific; and, indeed, from its indiscriminate use, physicians seem to have adopted this opinion.

The peculiar advantages of the bark are certainly derived from its tonic power. How far this is connected with its astringency has not been shown; yet we have laid the foundation for the enquiry under the article *ASTRINGENTIA*, q. v.; and may now add, that we consider this tonic power as connected with its astringency, joined with a peculiar proportion of aroma, which affords a slight, and seldom, if ever, an injurious stimulus. Whatever are the real effects of bark may be explained from this view; for botanical analogy does not at all assist us in the enquiry, since in its natural order we find simple astringents only of no peculiar virtues.

If the bark be given to a healthy person, it produces no striking change in the pulse, or any of the other natural functions. If continued, it is said to make the pulse fuller and slower, to increase the appetite, and often to produce costiveness. We have, therefore, little assistance from this source; and our best assistance is derived from its effects in diseases.

The variety of disorders in which the bark can be used to advantage, formerly entitled it almost to the character of an universal medicine: in many diseases it is supposed to be a sovereign remedy; but every practitioner, in proportion as his knowledge of its qualities increases, finds he can employ many other remedies with at least equal advantage.

From the history of the bark, it appears to have been introduced as a remedy for intermittent and remittent fevers of warm climates. When brought to Europe it was not less successful; not that former plans had failed, but vernal intermittents had been considered as salutary, and autumnal ones as peculiarly obstinate. The fever was supposed to be the means of concocting the matter; and, when this was effected, it was supposed that nature would discharge it. On this principle the use of the bark was opposed by regular physicians, and it was accused of producing infarctions of the liver, dropsy, &c.; while its supporters alleged that these were the effect of the disease, and, in reality, owing to its not being checked more early. Truth, as usual, probably lay between the two extremes. We are confident that these inconveniences have been derived from the injudicious use of the bark, though they may, and often do, arise from the disease itself, as will appear in its proper place.

As the bark seems to act as a tonic in consequence of its astringency, we may suspect that, from this power, it would be occasionally injurious, and it is certainly found so. The admirers of this remedy contend that it cannot be an active astringent, since it is useful in relieving glandular tumours arising from obstruction, and that it does not stop the spitting in the confluent small pox. Such assertions, which we find in the former editions of this dictionary, are owing to the want of discrimination, so frequent in its authors. When increased evacuations or obstructions are owing to, or connected with debility, the astringent power of the bark corrects the cause, and only by degrees lessens the effect. We have already noticed even a stronger case, where it is useful in peripneumonia notha arising from atonic gout, and shall have occasion to point out its efficacy in the putrid peripneumony. But when it is contended that it has been given to women successfully in the quantity of

a drachm every three hours, two days after delivery, the event is certainly misrepresented, or the circumstances concealed. We have had occasion to witness very opposite effects; and though it may not greatly lessen the *usual* flow of the menses in some cases of excessive critical evacuations from the uterus, it has been highly injurious by checking them. The expectoration, except where connected with debility, it certainly lessens; the discharge of bile it checks; and frequently the perspiration. In short, its use demands much more minute discrimination than it seems yet to have enjoyed.

In *INTERMITTENTS* its power is generally acknowledged; and it is in these a medicine of great importance, as we can often, with certainty, prevent an expected fit. This power is more valuable, as those species which attack the head would be fatal in the recurrence of another paroxysm. Yet, where we can wait the operation of laxatives, it is always safest to premise them, for reasons which we shall afterwards explain. (See *INTERMITTENTS*.) The young practitioner must not, however, too confidently expect constant success. We have often found the bark ineffectual in curing agues, in whatever way it has been tried; but *usually* to succeed is no common praise. In *remittents* the bark is equally useful; and in the malignant ones indispensable, when the irritability of the stomach will admit of its exhibition.

In every kind of *continued fever*, except the inflammatory, or the inflammatory stages of fever, the bark is said to be extremely useful, though this general axiom is not supported by our own experience. When the bowels are thoroughly emptied, it is not injurious: when debility or putridity comes on, it is useful. Yet in many cases of febrile debility, wine and suitable aliment are at least equally effectual, and the practitioner should be aware that bark, by checking the discharges from the liver and other glands of the intestines, produces an apparent debility, which purgatives alone will remove. In the yellow fever, it is lately said by Dr. De la Fuente, a Spanish physician, that it is a specific, given in large doses: six or eight ounces of bark are to be taken in the first forty-eight hours of the disease.

In the real *PHEGMASIAE* the bark is seldom admissible. Erythema and the erythematous inflammations must be excepted, and these ought to be separated from the others. Gangrenous sore throat, for instance, has not the slightest connection with quinsy, but in the part affected. An exception of importance occurs in those plegmasiae which periodically recur; yet in these the fever appears to be the radical disease, and inflammation only a symptom. It is on this foundation only that bark has been rationally employed in rheumatism or gout. Dr. Haygarth has lately offered some evidence in its favour in relieving the former disease. Yet, on a careful comparison of his facts, we think that at least equally strong evidence might be afforded for the success of more than one other plan. His authority is, however, sufficient to recommend this medicine for further trial; but of it we have had little experience.

In gout, its latest advocate has been Dr. Tavares, the archiater of Portugal. After purging, he advises it in large and frequently repeated doses.

*EXANTHEMATA* are often relieved by this remedy. *Erysipelas* in warmer regions, and in crowded cities,

often requires it; and though late experience by no means finds it eminently useful in the *plague*, as theory supposed it must be, yet there is little doubt of its utility in this disease. *Small pox*, advancing slowly, and the confluent kind maturing imperfectly, are greatly benefited by bark; but the peripneumonic tendency of *measles*, unless of a putrid kind, forbids its use. In *aphthæ*, except when symptoms of putridity come on, this remedy is not required; and as *scarlatina* is often attended with a putrid sore throat, bark is usually given. Of its utility in this disease, however, while the great heat continues, we have some doubts; but this is not the place for their discussion. The putrid forms of *miliaria*, of which we hear the report only—for we do not recollect this species of the disease to have been described in any English author—will certainly require bark; while the remitting forms of the fever attending *hemphigus* and *urticaria* seem equally to demand its assistance.

In *HÆMORRHAGÆ*, bark has been often given; but, in almost every instance, with disadvantage, except in the putrid dissolution of the blood, sometimes attending fevers, though occasionally occurring without any evident cause. Even in hæmorrhages from debility, we think that greater benefit has been derived from nitre, though the bark is sometimes necessary.

The two genera of *PROFLUVIA* occasionally require this remedy, viz. the *epidemic catarrh*, and some of the stages of *dysentery*; but, in the latter, it is very seldom useful. In other discharges without fever, it is an useful remedy in supporting the strength, and in meliorating the suppuration from abscesses.

In the *NEUROSES*, bark has been deservedly a favourite remedy. In apoplexy and palsy, while the vessels are distended, this remedy is inadmissible; but when the tension is removed, it is of the highest importance. In *tremor*, as we have observed, tonics are valuable remedies, if no organic affection occasions the complaint. In the *adynamia* it is chiefly adapted to dyspepsia and chlorosis, though injurious in hypochondriasis and in syncope, a very few cases excepted, where the disease arises from excessive evacuations. In the more violent *spasms* it is a remedy of too slow operation; though, when joined with valerian, it has been found useful in both epilepsy, hysteria, raphania, and the intervals of true spasmodic asthma. In *pertussis* it has been commended, but we suspect it to be of little real utility. *Palpitation* generally attends debility, but it is in that case scarcely a disease. It most commonly arises from a topical affection of the heart and larger arteries immediately connected with that organ, or from a source generally unsuspected, accumulations in the stomach and bowels, or plethora; and in these cases bark is inadmissible. In dyspnœa, pyrosis, colica, cholera, hydrophobia, and diarrhœa, it is usually injurious. In diabetes, of slight and doubtful efficacy. In all the spasms, recurring at regular intervals, it is a remedy of the highest value.

In the *VESANIÆ*, some species of amentia from debility excepted, it is admissible; and, indeed, in the *marcores* and *intumescentiæ*, the two first order of *CACHEXIÆ*, it is scarcely ever advantageous; for, however the diseases under the former order appear to be connected with debility, they are either attended with hectic fever, or such obstructions as are rendered more obstinate by this remedy. In *rachitis* it is sometimes given, but seldom

with advantage. Of the *impetigines*, the only genus in which it is employed, or in which any success has attended its use, is *scrofula*; but on this subject we must afterwards enlarge. In some cases of syphilis, where the bubos do not advance, or where the discharge from them is thin and acrid, the bark has been highly commended.

In the class *LOCALES*, the order of *apoceneses*, “excessive evacuations,” contain the only group of diseases in which the bark is useful; but in these we find that plethora or irritation often occasions the discharges, and the only effectual remedies are of a different kind. In these, and in the diseases of some other orders, where debility is the cause, the bark may be employed; and, indeed, it is constantly used, though not always with success.

As an antiseptic the bark has been highly commended; and in gangrenes, as well as in every case where the fluids are putrescent, it has been chiefly depended on. It, indeed, sometimes fails in the former case, where great irritation is the cause, or an attendant symptom; but, in general, it is highly useful, though modern surgeons depend less on it than their predecessors. In these instances it acts, however, as a tonic only. As such, it promotes the suppuration of the mortified part, and when it appears to meliorate in a slight degree the discharge, its chief efficacy is by accelerating the separation.

The bark is generally injurious in fevers of the inflammatory kind and in topical inflammations; yet, in some cases of abscess, where the suppuration proceeds slowly, or the discharge is thin and glairy, it has been of use. In all cases of dyspnœa, whether from inflammation or any other cause, except in the kind formerly mentioned, it is hurtful. In infarctions of the viscera, in critical discharges, unless insufficient from weakness, it is generally injurious. In many cases of different kinds, or rather, perhaps, in many constitutions, it produces a stricture on the surface from the suppression of the perspiration. It sometimes purges; at others, lies like a cold weight at the stomach. In such cases some corrective should be employed. When it produces a stricture, which most frequently happens in fever, camphor, or the James’ powder, will often obviate the inconvenience. The cathartic tendency is corrected by an opiate, and the cold heavy load by an aromatic. In every instance previous to the use of the bark, the stomach and bowels should be freely evacuated.

When the bark produces vomiting, the carbonic acid gas, or an opiate, will correct this tendency; and when it occasions costiveness, rhubarb may be added. Numerous other medicines are occasionally combined with bark, either to add to its virtues or to correct its supposed disadvantages. In fevers it has been usual to add emetic tartar or crude sal ammoniac; in stomach complaints, sulphuric acid, kali, lime water, or chalybeate preparations; in excessive discharges, sulphuric acid or alum. In each case some decomposition appears to take place, and we can place no confidence on the appropriate effects of the medicine. It is highly probable that some change occurs on the union of bark with emetic tartar, since the latter loses in a great degree its emetic power. The powder of Dr. James preserves in the combination its powers unimpaired.

In the *Species Plantarum*, published by Willdenow,

there are nine species of cincona, two of which only occur in Linnæus's own edition. These have been found in Peru, or in the American islands of St. Lucia, St. Domingo, &c. They agree in general, with the bark, in astringent and tonic powers; but possess qualities offensive to the stomach and bowels, which are lessened apparently, and would be, probably, ultimately lost by keeping. See Lambert on the genus cinchona; Vahl, Copenhagen Transactions, vol. i. ii. and iii.; Davidson, Philosophical Transactions, vol. lxxiv.

Various are the preparations of the bark; but when the stomach will bear it, the powder, if very fine, is the most agreeable and the most useful. If the powder cannot be taken, the *infusion* has been preferred; but where the active power of the bark is necessary, the infusion is a very weak inadequate preparation.

**INFUSION OF THE BARK.** To one ounce of bark in fine powder, add twelve ounces of soft water by a little at a time, continuing to triturate it for about ten minutes in a marble mortar; then let them stand together, without subjecting them to any heat, for twelve hours, and strain. If the water is poured on hot, the time necessary for the infusion may be less; and, indeed, with cold water, many pharmacologists, after trituration, allow only of the infusion for an hour or two. The elegance and strength of the infusion are increased by the addition of a small quantity of French brandy during the triture. In this preparation, the component parts of the bark are not separated. It is a solution with little change. In weak stomachs it is preferable, but its powers are inconsiderable.

In boiling, the bark is partly decomposed. The extractive matter, by the addition of oxygen, becomes a resin, dissolved while the water boils, but separating on cooling.

In decoction, the London college orders, for this reason, the bark to be boiled for a very short time in a covered vessel. An ounce is ordered to be boiled in a pint and quarter of pure water for ten minutes only.

Next to the infusion and decoction, an infusion in Rhenish wine may be preferred; and the tincture drawn with good French brandy follows. In *SCROFULA*, the shell lime water is said to be a good menstruum for the bark; and in cases where relaxation simply demands the use of the bark, the lime water made with stone lime should be preferred.

The addition of magnesia to the bark during the trituration, previous to the infusion, renders the colour much deeper, and is supposed to add to the strength of the preparation. A decomposition seems, in this instance, to take place; and it is, we think, still doubtful whether this infusion is really preferable as a medicine.

The unpleasant taste of the bark is covered by liquorice, orange peel, or a small quantity of winter's bark. In the following electuary, mucilage is thought useful in concealing the taste, and it is considered as an excellent medicine in scrofulous cases, equal to burnt sponge. *R. sodæ pp. ʒ ij. pulveris cort. Peruv. ʒ i. mucilaginis gum. Arab. q. s. m.* The dose ʒ ij. two or three times a day.

The college of London directs the following extracts from the bark.

**EXTRACT OF PERUVIAN BARK.** Take of Peruvian bark, coarsely powdered, one pound; distilled water, twelve pints; boil for an hour or two, and pour off the

liquor, which, while hot, will be red and pellucid, but as soon as it grows cold it becomes yellow and turbid; boil the bark again in the same quantity of water as before, repeating the operation till the liquor remains transparent when cold: then evaporate all the decoctions, strained and mixed together, to a proper consistence. Ph. Lond. 1788.

This extract is to be prepared under a double form; one of the consistence of a pill, the other hard enough to be reduced to powder.

It is not so active in its powers as is imagined, and it is difficult to prepare it without some degree of empyreuma; nor does the advantage of its form compensate for the expense and trouble. Ten grains of the hard extract are computed to be equal to half a drachm of the bark in powder, but it is scarcely superior to an equal weight of the powder.

**EXTRACT OF PERUVIAN BARK WITH RESIN.**—Take of Peruvian bark, coarsely powdered, one pound; rectified spirits of wine, four pints; digest for four days, and then pour off the tincture; boil the residuum in ten pints of distilled water to two; then strain the tincture and decoction separately, evaporating the water from the decoction, and distilling the spirit from the tincture, until each begins to be thickened; lastly, mix the resinous with the aqueous extract, and make the mass fit for forming into pills. Pharm. Lond. 1788. This extract is greatly inferior to the former, and seldom employed.

The extracts are in general carelessly and imperfectly prepared, and among the venial faults we may mention, that, when the evaporated decoctions have attained the consistence of honey, they are brought to that of an extract by adding the powder of bark. The operator thus avoids the most troublesome part of his labour, the cautious regulation of the fire, and the constant stirring when it approaches the form of an extract.

We have lately received, it is said, from South America, a very elegant preparation, supposed to be an inspissation of the decoctions by exposure to the sun in its native climate. It is by far the most efficacious of the extracts; but we suspect that it is often, at least, the common extract prepared with peculiar care. Some years since a preparation was sold under the title of the essential salt of bark. It was an extract full of flaky salts, tasting strongly of bark; but as it is no longer known, we may suppose that its efficacy was not considerable.

**TINCTURE OF PERUVIAN BARK.** Take of the Peruvian bark, four ounces; of proof spirit of wine, a quart; digest with a gentle heat for eight days, and strain. Pharm. Lond. 1788.

This is an agreeable preparation, but it is too heating if a large dose is given. It would be better to add twice the quantity of bark to this proportion of spirit, if the menstruum would dissolve it, which we believe would not be the case.

**COMPOUND TINCTURE OF BARK.** Take of Peruvian bark in powder, two ounces; exterior peel of Seville oranges, one ounce and a half; Virginia snake root bruised, three drachms; saffron, one drachm; cochineal powdered, two scruples; proof spirit of wine, twenty ounces; digest for fourteen days, and strain. This was the *tinctura corticis Huxhami*, and is certainly a good cordial; but it derives little additional virtue from the

saffron or cochineal. The snake root and orange peel warm, slightly, a preparation sufficiently heating before.

*Tinctura ammoniata cinchonæ.*—AMMONIATED TINCTURE OF BARK. Take of Peruvian bark in powder, by weight, four ounces; compound spirit of ammonia, two pounds; digest them in a close vessel for ten days, and filter it. Pharm. Lond. 1788. This is a very weak preparation of the bark, and seldom employed. See Lewis's *Materia Medica*. Neumann's *Chem. Works*. Percival's *Essays*. Cullen's *Materia Medica*.

CO'RTEX PERUVIANUS RUBER. The red Peruvian bark is in much larger and thicker pieces than the common bark. It evidently consists of three different layers. The external is thin, rugged, and frequently covered with a mossy substance, and of a reddish brown colour; the middle is thicker, more compact, and of a darker colour; in this appears chiefly to reside its resinous portion, since it is extremely brittle, and evidently contains a larger quantity of inflammable matter than the similar part of any other kind of bark. The innermost hath a more woody and fibrous appearance, of a brighter red than the former. The entire piece breaks in that brittle manner described by writers on the *materia medica*, as a proof of the superior excellence of the bark. In reducing it to powder, the middle layer, which seems to contain the greatest proportion of resin, will not give way to the pestle so easily as the other layers: and this should be particularly attended to when it is used in fine powder. In flavour, chiefly discoverable either in powder or solution, it is evidently more aromatic, and has a greater degree of bitterness than the common bark.

It is highly probable that this is the bark of older trees than that which is called quill bark, or from their trunks and larger branches; and more particular care is probably taken in collecting and drying it.

The taste and flavour of the red bark are more difficultly evolved, and are, therefore, at first not so obvious, from the closeness of its texture, and from the resinous coat being so well defended and inclosed between the other layers. It is evidently heavier than any other kind of bark, and is so much warmer that it would seem to answer all the purposes derived from the union of aromatics or serpentaria, recommended in the obstinate quartan intermittents of elderly people.

By the testimony of many practitioners, it appears that intermitting fevers are more speedily and effectually cured, either by infusion, decoction, or powder of the red bark, than by those of the common bark; and this also by smaller doses of the former than of the latter. Dr. Saunders observes, that from the numerous trials he has made with it in intermitting fevers and other diseases, he is disposed to conclude that it need be employed only in half the quantity we generally recommend of the other bark. We must add with regret, that we seldom meet with bark of this superior quality at present. Our red bark is often only the coarser pieces artificially stained.

The infusion, decoction, and tincture, made with red bark, are considerably stronger than those from the same quantity of common bark; and it is said to have afforded more than twice the quantity of extract than is obtained from the same portion of common bark.

Dr. Saunders relates the following experiment, in

his observations on the superior efficacy of the red Peruvian bark. A decoction of both red and common Peruvian bark was prepared by taking an ounce of each, and boiling them in a pint and a half of water, to one pint; the former had greatly the superiority in strength and power. A pint of fresh water was added to each decoction; the boiling still continued till that quantity was evaporated. The decoction of the common Peruvian bark seemed gradually to lose its sensible qualities, while that of the red bark still retained its own. The same quantity of water was added as before to each, and the decoction repeated until a gallon of water was exhausted; at the expiration of which time the common Peruvian bark was rendered almost tasteless, the red bark still retaining nearly its former sensible qualities.

In an infusion of the red bark, the spirit of vitriol lost its acidity more perfectly than in an infusion of the bark before in use. A decoction of the red bark keeps perfectly good during more than a month in the summer season, whilst that of the common bark is sensibly changed in a few days. In the decoction of the red bark, the powder, which is separated during cooling, remains intimately diffused through the liquor, so that it continues loaded and turbid whilst at rest: in the decoction of the common bark it separates, and easily subsides to the bottom.

CO'RTEX FLA'VUS. See FLAVUS CORTEX.

CO'RTEX POEGEREBAE is a bark whose country is unknown. It is styptic and bitterish; said to be useful as an astringent in old diarrhœas, and occasionally in dysentery.

CO'RTEX WINTERA'NUS SPU'RIOUS. See CANELLA ALBA.

CORTICA'LIS SUBSTA'NTIA, (from *cortex*, the bark). The CORTICAL SUBSTANCE OF THE BRAIN. See CEREBRUM.

CORTICA'TUS, (from *cortex*, bark). In botany it means in a skin or rind.

CORTU'SA. See SANICULA MAS.

CO'RU CANA'RICA, *Lusitanis Malabarica herba*. It is a dwarf tree, with yellow flowers, and leaves resembling those of the peach tree. The bark of the tree, if wounded, distils a copious milky juice, which is much used in Malabar against alvine fluxes. Its genus is unknown. Raii Hist.

CORYCOMA'CHIA, and CO'RYCUS, (from *κορυκος*, a ball, and *μαχη*, contention). A small ball made of leather, and stuffed with bran, or sand, or other materials: it was suspended by a string about the height of the navel of the person who used it. When people were too fat, they took it in both hands and pushed it from them, and receding as it returned, they received it into their hands, and so continued the exercise. See SPHERISTICA.

CORYDALES, (from *κορυς*, a helmet or hat). A natural order of plants resembling a hat or helmet.

CORYLUS. (Greek). See AVELLANA.

CORYMBAS, or CORY'MBL, (from *καρυ*, the head). The IVY TREE. So called because it grows into a large head on the top. See HEDERA ARBOREA.

CORY'MBUS, (from *corymbe*, the ivy). A cluster of flowers or fruit standing on pedicles, which are so disposed as to form a sphere. In its proper acceptation it is a cluster of ivy berries. Linnæus distinguishes

by this name a species of inflorescence, in which the flowers grow in clusters, each upon a separate peduncle as on the siliqueose plants in general.

**CORYPHE.** *Κορυφή*. The vertex or top of any thing. See **VERTEX**.

**CORYZA**, (from *καρυ*, the head, and *ζωω*, to boil; because it is attended with an inflammatory defluxion from the nose). See **GRAVEDO** and **CATARRHUS**.

**COSCU'LIA**. The grains of kermes. See **CHERMES**.

**COSMETICA**. Medicines which take off pimples or other irregularities of the skin. They are usually saturnine or other metallic preparations, and often highly injurious. The celebrated wash of Gowland is a weak solution of corrosive sublimate. Antimonials taken internally are safe and useful.

**COSMETO'RGES**. A word, invented by Dolæus, to express the sensitive soul.

**COSMIA'NA ANTIDO'TUS**. The name of an antidote in Marcellus Empiricus.

**CO'SMOS**. Rythmus, a regular series. In Hippocrates it is the order and series of critical days.

**CO'SSI**, (from *κισ*, a worm). Tubercles in the face, like the head of a worm. See **VARUS**.

**CO'SSUM**. A malignant ulcer of the nose, mentioned by Paracelsus.

**CO'STA PULMO'NARIA**, and **CO'STA HE'RBAPANO'NICA**. See **HIERACIUM ALPINUM**.

**CO'STÆ**, (from *custodiendo*; because they surround and keep in the lungs). The **RIBS**. The *costæ*, in anatomy, are generally twelve on each side, sometimes eleven, at others thirteen: their extremities next the vertebræ are rounder and stronger than those which join the sternum; the upper edges are more round than the lower, which are depressed internally for lodging the intercostal vessels and nerves; this channel is not observable at either extremity, which directs us to perform the operation for the empyema rather at the sides of the thorax than near the sternum or spine.

The ribs are articulated at each extremity, of which the posterior is doubly joined to the vertebræ; for the head is received into the cavities of the two bodies of the vertebræ by ginglymi, and the larger tubercle is articulated to the transverse process of the inferior vertebræ by arthrodia; they are thus guarded against luxations.

They are divided into true, called *veræ*, and false, called *spuriæ*, *illegitimæ*, *mendosæ*, *nothæ*. The true are the seven superior, whose cartilages are joined to the sternum; these ribs include the heart and lungs. The false are five inferior, whose cartilages are not joined to the sternum; unto all these the diaphragm is connected, and within them the stomach, liver, &c. are contained.

The cartilages of the false ribs are only connected to one another by the membrane which covers them; the two last are joined to the vertebræ by a round head, and their cartilaginous extremities are lost in the interstices of the muscles, so that they are more moveable than the other ribs.

The upper rib, contrary to the rest, is flat upwards and downwards, that it may not incommode the lungs, and leave room for the subclavian vessels and muscle.

The anterior extremity of each rib is lower than the posterior; therefore, when elevated, the cavity of the thorax will be increased in its diameter backwards and

forwards, and the middle part of the superior ridge is lower than the posterior part; thus, when elevated, the diameter of the thorax will be laterally increased.

The ribs are but little used in sleep, respiration being then chiefly carried on by the diaphragm.

**Co'stæ**, in botany. The fibres of the leaves, or the long strings which run either across or lengthways through them, are called their ribs.

**COSTA'LES NE'RVII**, (from *costa*, a rib). See **DORSALES**.

**COSTO-HYOIDÆ'US**, (from *costa*, a rib, and *hyoidæus*, belonging to the hyoid bone). A muscle so named from its origin and insertion. See **CORACO-HYOIDÆUS**.

**CO'STUS**, *costus arabicus* Lin. Sp. Pl. 2, (from the Arabic term *kasta*). Also called *costus Indicus*, *amarus dulcis Orientalis*, *tsianakua*. SWEET AND BITTER **COSTUS**.

It is a root brought from the East Indies; about the size of a finger, of a pale greyish colour outwardly, and yellow within. In Arabia a bitter and a sweet sort were formerly distinguished; and in commerce three kinds are occasionally found, derived either from the anomum, the costus, or the alpinia of Linnæus.

The root of costus is recommended as stomachic, diaphoretic, and diuretic; it impregnates the urine with a violet smell. On evaporating a decoction of this root, almost all its smell is dissipated; but a bitter extract is obtained nearly equalling two thirds of the root. The spirituous extract is but small in quantity. Rati Hist. Lewis's *Materia Medica*. See **ZEDOARIA**.

**Co'stus cortico'sus**. See **CANELLA ALBA**.

**Co'stus horto'rum minor**. See **AGERATUM**.

**Co'stus ni'gra**. See **CINARA**.

**CO'STILE**. The socket of the hip bone. See **ACETABULUM**.

**COTARO'NIUM**. A word coined by Paracelsus, implying a liquor into which all bodies, and even their elements, may be dissolved.

**CO'TINUS**. (Greek). The *olive* of the Greeks; the *red sumach* of the moderns.

**CO'TIS**, (from *κοτήν*, the head). The back part of the head; sometimes the hollow of the neck.

**COTONA'STER**. See **SORBUS**.

**COTO'NEA**. See **CYDONIA**.

**COTO'NIUM**. See **BOMBAX**.

**CO'TTI VI'NI**. A name of some Italian wines rendered luscious by boiling the must of the poorer sorts.

**CO'TULA**. (See **COTYLE** and **CYATHUS**). A twelve ounce measure; and sometimes the appellation of bugs. See **CIMEX**.

**CO'TULA FLO'RE LU'TEO RADI'ATO**. See **BUPHTHALMUM**.

**CO'TULA FÆTIDA**, (from *cos*, a whetstone). A kind of camomile, with leaves like a whetstone. See **CHAMÆMELUM FÆTIDUM**.

**CO'TYLA**, (from *κοτύλη*, a cavity). See **COTYLE**. It is any deep cavity in a bone, in which any other bone is articulated; but generally used to express the cavity which receives the head of the thigh bone. It also signifies a deep sinus surrounded with large lips, or any cavity like the glene, but deeper.

**COTYLE**, **CO'TYLA**, or **CO'TULA**, (from the

same). Among the ancients it was a drinking cup, or any thing which had a cavity, as the hollow of the hand. Among the Greeks it was a measure, and is nearly the same as the hemina of the Romans, which held nine or ten ounces. See CYATHUS.

**COTYLEDON'S**, (from the same). **COTYLEDONS**; *acetabula*; certain glandular bodies adhering to the chorion of some animals: but no such substances are observed in the human chorion.

**COTYLEDON**, (from *κοῦλη*, *cavity*). The lateral bibulous, perishable lobe, or placenta of the seed, destined only to nourish the heart. The greater part of seeds have two lobes; some have more; some only one, and others none: hence a distinction of all plants into *acotyledones*, *monocotyledones*, *dicotyledones*, *polycotyledones*. (See BOTANY.) Some herbs, also, whose leaves are concave, and shaped like the cavity of the hip joint, bear this name.

**COTYLEDON**, (from *κοῦλη*, *a cavity*.) *Cotyledon umbilicus veneris* Lin. Sp. Pl. 615. *Acetabulum*, *cotyledon major*, KIDNEY WORT, NAVEL WORT, and WALL PENNY WORT.

Its whole appearance resembles house leek; the root thick, knotted, with many small fibres springing from it. It grows on old stone walls, and flowers in May. The leaves are slightly cooling, astringent, and diuretic; but are seldom used.

**COTYLEDON MARINUM**. See ANDROSACE.

**COTYLEDUM, A'LTERUM**. See CRASSULA.

**CO'UM**. See COLCHICUM.

**COUP DE SO'LEIL**. See ICTUS SOLARIS.

**COU'RADI**. See PAIANELI.

**COU'RAP**. (Indian.) The modern name for a distemper very common in Java and other parts of the East Indies. It is a herpes on the axillæ, groins, breast, and face; the itching is almost perpetual, and the scratching is followed by great pain, with a discharge of matter, which fixes the linen firmly to the skin. Courap is a general name for any sort of itch; but this distemper is thus called by way of eminence. It is so contagious that few escape it. For the cure gentle and repeated purging, and externally the sublimate in a small quantity, are employed. See Bontius de Medicina Indorum.

**COU'RBARIL**. The American name of the tree which produces the gum anime. Called also *locusta*; *animifera arbor Brasiliana*; *Brasiliensis arbor siliquosa*; *cancamum Græcorum*; *ceratia diphyllus*; *ictaiba*; **COURBARIL**. *Hymenæa coubaril* Lin. Sp. Pl. 537. It grows in many parts of the West Indies, particularly in the Brasils. See ANIME.

**COURO'NDI**. It is a tall evergreen, which grows in the East Indies; the juice of its leaves and the kernels of its fruit are astringent, and used with whey to cure diarrhœas and dysenteries. Rheed's Malabar, 4 tab. 50. Raii Hist.

**COU'ROS**. So Hippocrates called the child in the womb when perfected there. See CONCEPTIO.

**COUROY-MOE'LLI**. A shrub growing in sandy places in the East Indies: the bark and root boiled in milk are esteemed an antidote against the poison of serpents. It has not yet found a place in botanical systems. Raii Hist.

**COU'SCOUS**. The African name of a paste made of the flour of millet, with some flesh; and, when eaten,

a small quantity of *lalo* is also put. It is much used as food about the river Senegal.

**COU'TON**. A tree which grows in Candia, resembling the walnut tree; *arbor vinifera couton juglandi similis* of Bauhine. When this tree is wounded, an agreeable liquor flows out, which resembles Orleans wine. Its genus is unknown.

**CO'VALAM**; called also *cucurbitifera trifolia*, &c. *beli*, seu *serifole Bengalensium*, *capotes*, *cydonia exotica*. *Cratæva marmelos* Lin. Sp. Pl. 637.

It is a tall tree, growing in Malabar, and in the island of Ceylon: its fruit is shaped like an apple; the outer rind is thin and green; under it is a woody one, inclosing a viscid yellowish moist substance, of a sweetish acid taste, in which are long, flat, white seeds; it is turgid, with a gummy pellucid juice. This fruit is astringent whilst unripe; but when ripe, of a delicious taste. The bark of the tree strengthens the stomach, and relieves hypochondriac languors. Raii Hist. A species of sterculia, called *tongchu*, greatly resembles this plant, of which M. Correa has formed a new genus. Linnæan Transactions, vol. v.

**COU'VRE CHEF, LE GRAND**. **COU'VRE CHEF, EN TRI'ANGLE**. See RICÆ, DELIGATIO, 5, 7.

**COWPE'RI GLANDU'LÆ**. **COWPER'S GLANDS**, from the discoverer. They are small, hemispherical, and compound. One of them is situated on each side of the urethra, without the corpus spongiosum and acceleratores muscles, between the bulb and prostate. Each has an excretory duct, through which a mucus is evacuated upon the internal surface of the urethra for its defence. Whether there be other glands belonging to this part, as some authors assert, is uncertain. In women we observe, before the hymen, an orifice on each side, from Cowper's glands, which lie upon each side of the perinæum, and serve the same purpose as in the male. They are called also *muscosæ glandulæ*, and *glandulæ vasculares*.

**CO'XA**. See FEMUR.

**CO'XÆ DOLO'RES**. See ISCHIADICUS MORBUS.

**CO'XÆ O'SSA**. See OS INNOMINATUM.

**COXE'NDIX**, (from *coxa*, *the hip*). See ISCHIUM, and OS INNOMINATUM.

**COYU'TENA LUZO'NIS**. See FAGARA MAJOR.

**COZTIECZO'COTL**. See MECAXOCOTLIFERA.

**CRAB LICE**. A species of pediculus, which infests the axillæ and pudenda. They fix to the skin, and are with difficulty removed. They are, however, easily destroyed by slight mercurials, either in an ointment or lotion.

**CRAB YAWS**. A name in Jamaica for a kind of ulcer on the soles of the feet, with callous lips, so hard that it is difficult to cut them. The unguentum hydrargyri fortius is the best remedy.

**CRA'DE**. In Hippocrates it is the branch of a fig-tree.

**CRA'DLE**. A moveable bed to lull children to sleep; and a case in which broken limbs are placed, whose arched top prevents inconvenience from the weight of the bed clothes.

**CRÆ'CA MA'JOR**. See VICIA.

**CRÆ'PALE**, and **CRA'PULA**, (from *καρφα*, *the head*, and *πάλλω*, *to agitate*). A disorder of the head, produced by excess both in eating and drinking. INDIGESTION.

CRA'MBE, (from the Arabic word *caromb*). A CABBAGE. See BRASSICA.

CRAMBETON. (See CUCUTA.) In Hippocrates it signifies a decoction of cabbage, (from *κράμβη*, a cabbage).

CRAMPUS, CRAMP, (from *krinphen*, to contract; Germ.) It is a sudden and violently painful rigidity or spasm of a muscle. This complaint is often very troublesome, but not usually dangerous; though instances have occurred in which, passing from the limbs to the bowels, the patient hath with difficulty recovered: it principally affects the limbs or neck.

In the Medical Museum, vol. iii. is an instance of a cure effected by drinking a glass of tar water every night and morning. For present relief a roll of brimstone is recommended to be held firmly in the hand, which quickly breaks, and thus the patient is eased: it breaks, however, from the heat only; yet a violent exertion of some other muscles contributes to relieve it. This disease is either idiopathic or symptomatic. When of the former class, it affects the legs, thighs, or other parts suddenly, whilst swimming in cold water, or whilst the tibiae are exposed to the cold night air; or when the muscles are uneasily situated: the digastric muscles are subject to this complaint; whilst the neck is exposed naked to the cold air the pain is intolerable, but in a minute or two abates spontaneously, particularly if warmth with friction is applied to the parts, if the contraction of the muscle is counteracted by external pressure, or the part affected be placed in a situation where extension may be produced.

The sympathetic cramp is that which affects the lower extremities, particularly in the cholera morbus, with strong distention and excruciating pain of the calves of the legs: all the flexor muscles of the legs and thighs occasionally suffer from this cause. After a vomit has been premised, thirty or forty drops of liquid laudanum should be administered. If the breast should be affected with this spasm, a fugitive pleurodyne arises, which is temporary, but violent, with danger of suffocation; if the throat, a spasmodic angina.

CRANEIA. See CORNUS.

CRA'NGON; also called *squilla crangon*, and the PRAWN. It is a sea shell fish of a delicate flavour, affording a light and easily digestible food.

CRA'NIOLOGY. We have introduced this subject in the article CEREBRUM, and have there laid the foundation of the present inquiry, by considering the brain as the material organ of an immaterial principle; as the instrument rather than the agent. The faculties of the soul are found only in animals which have a brain, are generally proportioned in their extent and variety to the size of the brain, are injured or destroyed by the lesion or destruction of this organ.

We find also the intellectual faculties independent of each other; and, even when they exist apparently in the same perfection in one individual, they are exercised with different degrees of activity at different times. This independence of the faculties is a position of considerable importance in Dr. Gall's system, our chief object at present; because he at once draws a consequence from it, that faculties, thus independent in their nature, are not connected in the organ, and that the evolution of the organs is in the direct ratio of the corresponding faculties. We doubt whether the conclusion is correct; nor,

indeed, do we see, if it be admitted, how the author can refuse to allow of the division of what is immaterial, a solecism in physics, or separate independent powers acting in different parts; in fact, of as many souls as there are faculties. Dr. Gall thinks, however, that the evolution of different faculties is the cause or effect of distinct protuberances of the cranium, and that the peculiar mental power of the individual may be ascertained by inspecting the skull.

With these views he has compared the skulls of animals and those of men, whose faculties are analogous or contrasted. His inquiries have, it is said, not only ascertained the facts to be hereafter mentioned, but proved that the faculties called instinctive in animals, as attachment, cunning, circumspection, &c. are found equally in man; that the bulk of the organ determines the genus, while the reciprocal proportion characterizes the individual; that the disposition to every faculty, given originally by nature, may be expanded by exercise or favourable circumstances, sometimes even by diseases; but that it can never be created, where nature has not originally given it. The accumulation of the organs, he remarks, is made in a regular manner from behind forward, and from below upward; so that animals, in their approach to man in the variety of their faculties, have the superior and anterior parts of the brain more expanded. In the most perfect animal, man, there are, in the author's opinion, organs in the anterior and superior parts of the frontal and parietal bones, destined for the faculties, which belong exclusively to him. In this view Gall's system entirely corresponds to the observations of Camper on the facial line, noticed also in the article CEREBRUM; q. v.

But though we have spoken of the bulk of the brain, as distinguishing the possession of intellectual faculties in their greatest variety and extent, yet bulk alone does not more furnish the criterion of intellect, than the size of the body does that of strength. Many large unwieldy men are much weaker than those of a smaller size, whose limbs are firmly knit, and whose muscles display, by their swell, the effects of frequent and spirited exertion. A large round head, in the same way, shows a feeble intellect; while the varied bold projections of the cranium display, it is supposed, varied and active mental powers.

Dr. Gall, who first promulgated this system at Vienna, has been since travelling through Germany, to increase his collection of skulls, and to improve the nice arrangement of faculties from a view of the cranium. We lately heard of him in Saxony; where he is said by professor Boetiger, who accompanied him, to have been very successful in ascertaining the qualities of the mind by this new kind of physiognomy. He has never published his lectures; but we are led to expect a full account of his system from Dr. Bishoff and Dr. Hufeland, translated into English. We shall, however, give at present the outline, and correct or supply what may be erroneous or deficient in another article. The subject will again recur under ORGANOLGY.

As a plate will render long descriptions unnecessary, we shall refer to an engraving, copied from one in the 55th volume of the Journal de Physique, for the different parts of the cranium, which designate particular qualities of mind; and shall here add a few of the singular, and sometimes, we think, trifling or ridiculous

observations by which Dr. Gall endeavours to establish his system. A system-builder will often stoop very low for assistance in support of his fabric.

In conformity with his opinions, before hinted at, he considers the medulla oblongata as the seat of the *organ of the tenacity of life*. The bulk of this part is proportional to the size of the occipital hole; and he finds it larger in women than in men, proportionally very large in the cat, the beaver, the weasel, &c.

The *organ of lasciviousness* is, in his opinion, at the basis of the skull, behind the medulla oblongata. It is only conspicuous about the age of puberty, and in castrated animals is never observed. In the ape, the rabbit, and the cock, this part of the skull is very large. It is peculiarly large in pigeons and sparrows, so as almost to form an epiphysis; and, in some human skulls of idiots distinguished for lasciviousness, this part was very protuberant.

The *organ of attachment* is peculiarly large in spaniels, and less visible in greyhounds.

The *organ of courage*, contiguous to those of "parental affection and attachment," explains, in our author's opinion, the exertions of courage from animals and human beings, in defence of their young or their particular friends. This organ is very inconsiderable in the hare, the sheep, and the greyhound; but very conspicuous in the hyena, the lion, the wolf, and particularly in the bulldog. Mr. Gall adduces as a proof of the existence of the organ of courage, the coward, when affrighted, "scratching the back part of his head behind his ears, as if he wished to excite its action!!"

The *organ of cunning* is nearly connected with that of pillage. We mean not to be ludicrous when we add, that our author found it in *poets* (Journal de Physique, vol. lv. p. 206, note). It is very conspicuous in the heads of Calmucs, in foxes, cats, pies, &c.

The *organ of the sense of locality* constitutes, with respect to places formerly seen, local memory; with respect to future objects, combinations of new localities. This organ is particularly conspicuous in birds of passage, in landscape painters, and in the skull of the great Frederick. It is fainter from age. The frontal sinus enlarges inwardly, and diminishes this portion of the brain.

The *organ of the sense for collecting or remembering facts* is subject to a similar change from age. Among animals, it is chiefly conspicuous in the elephant. "Among men (we now employ Dr. Gall's own words) I have found this organ not only in those who have a retentive memory for facts and things, but in those who have what are called systematic heads; who arrange their facts, and draw conclusions from them: in those who possess a quick perception, and are distinguished by an anxiety of knowing every thing. It even appears that the operation of combining facts, to draw conclusions from them, is the chief action of this organ: at least the elephant, who conceals the water in his trunk to pour on the person who offended him the day before, arranges many facts, and draws from them a truly logical conclusion; nor is there any other organ in the elephant's head to which we can refer this power. The involuntary motion of a man, who perceives that he has reasoned incorrectly, supports these suppositions: he strikes the middle of his forehead."

The *organ of painting* and the distinction of colours

Gall has found in many great painters, and has particularly noticed it in a head of Raphael.

The *organ of the musical sense and articulate sounds* is very distinguishable in singing birds, in the jay and parrot; but does not exist in those whose notes are harsh and inharmonious. He found it very conspicuous in the heads of Gluck, Mozart, Haydn, and Pleyel. The *organ of verbal memory* is distinguished by remarkable projections of the eyes.

The *organ of liberality lessens* as a man grows old: in fact, he then becomes avaricious. It is very near the organ of painting and music; and this, he thinks, is the reason why men of such talents are generally prodigal. We wish he could have examined the head of Gainsborough!

The *organ of the metaphysical spirit* is found in the heads of the ancient philosophers, particularly Socrates; among the moderns in Kant.

The *organ of goodness* forms that oblong elevation found constantly in the heads of Christ and the Virgin, painted by Raphael and Corregio; and contributes to convey the ideas of gentleness and goodness, which are so attractive. It is found in the skulls of all who are naturally good, and is wanting in those who are wicked. Animals of prey have no vestige of this organ.

The *organ of music and of theatrical talents* Gall has found in all the great singers and actors. In those who are born deaf, and are consequently dumb, it is very conspicuous; as they are obliged to depend on gestures for the conveyance of their ideas.

The *organ of religious veneration* is on the top of the frontal bone; and it is this, observes M. Gall, which has probably induced all races of mankind to look for their divinities in the superior regions, since "there is no philosophical reason why we should not place them below as well as above ourselves."

The organs described by Dr. Gall are thirty-three in number, which the plate, with the explanations, will point out. These are some of the most singular of his remarks; and from them our readers may form a judgment of his abilities, and the probability of his system.

**CRA'NIUM**, (quasi *κρανιον*, from *κραν*, the head). Called also *calva*, and *calvaria*, *cerebri galca*. The **SKULL**. It is that part of the head which is covered with hair: besides the os frontis, it consists of the two parietalia, the two temporal, the occiput, the os ethmoides, and os sphenoides. (See **CAPUT**.) As to the medicinal virtues of the human skull, they differ not from those of other bones. It was formerly given in epilepsy; but the intention was to excite horror, as the bone was to be a part of a man who had died a violent death.

**CRA'NTERES**, (from *κρανω*, to perform). See **SAPIENTIE DENTES**.

**CRAPULA**. (See **CREPALE**.) It is also *κραπιλα*, a SURFEIT. A disorder from something taken into the stomach, and occasioning sickness, or at least a loathing of the offending matter. It sometimes signifies a plethora, from indolence, and full but improper feeding; in which case perspiration is checked, and eruptions formed on the skin: this is sometimes called the *cholera accidentalis*. See **CHOLERA MORBUS**.

A surfeit from animal food is best remedied by a vomit, even though a vomiting and purging attend. For the management in cases of poison, see **VENENUM**.

When an excess of feeding is the cause, after an evacuation of the stomach and bowels, rigid abstinence is for a time peculiarly necessary; and after the symptoms of sickness disappear, the bowels should be kept free, food very gradually allowed; and the intervals between the meals should be considerable.

CRA'SIS, (from *κραννυμι*, to mix). The temper or consistency of the blood peculiar to every constitution.

CRASPE'DON, (from *κρημνω*, to hang down). See HYPOSTAPHYLE.

CRA'SSA ARTE'RIA, (from *crassus*, large). See AORTA.

CRA'SSA ME'NINX. See DURA MATER.

CRA'SSA INTE'STINA. See INTESTINA.

CRASSAME'NTUM, the coagulated portion of the blood when suffered to cool at rest; containing the gluten, the fibrin, and the red globules. See BLOOD.

CRA'SSENA. Saline, putrefactive, and corrosive particles, which produce ulcers and tumours of various forms. Paracelsus.

CRA'SSULA, (from *crassus*, thick; so named from the thickness of its leaves). Called also *faba crassa*, *faba inversa*, *sedum telephium*, *fabaria*, *anacampteros maxima*, *cotyledum alterum*, *scrofularia media vel tertia*, *acetabulum alterum*. COMMON ORPINE, or LIVE LONG. The sort used in medicine is the *sedum telephium* Lin. Sp. Pl. 616.

It is a plant with unbranched stalks, clothed with thick, fleshy, oval leaves, but producing no leaves immediately from the root: the flowers stand in form of umbels on the top of the stalk, and are followed each by three, or four, or six, pods full of small seeds: the root is irregular and knobby. It is indigenous in England, and perennial.

Common orpine, with the leaves slightly or not at all serrated, grows in hedges and shady grounds, hath reddish or whitish pentapetalous flowers. The leaves are cooling, but their power seems too inconsiderable for a place in practice. They are applied to inflamed hæmorrhoids, and sometimes to paronychia.

CRA'SSULA MINOR. See SEDUM.

CRATÆGUS, (from *κρατος*, strength; so called from the strength and hardness of the wood). The WILD SERVICE TREE.

CRATÆGUS ALPI'NUS. The WHITE BOAM TREE. See ARIA.

CRATÆGUS OXYCA'NTHA. See SPINA ALBA.

CRATÆGONUM, (from *κρατατος*, strong, and *γινωμι*, nascor, to make; so named from its strengthening virtues). See MELAMPYRUM.

CRATE'VÆ SI'UM. See NASTURTIIUM AQUATICUM.

CRATI'BULA, CRATI'CULA, (from *craticula*, a gridiron). The iron bars or grate which cover the ash-hole in chemical furnaces.

CRATICULA'RIS, (from the same). Bread boiled on the grate of a furnace, or on a gridiron.

CRA'TON. See CATAPUTIA MINOR.

CRE'A. See TIBIA.

CRE'BER. FREQUENT. From the Hebrew term *kebor*. It is applied to respiration, and to the pulse, when the intervals betwixt each respiration, or each pulsation of the artery, are short.

CREMA'STER, (from *κρεμνω*, suspendo, to suspend). These muscles are also called *suspensorii testium*.

They arise from the inside of Poupart's ligament on each side, run to the perforation where the seminal cord passes out, and expanding over it, make part of the tunica vaginalis communis. The course of this muscle being very oblique, makes the spermatic cord seem much more so than it really is. Their use is to draw up and suspend the testes.

CRE'MER. The name of a distemper endemial in Hungary, which seems to resemble crapula. It is cured by drinking a small quantity of any cordial water.

CRE'MNOI. The lips of ulcers, also the *labia pendendi*, (from *κρημνω*, a precipice, or shelving place).

CRE'MOR, (from *κρημνον*, lactis crumen, a crinæ, scerno). It is the expressed or strained juice of any grain, particularly of barley boiled till it be so soft as to pass through a strainer (see PTISANA); also the cream of milk. See CHYLUS and LAC.

CRE'MOR CALC. VIV. The cream or flour of quick lime is the calcareous earth, which, having regained the carbonic acid from the air, is insoluble in water.

CRE'MOR LITHARGY'RI ACETA'T. See PLUMBUM.

CRENA'TUM, (from *crena*, a notch). CRENATED. When the edge of a leaf is cut into angular teeth, it is called acutely crenated; when into segments of small circles, instead of angular teeth, it is said to be obtusely crenate; when the larger segments have smaller ones upon them, the leaf is then said to be doubly crenate: the same term is applied to the corolla and nectarium in some cases.

CREPA'TIO, and CREPATU'RA, (from *crepo*, to make a noise). In pharmacy is the cracking or bursting of any seed in boiling or roasting, and this is to be understood when seeds are directed to be boiled *ad crepaturam*. See also HERNIA SCROTALIS.

CREPI'NUM. See TARTARUM.

CRE'PITA Æ'TAS. See ÆTAS.

CREPITA'TIO. See DECREPITATIO.

CRE'PITUS, (from *crepo*, to make a noise). Cracking of the joints, which may happen either from a defect of synovia, or a deposition of cretaceous matter, as in the gout; but is generally owing to the former cause. Mr. Sharp recommends a frequent use of fomentations, rubbing the joint with the ungt. hydrargyri, and to administer purges occasionally.

It means also a discharge of air from the anus when attended with a noise.

CRE'PITUS LU'PI. See LYCOPERDON VULGARE.

CRESPI'NUS, (quasi *crispinus*, from *crispus*, curled, crisped; so called from the crispness of its leaves and wood.) See BERBERIS.

CRE'SPULUM, (from *crispus*, crisp; from the crispness and curledness of its leaves). See BUPHTHALMUM.

CRE'SSIO, (from *cresco*, to grow; because of their abundance every where). See NASTURTIIUM AQUATICUM.

CRE'TA, (from *Crete*, the place whence it was first brought). CHALK. The only kind now used in medicine is the white chalk, which is found in most parts of the world. It is a pure white mineral calcareous earth of different degrees of hardness; it crumbles between the fingers, and stains them white; readily diffuses in water when finely powdered, and as soon subsides; sticks to the tongue without any astringency. Its form is amorphous, stalactitical, or crystallized; specific gravity from 2.3 to 2.7. Its crystals are rhomboidal paral-

leloped, and when transparent their refraction is double.

The best is that which is perfectly white, soft, close, and solid, equal and uniform when broken, free from sand and flints, and insipid to the taste; though chalk, when first dug, has often a slight pungency, as it has not a full proportion of carbonic acid. Many other earths are of a similar nature, but this being the purest is preferred.

It dissolves in all the acids, particularly in the nitrous and muriatic; even totally in vinegar. The vitriolic precipitates it from all other acids, and forms with it a selenite. It is convertible into quick lime: with borax it melts into a transparent glass. The solutions of it in acids are bitterish.

Chalk is employed as a remedy against the heart burn, and other disorders that have acidity in the primæ viæ for their cause. Some use it, when finely powdered, to sprinkle on erysipelatous inflammations. Two drachms for a dose, and repeated at proper intervals, have often effected, it is said, a speedy cure both in a diarrhœa and a dysentery; but this effect, if true, must be owing to its absorbing those acids whose stimuli caused the morbid excretion. When milk turns sour on the stomach, a scruple of chalk may be given with each half pint. This, however, is a very uncommon effect; but chalk is also added when milk forms a hard coagulum, and lies heavy on the stomach. When on any account a free use of chalk is required, if the belly is inclined to costiveness, laxative medicines should occasionally be taken, as the earth may otherwise accumulate.

Chalk should be finely powdered, and separated from its grosser parts by elutriation. Boerhaave prefers it to the cornu cervi calcinatum for making the white decoction with. Bates formerly used to boil half a pound of chalk in three pints of water to a quart, after which he just permitted the grosser parts to fall, and poured off the yet turbid fluid for use; and the London college directs the following chalk mixture, formerly called *julepum è creta*: take of the whitest chalk prepared, one ounce; of double refined sugar, six drachms; of gum arabic, finely powdered, two ounces; of distilled water, a quart: mix. Pharm. Lond. 1788.

See Dale. Lewis's Mat. Med. Dict. of Chem. Neumann's Chem. Works. Cullen's Mat. Med.

Besides these, the following are often used:

*Compound ointment of chalk: neutral cerate of Kirkland.*—R. Cretæ pp. aceti distillati, olei olivæ aa  $\frac{3}{4}$  iv. emplastri lithargyri  $\frac{3}{4}$  8. aq. lithargyri acetati  $\frac{3}{4}$  ss. The chalk and vinegar are to be mixed together, and over a slow fire, incorporated with the litharge plaster, and oil; when sufficiently united, the water of acetated litharge is to be added. This is allowed to be an efficacious remedy, when applied to inflamed parts and ulcers, and is much employed in practice. Chalk is often applied to ulcers in its dry state, when the discharge is thin and acrimonious, with success; and it is sprinkled on the poultices in burns, according to Mr. Cleghorn's plan, with singular advantage.

We find in some foreign authors an *acetat* and a *citrat of lime* recommended in scrofula, pruritus, hernia, humoralis, tumours of the mesenteric glands, in a dose of one or two ounces daily. In this kingdom, the muriat of lime formed by saturating common muriatic acid with chalk, is recommended in scrofula and obstructed

glands; of which from half a drachm to half an ounce, in a pint of water, is to be taken daily.

*Decoctum è creta.* (See CORNU CERVI.) *Pulvis è creta compositus; pulvis è creta comp. cum opio.* See BOLUS.

The two last supply the place of the pulvis è bolo compositus, a pulvis è bolo compositus cum opio, of the old London Pharmacopœia.

CRE'TA NIGRA. BLACK CHALK, called also *humus nigra pictoria*; has never been employed in medicine.

CRE'TA RU'BRA. See OCHRA.

CRE'TA SELENSIA, called also *terra selenusia*. The best is of a shining white friable appearance, and readily diluted with a fluid. It is drying and astringent.

CRE'TA CIMOLIA. TOBACCO PIPE CLAY. And *creta fullonica*. FULLER'S EARTH. See CIMOLIA ALBA.

CRETA'CEUM A'CIDUM, (from *creta*, chalk). THE CARBONIC ACID.

CRE'THMON. (Greek.) See CRITHMUM.

CRE'VIS. See ASTACUS FLUVIATILIS.

CRIBRA'TIO, (from *cribrum*, a sieve). SEARSING. In pharmacy, it is the passing of powders and pulps through a sieve, or searse.

CRIBRIFO'RME, and CRIBRO'SUM OS, (from *cribrum*, sieve). See ETHMOIDES OS.

CRICELA'SIA. The driving a hoop as high as the breast of the person who used it was formerly commended for rendering the limbs pliable, and strengthening the nerves. It was an ancient gymnastic exercise.

CRICO-ARYTÆNOIDÆI MUSCULI, (from *κρικος*, a ring, *αρυταινα*, a funnel, and *ειδος*, forma). Muscles of the larynx, whose office is to open the glottis. They arise from the cricoid cartilage, and are inserted into the arytenoid.

CRICO ARYTÆNOI'DES LATERA'LES. They lie laterally upon the upper edge of the cricoid cartilage, and are inserted into the lower part of the side of the arytenoid. They serve to dilate the glottis.

CRICO ARYTÆNOI'DES PO'STICI. They lie upon the back part of the cricoid cartilage, and are inserted into that knob which stands on the back part of the basis of the arytenoid cartilage, near the angle of the basis, one on each side. They open the larynx, and are called, by Casserius, *har-cucullare*.

CRICO PHARYNGÆI. These muscles arise from the lower part of the side of the cricoid cartilage. They seem to be appendices of the *thyro-pharyngæi*, showing no other marks of distinction but their insertions, and a small difference in direction, because as they run backward they descend a little; for this reason, Winslow says he hath sometimes looked on them as one, and calls them *thyrocrico-pharyngæi*. The lowest of these muscular fibres, he says, makes a complete circle backwards, between the two sides of the basis of the cartilago cricoides, which is the beginning of the œsophagus, and has been sometimes supposed to form a distinct muscle, called *œsophagus*. There is another fasciculus of fibres occasionally detached from the thyro-pharyngæus, and inserted laterally in the thyroid gland, for which reason I call it *musculus thyro-adenoidæus*. Innes calls it the *constrictor pharyngis inferior*; and describes it as follows. It arises from the side of the thyroid cartilage, near the attachment of the sternohyoidæus and thyro-hyoidæus muscle, and from the

cricoid cartilage, near the crico-thyrodæus. This muscle is the largest of the three, and is inserted into the white line, where it joins with its fellow; the superior fibres running obliquely upwards, covering nearly one half of the middle constrictor, and terminating in a point; the inferior fibres run more transversely, and cover the beginning of the œsophagus. Their use is to compress that part of the pharynx which they cover, and to raise it with the larynx a little upwards. See PHARYNX.

CRICO THYROIDÆI. Certain muscles of the larynx, which shut up the glottis. They rise from the anterior and lateral part of the cricoid, and are inserted into the lower edge of the thyroid cartilage. These are sometimes called *crico-thyroidæi antici*.

CRICOIDES, or CYMBOLA'RIS CARTILA'GO, (from *κρινος*, a ring, and *ειδος*, a form). The name of the annular cartilage belonging to the larynx, which it encompasses. See ASPERA ARTERIA.

CRICOS, (from *κρινος*, a ring, or circle). The annular cartilages, which form the aspera arteria. Hippocrates.

CRIDO'NES. See CRINONES.

CRIMNO'DES, (from *κρινων*, bran). An epithet for urine, which deposits a branny sediment.

CRIMNO'N. (Greek.) Dioscorides describes it as a coarse sort of meal produced from maize and wheat, of which they make pulse; Galen, as the largest particles of torrefied barley, which have escaped due contusion in the mill.

CRINA'TUM, (from *κρινον*, a lily). An epithet of suffumigation, mentioned in P. Ægineta; composed chiefly of the roots of lilies.

CRINEDO'NES, and CRINES, (from *crinis*, hair). See CAPILLARES VERMICULI.

CRINI'S. See CAPILLUS.

CRINI'TUS, (from the same). HAIRY, or HAVING LONG HAIR, or BEARDS RESEMBLING HAIR. In botany it means abounding with capillaments or small fibres like hairs, as in the root of the leek; and the phleum crinitum.

CRINOMY'RON, (from *κρινον*, lily, and *μυρον*, an ointment). OINTMENT OF LILIES, consisting of lilies and some other aromatics. It was also called *Ægyptium album*, and *susinum*.

CRINO'NES, (from *crinis*, hair,) called also *comedones*, *cridones*. "The mention of dracunculi," observes Ambrose Paré, "calls to my memory another kind of abscess, altogether as rare. This our Frenchmen name *crinones*, I think, à *crinibus*, i. e. from hairs. It chiefly troubles children, and pricks their backs like thorns. They toss up and down, being not able to take any rest. This disease arises from small hairs, which are scarce of a pin's length, but thick and strong. It is cured with a fomentation of water more than warm; after which you must presently apply an ointment made of honey and wheaten flour: for so these hairs, lying under the skin, are allured and drawn forth; and being thus drawn, they must be plucked out with small mullets." See Edinb. Med. Comment. vol. ix. p. 64.

In the History of the Royal Medical Society at Paris, for the year 1776, Mons. Bassignet observes, that this disease, said to be peculiar to the town of Seyne and its neighbourhood, attacks almost all the new born children. In the place itself it is called *cées*, a corruption of *ceddés*, a provincial word that signifies a *bristle*. It appears in many cases within twelve hours, in others not till a

month after birth; and sometimes, though rarely, at a more advanced age. The symptoms are described to be a violent itching, increased by the heat of the bed, and preventing sleep; a diminution of the voice; continual agitation; incapability of sucking, the child's tongue not being able to accommodate itself to the nipple; a hoarseness, and gradual extinction of the voice. Of all these symptoms, the last is considered as the most certain; so that by the weakness of the child's cries, and the alteration in its voice, the degree of the disorder is judged of. As soon as it is observed, they employ frictions; and the women of the country are so accustomed to this disease, that they seldom call in either a physician or a surgeon. These frictions are made on different parts of the body, according to the three states of the disease, which are sometimes distinct, at others complicated. In the first, to a diminution of voice is joined an inability to suck. This, we are told, requires frictions at the upper part of the sternum, neck, cheeks, and about the jaws and temples. If the child, though its tongue be at liberty, is still unable to seize the nipple, and his arms or fingers at the same time tense, this is the second state of the disease, and requires frictions on the fore arm. The third is known only by the change in the voice, and is cured by rubbing the arms, shoulders, back, and calves of the legs. In this mode of friction the woman wets her hand with saliva, and rubs the skin of one of the child's arms, for instance, along the tensor muscles, till she feels a considerable roughness. She then quits this arm, and begins with the other; rubbing always in small circles, and constantly in the same direction. Nothing particular is observed in the skin previous to these frictions, though some of the most experienced women speak of a tension which yields to rubbing. In many cases where this practice hath been neglected, the child, it is said, has been carried off by convulsions or diarrhœa. In some subjects a species of dark rough hairs, not longer than the tenth of an inch, and in others little substances resembling very fine red hair, not quite so rough as the former, and furnished with a minute bulb, at their extremity, appear on the skin, and terminate the disease. This circumstance gives a name to the complaint. A case is related of a girl ten years old, who, after having been for some time ill, and taking different medicines, at length tried the frictions above described, which brought out a prodigious quantity of dark coloured rough hairs, after which she recovered.

Lorry de Morbis Cutaneis. The London Medical Journal, vol. ii. p. 289. See BOVINA AFFECTIO.

CRIO'GENES. An epithet for certain troches mentioned by Paulus Ægineta, and which he commends for cleansing sordid ulcers.

CRIO'MY'XUS, (from *κριος*, a ram, and *μυξα*, mucus; because it frequently affects sheep). An epithet for persons abounding with mucus in the nose.

CRISO'RCHIS, (from *κρυπνω*, to hide, and *ορχις*, a testicle). See TESTES and PARORCHIDIUM.

CRISIMOS, (from *κρινω*, judico, to judge). CRITICAL.

CRISIS, (from *κρινω*, to judge). The termination or change of a disease either by recovery or death.

Hippocrates first established the doctrine of crises and critical days, which were, the 3d, 5th, 7th, 9th, 11th, 14th, 17th, and 21st. Fevers were probably more regular in their periods at this time, because they were seldom interrupted in their progress by medicine. A

crisis only respects acute diseases, and more particularly continual fevers. At this time, critical days are not a subject of frequent attention; the type of the disorder being changed, and the crisis accelerated or retarded, by what is administered.

Asclepiades and Celsus deny that diseases have their critical days; and Langius adds, "if a crisis is to be expected, medicine is superfluous."

The coincidence of critical days with the Pythagorean numbers, has induced many physicians to oppose the doctrine as fanciful, or to reject it as false. Others have as strenuously contended for the reality of changes generally salutary on particular days, rather than on others; and those particular days are the same which we have already mentioned.

There is little doubt of the universality of the tertian period. It has been proved by numerous facts, with great logical precision, by Stahl, in a separate dissertation. We generally find also a fever formed, not on the day following the action of the exciting cause, but on the alternate day. If the fever consists only of one paroxysm, the 3d or 5th will be salutary; if of two, the 7th. We thus find the first septenary period very clearly established. The 14th is generally acknowledged as a critical day; but the days of the interval are not so clearly established. The 11th is not strikingly critical; but if the patient pass the 10th in safety, and the treatment be properly regulated, the disease generally terminates on the 14th. If in the evening of the 14th there is a violent fresh exacerbation, it is highly dangerous; yet a slight exacerbation is, in part, removed on the 17th, and completely on the 20th or 21st.

It will be obvious, that in the first fourteen days the crises observe the tertian period; afterwards the quartan; but the reason is uncertain, except that the constitution, accustomed to the action of the cause, is not so readily affected by it; for the more violent the cause, the shorter and the more violent are the periods, and the disease. In fact, we have been generally able, in this climate, to trace changes generally salutary on the days styled critical; and, if the practice is well conducted, they may be observed in almost every continued fever, though not in all equally striking.

De Haen, who acknowledges the influence of particular days, has taken the trouble of selecting the facts from the most approved works of Hippocrates; and of 163 instances of the termination of fever within the first twenty days, more than two-thirds, viz. 107, happened on the days mentioned as critical. None happened on the 2d or 13th; and upon the 8th, 10th, 12th, 15th, 16th, 18th, and 19th, there are but eighteen instances of termination. As, from the preceding facts, regular periods in fevers are sufficiently obvious, so from these the real periods appear to be those stated in the commencement of the article. De Haen *Ratio Medendi*, vol. i. p. 19.

The word crisis, however, is not confined to this signification; for sometimes it means the excretion of something noxious from the body, or of the noxious fluids in a fever; for the word *κρίσις* signifies also to separate, or as it were to pass through a sieve.

Those who observe critical days consider crudity as that state of the morbid matter wherein it is unfit for a regular separation from the sounder juices; concoction, as that change in the morbid matter, by the power of

nature, or assistance of art, which renders it fit for separation from the healthy part of our fluids; crisis is, therefore, the actual discharge of the morbid matter, whether brought on by the power of nature, or by medical aid; and the critical day is the time that this discharge happens. See FEBRIS.

On this subject see Hippocrates, Galen, P. Ægineta, Fernelius, De Haen, and Cullen; on the other side, Asclepiades, Celsus, Langius, Faber, and a tribe of moderns.

CRISPATU'RA, (from *crispio*, to turn, or curl). CRISPATURE, CURLING. In medicine it is supposed to be a spasmodic contraction or curling of the membranes and fibres; but these are not muscular, and we have no evidence of contraction except in muscular fibres. The idea arose from the sensation, referred to membranes; but really arising from an affection of some neighbouring muscles.

CRISPI'NUS, (from *crispus*, turned or curled). See BERBERIS.

CRISTA, (quasi *cerista*, from *κερος*, a horn; or *carista*, from *καπα*, the head; as being on the top of the head). Any thing which has the appearance of a crest or comb, as on the head of a cock. Tubercles near the anus and pudenda are so called on account of their form. The cause and cure are the same as of the condyloma. See PROCESSUS.

CRISTA GA'LLI. In anatomy, it is an eminence rising from the upper part of the os ethmoides, to which the beginning of the falciform process is attached. It is called *crista galli*, from its supposed resemblance to the comb of a cock. See ETHMOIDES OS.

CRISTA PAVO'NIS. See POINCIANA FLORE PULCHERRIMO.

CRISTA PAVO'NIS CORONI'LLÆ FO'LIO. See BRASILIUM LIGNUM.

CRISTÆ CLITO'RIDIS. See NYMPHÆ.

CRISTA'TUS, (from *crista*, a cock's comb, crested,) is a term in botany, and means having a tuft upon the top.

CRITHAMUM. See CRITHMUM.

CRITHE. (Greek.) BARLEY; and, from its similitude, a sort of tubercle on the eyelid is thus named; called also a *stye*; and by Ætius, *grando*. It is a hard scirrhous immovable stian in the interior part of the eyelid, containing a pellucid body. When small it is seated on the edge of the eyelid, but when large it spreads further. When the stians do not suppurate, they become wens; and are apt to disappear and return. If there be inflammation, the white bread poultice may be applied to promote suppuration: if it is hard, a mixture of equal parts of hog's lard and quicksilver will destroy it. If the lower eyelid is affected, the tumour is more frequent on its inside: it may then be dissected; and a caustic should be applied on the skin just upon it, to make an external opening for it. See St. Yves on Disorders of the Eyes; also HORDEOLUM and CHALAZA.

CRITHMUM, (from *κρίνω*, to secrete; so named from its supposed virtues in promoting urine and the menses). Called also *feniculum marinum majus* and *minus*, *herba Sancti Petri*, *hashtier*, *baticula*, *crithamum*, *crithrum marinum*; SAMPIRE and SAMPHIRE.

It grows wild on rocks, and in maritime places: the leaves resemble those of fennel, but the segments are

thicker and shorter; to the taste they are warm and bitter, to the smell somewhat like smallage. They are aperient and diuretic; but chiefly used as a pickle.

**CRI'TICA SI'GNA**, (from κρίνω, *to judge*). Those signs which are taken from the crisis of a disease, respecting recovery or death.

**CRI'TICI**, (from the same). **CRITICAL FEVERS**. Those which terminate with a lateritious sediment in the urine.

**CRI'TICI DIES**, (from the same,) called *internuncii*. **CRITICAL DAYS**. See **CRISIS**.

**CROCI'DE CONFE'CTIO**. The name of a confection commended by Nicolaus Myrepsus for the colic.

**CROCI'NUM**, (from κροκος, *crocus, saffron*). **OIL OF SAFFRON**. It is mentioned by Dioscorides as consisting of olive oil, myrrh, and a small quantity of saffron.

**CROCO'DES**. An epithet for certain troches in P. Ægineta, from the saffron they contain.

**CROCODI'LION**, (from κροκοδειλος, *the crocodile*; from its deceit, in consequence of its change of colour). See **CARLINA**, **ERYNGIUM**, **ECHINOPUS MAJOR**.

**CROCODI'LUS TERRES'TRIS**. See **SCINCUS**.

**CROCOMA'GMA**, and **ECMAGMA** (from κροκος, *crocus*, and μαγμα, *thick oil*). Dioscorides informs us, that it is prepared of the ungt. crocinum, and spices pressed and made into troches.

**CRO'CUS**, (from *krokin*, Chaldean) **SAFFRON**: because of its golden colour, the chemists call it *aroma philosophorum*, by contraction *aroph*; others have called it *sanguis Herculis*, *aurum vegetabile*, *animum pulmonum*, and *Jovis flos*. For its supposed efficacy in some diseases, it is entitled *rex vegetabilium*, and *panacea vegetabilis*; from its power of exciting laughter, it hath the appellation of *hortus lætitiæ*; and from its cheering effects, *medicina tristiitiæ*. Besides these, various other names are to be met with in different authors. Its name of *saffron* is from the Arabian word *zaffaran*, or *zahafaran*. *Crocus sativus* α Lin. Sp. Pl. 50. Nat. order *liliaceæ*.

Saffron is a bulbous rooted plant; its leaves are shaped like those of grass; the flower is of a purplish blue colour, cut deep into six segments; in the middle of the flower, among the stamina, arises a pistil, which is divided at the top into three fleshy filaments; the upper part of these filaments is of a deep orange red colour, and the saffron of the shops. The plant is perennial; the flowers blow in September and October.

The filaments of the saffron flowers are carefully separated, and moderately dried in a kiln; and when no farther manufactured, are sold under the name, saffron in the hay. But the greatest part of this article is, after being dried to a certain degree, pressed into thin cakes.

It is cultivated in France, Spain, Austria, Hungary, &c.; but the best is produced in England, and the plant is now indisputably ascertained to be a native of this country. It may be distinguished from all others by the greater breadth of its blades. The best saffron is in long broad filaments, of a deep red colour, without any yellow parts, moderately dry, yet flexible and soft to the touch, difficultly pulverized, of a strong and agreeable smell, especially at a distance; affecting the eyes so as to draw tears from them; of a pungent and somewhat bitterish taste: it readily impregnates the hand with its

smell; stains the moist hand with a deep yellow colour, and colours a very large proportion of alcohol.

It is sometimes adulterated with the fibres of smoked beef, the flowers of the carthamus, the calendula officinalis, &c; but the imposition may be detected by the want of the white ends observable in saffron; the inconsiderable or bad smell, when thrown on live coals. The Spanish saffron is covered with oil, to preserve it. Of the foreign, the French and Austrian saffron is the best.

It yields in distillation with water a small proportion of essential oil, of a golden colour, heavier than water, with a smell of the saffron in a high degree. By other experiments it afforded the extractive copiously, and in a pure state. Its aromatic part is extremely volatile, so that it should be kept carefully covered. It yields its colour and virtue to spirit of different strengths; to wine, water, either cold or hot, and vinegar. The last soon loses its colour. The watery infusion and the vinous tincture soon grow sour, and lose all their colour and virtue. About three parts in four of the saffron are dissolved by each, and the remainder is a pale mass, without colour, taste, or smell.

As a medicine, it has been esteemed an agreeable aromatic, an anodyne, antispasmodic, cordial, and attenuant. Boerhaave ranks it among narcotic poisons; and, in case of an imprudent dose, orders a vomit and acidulated draughts. It has been called a very powerful emmenagogue, and said to require caution in its use, as some patients are more affected by it than others; in disorders of the lungs it hath been so esteemed as to obtain the name of *anima pulmonum*. In coughs it is highly commended; and Camerarius says, that a scruple of saffron, with half a grain of musk, is of considerable efficacy in asthmas. Very frequent experiments in practice do not, however, support the opinions commonly entertained of it. Dr. Cullen has given it in large doses, when it scarcely produced sensible effects in any degree, or increased the frequency of the pulse; and as anodyne or antispasmodic, he scarcely observed its operation. In one or two instances he suspected an emmenagogue power, but in others, though repeatedly employed in large doses, it was useless; and though he has given it in every shape, and in larger doses than authors ever proposed, he never discovered in it any virtue. Indeed, though the sensible qualities of this medicine are pretty considerable, it appears to possess no other power than that of a weak aromatic. In this medicine very little confidence is at present placed; though it enters into several officinal compositions, more on account of its colour perhaps than its utility.

In distillation, water is strongly impregnated with its flavour; and if the quantity of saffron is large, a small portion of a fragrant and very pungent essential oil may be collected, which, according to Vogel, amounts to about a drachm and a half from sixteen ounces. The remaining decoction, inspissated to an extract, retains all the virtues of the saffron, except, it is said, the cordial one. The spirituous extract retains much of the cordial quality, if it has any.

The dearth of saffron subjects it to many artifices; but the best method of avoiding them is to purchase only the sort called *hay-saffron*.

The London college directs the following method of preparing the **SYRUP OF SAFFRON**:

Take of saffron, one ounce; boiling distilled water, two pints; macerate the saffron with the water for two hours in a vessel close stopped; and to the strained liquor add, of double refined sugar, sufficient to make a syrup. Pharm. Lond. 1788.

See Lewis's Mat. Med. Raii Historia Plantarum. Neumann's Chemical Works. Cullen's Mat. Med.

CRO'CUS ANTIMO'NI. See ANTIMONIUM.

CRO'CUS I'NDICUS. See CURCUMA.

CRO'CUS MA'RTIS APERIENS, and ASTRINGENS. See FERRUM.

CRO'CUS METALLO'RUM. See ANTIMONIUM.

CRO'CUS SARACE'NICUS. BASTARD SAFFRON. See CARTHAMUS.

CRO'MMYON, or CRO'MYON; *παρα το τας κορας μνειν*, because it makes the eyes wink. AN ONION. See CΕΡΑ.

CROMMYOXYRE'GMIA, (from *κρομμυον*, an onion, *οξυς*, acid, and *φυγειν*, to break out). Acid and fetid eruptions, resembling the taste of onions.

CRO'TAPHI, (from *κροτω*, to beat, from the pulsation always perceptible there). See TEMPORA.

CROTAPHI'TES, (from *κροταφον*, the temple, or *κροτω*, to beat, as the pulse). See TEMPORALIS MUSCULI.

CROTA'PHIUM, (from *κροταφο*, the temples). A pain in the head near the temples.

CRO'TAPHOS, (from *κροταφω*, to beat). See CEPHALALGIA.

CRO'TON. According to Fœsius, it signifies, in Hippocrates, the bronchiæ of the lungs expectorated; a name also of the seeds from whence the ol. ricini is taken. See CATAPUTIA.

CRO'TON BENZO'E. See BENZOINUM.

CRO'TON CASCARI'LLA. See THURIS CORTEX.

CROTO'NE, (from *κροτων*, the tick). A fungous excrescence on trees, produced by an insect like the tick; but applied to excrescences and fungous tumours on the periosteum.

CROU'SMATA. This word is met with in Myrepsus, and is translated by defluxions, rheums: but Fuchsius thinks it should be read *ρευματα*.

CRUCIA'LIA, LIGAME'NTA, (from *crux*, a cross). They rise from the inside of each condyle, and are attached to the femur. They give strength to the joint, and limit its motion.

CRUCIA'LIS INCI'SIO, (from the same). An incision in the form of a cross.

CRUCIA'LIS GA'LLI SPECIES. See CRUCIATA VULGARIS.

CRUCIA'TA, (from *crux*, a cross). CROSS WORT, from its leaves being disposed in the form of a cross. The only species is the c. vulgaris, called *valantia aparine* Lin. Sp. Pl. 1491, also *cruciata hirsuta*, *crucialis gallii* species, *gallium latifolium flore luteo*, MUG WEED and CROSS WORT.

The roots are slender and creeping, the branches hairy, about a foot high; at the joints of the stalk are placed four round pointed leaves that are hairy, and have foot stalks; the flowers are small and yellow, each followed by two small round black seeds. It grows in hedges and the sides of fields, and flowers in July. The leaves and tops are commended for promoting expectoration. Raii Hist.

CRUCI'BULUM, (from *crucio*, to torment). Also called *tigillum*, *catinus fusorius*, *albot*, *alkozoal*, or *crucible*.

VOI. I.

It is an earthen vessel, made for enduring the greatest degree of heat, generally wider above than below, and of a round or triangular figure. Calcined bones are equal, if not superior, to any other materials for making them; some are made of equal parts of the best potter's clay dried, of a plumose alum, and of bastard talc, finely powdered, formed into a paste with whey, and then baked as other pottery. Chalk cut into the form of a crucible, then steeped in linseed oil for twenty-four hours, answers many purposes very well: some use the powder of common tiles, and an equal quantity of chalk: these are mixed with linseed oil, and then baked. They may be either made of earth, black lead, forged iron, or platina; Chaptal says, they ought to support the strongest heat without melting, and be capable of resisting the attacks of all such agents as are exposed to heat in vessels of this kind. Those crucibles which possess the greatest degree of perfection are made in Hesse, or Holland. Those made of platina unite the most excellent properties. They are nearly infusible, and at the same time indestructible by fire. M. Achard, and M. Morveau, have made them by first fusing platina with arsenic, which at first remains brittle; but in proportion as the arsenic is driven off by the continuance of heat, it becomes more ductile. These chemists, by melting it a second time in moulds, formed crucibles. Platina has been lately found more manageable, and various chemical vessels of this metal are now commonly met with. Various other materials, and modes of combining them, may be seen in Pott's Dissertation on Crucibles, and in the Dictionary of Chemistry. Chaptal's and Lavoisier's Elements of Chemistry.

CRUCIFO'RMIS, (from *crux*, a cross). Shaped like a cross; a botanical term, expressing the shape of flowers in a particular state.

CRU'DITAS, (from *crudus*, raw). CRUDITY. It is applied to unripe fruits, raw flesh, undigested substances, humours in the body in a state unprepared for expulsion, and to the excrements. See CRISIS.

CRU'DUS, (from *κρυος*, cold, i. e. raw). Crude, undigested, unconcocted.

"Crudum, pavonem in balnea portas." JUVENAL.

CRUE'NTA SUTU'RA, (from *cruor*, blood). BLOODY SUTURE; when the lips of a wound are brought together by means of a ligature made with a curved needle.

CRU'NION, (from *κρουνος*, a torrent; from the violence of its operation). The name of a diuretic compound medicine described by Ætius.

CRU'OR. BLOOD EXTRAVASATED AND CONGEALED, (from *κρυος*, cold). Sometimes it means the blood in general, and occasionally the venal only.

CRUPI'NA. See CALCITRAPA.

CRU'RA CLITO'RIDIS, (from *crura*, legs). See CLITORIS.

CRU'RA MEDU'LLÆ OBLONGA'TÆ. The two largest legs, or roots, of the medulla oblongata, which proceed from the cerebrum. See CEREBRUM.

CRURÆ'US, CRURE'US, or CRURA'LIS, (from *crus*, a leg). The crureus, the vastus externus, and vastus internus, may be considered as one muscle. (See VASTUS INTERNUS). The crureus muscle covers almost all the fore side of the os femoris, between the two vasti. The tendons of the crureus rectus anterior, and of the two vasti, unite into one, and are inserted into the side of the patella, in the edge of the ligamentum

of that bone, and in the adjacent lateral part of the head of the tibia. They extend the leg.

CRURA'LES ARTÉ'RIÆ, (from *crus*, a leg). The CRURAL ARTERIES.

The external iliac arteries pass out of the belly under the inguinal glands, and there take the name of *crural*: they run over the heads of each os femoris, turn under the crural vein, presently after passing out of the abdomen; here they are not covered with any muscles, but presently plunge betwixt the sartorius, vastus internus, and triceps muscles, and are covered by them all the way to the lower part of the thigh. A little above the internal condyle of the os femoris, they perforate the tendon of the triceps, and run to the posterior part of the thigh, down the ham, and there take the name of *popliteæ*. In the course of these arterics, they give out the pudicæ externæ, and other branches, to the different muscles of the thigh.

CRURA'LIS NÉ'RVUS, (from *crus*, a leg). The nerve which passes from the loin into the thigh is thus called. The second lumbar nerve joins the third, and that again communicating with the fourth, they produce this crural nerve (see LUMBARES,) which passing under Poupart's ligament, runs on the fore part of the thigh, under the iliacus internus muscle; it disperses itself into many branches, one of the principal of which accompanies the vena saphena all the way to the ancle.

CRURA'LIS VENA, (from the same). Called also *ischias*. The external iliac vein, going out from under the ligamentum Fallopii, on the inside of the iliac artery, is there called *crural*. About an inch below its passing out of the abdomen, it sends off a large branch, called the *saphena*; after which it sinks between the muscles, and is distributed to all the inner parts of the lower extremity, accompanying the crural artery to the toes. In its descent down the thigh, it runs behind the crural artery: when it hath arrived into the lower part of the thigh, its situation is between the crural artery and the inner condyle of the os femoris; and just above the ham it takes the name of *poplitea*.

CRUS, (a *currendo*, from *running*, or rather from the Hebrew term *crugh*, to bend, as the knee). The LEG. It includes the whole of the lower extremities, from the os innominatum to the toes; viz. the thigh, leg, and foot. It sometimes signifies only the thigh, and is occasionally confined to that part between the knee and ancle.

CRU'STA, (from the Hebrew term *chresh*). The shell of a lobster, crab, cray fish, prawn, or shrimp; also the name of a scab, scurf, or eschar, upon a diseased part: sometimes a crust or cream which coagulates on the superficies of any liquor, as on blood and urine, or upon fermentable liquors during one stage of their fermentation.

CRU'STA LA'CTEA. See ACHOR.

CRUSTA'CEA, (from *crusta*, a shell, and *μακροστρακα*), are animals which have the external parts firm and hard, but contain a fleshy soft substance within. The firm part consists of a semicalcareous crust, forming one very large and several small pieces, or a series of rings nearly equal. They have their heads furnished with horns and other appendages; numerous feet obliquely bent and articulated; two arms called *clavus*, notched like a forceps, and breathe by means of distinct gills. Ancient naturalists united them with fish, or

in a separate class after fish, or after the molluscæ. Pliny comprehends all crustaceous animals under the name of *crabs*. Linnæus classes them among insects without wings, under the generical name of *crabs*. Since the time of the Swedish naturalist they have been arranged with insects, though their structure is very different, since they breathe by gills, and have a muscular heart. Cuvier and La Marck have agreed, therefore, in separating them from insects. The former places them as a distinct class between worms and insects; the latter between the molluscæ and arachnides, a class formed by him to connect the crustaceæ with insects. They differ, therefore, from fish and molluscæ in having articulated limbs; and from insects by having a muscular heart, and breathing by gills.

Dr. Cullen takes notice in general of the lobster, crab, prawn, and shrimp only; of which he says the two former hardly differ in any quality from one another: and from the small proportion of volatile alkali that is obtained from their entire substance, or extract, he concludes they contain less animal matter than the flesh of quadrupeds, birds, or even the amphibia. They appear to be more easy of digestion than animal food, or aliment of any other kind. See ALIMENT.

CRU'STULA, (from *crusta*, a shell). See ECCHY-MOSIS.

CRUSTU'MINA PYRA, (from *Crustuminum*, a town, where they grow). PEARS much admired by the Romans, and mentioned by Columella, v. 10. Rhodius thinks it the bergamot pear; but from its history this is not probable: it seems to resemble the Catharine pear.

CRUSTUMINA'TUM, (from the same). A sort of rob made of the juice of apples and pears, boiled with honey and rain water. Ætius gives directions for the preparation.

CRUX-CE'RVÍ, (from *cruz*, a cross, and *cervus*, a stag). See CERVUS.

CRYMO'DES, (from *κρυος*, cold). An epithet for a fever wherein the external parts are cold.

CRYO'XA. Erotian thinks it a kind of pot herb.

CRY'PTÆ, (from *κρυπῶ*, to hide). Hollow cavities, containing some fluid. See FOLLICULUS.

CRYPTOGA'MIA (from *κρυπτος* and *γάμος*, concealed nuptials). The twenty-fourth of Linnæus's classes of plants; denominated from the obscurity of their manner of impregnation. They comprehend vegetables whose fructification is concealed, or at least too minute to be observed by the naked eye. The mosses, mushrooms, flags, and ferns, are of this class. In the fern, the seeds are found on the back of the leaves of the plant.

CRYPTOPYICA. ISCHURIA. A suppression of urine, from a retraction of the penis within the body. See ISCHURIA.

CRYP'SORCHIS, (from *κρυπῶ*, to hide, and *ορχος*, testis). A retraction, or retrocession, of one of the testicles.

CRYSTA'LLI, (from *κρυος*, cold, and *στέλλω*, to contract; for crystals were considered as water contracted by cold). See CRYSTALLINÆ.

CRYSTA'LLI TA'RTARI. See TARTARUM.

CRYSTALLI'NA. The CRYSTALLINE HUMOUR OF THE EYE, (from *κρυος*, cold, and *στέλλω*, to contract). Called also *crystallinus humor*; and *discoides*, from its resembling a disk or quoit of the Romans.

Immediately behind the aqueous humour is situated

the crystalline; transparent, of the colour of crystal. It is situated between the aqueous and vitreous humours, its anterior part being opposite to, and very near the pupil; its posterior part is lodged in a cavity, formed for its reception in the middle and fore part of the vitreous humour: the figure of the crystalline is that of a lens, convex on both sides, but rather more so posteriorly. The crystalline is the least, but of the most firm consistence, of the three humours of the eye. It is more firm in the middle than in the sides; and, in time, is apt to change both in its consistence and colour, growing still more firm, and yellowish. It is invested with a dense, firm membrane, which is rather loosely connected to it; is perfectly transparent, but, when injected, appears furnished with numerous blood vessels. In the fœtus there appears a branch of the artery that passes through the axis of the optic nerve, which comes through the vitreous humour, and ramifies through the capsule of the crystalline in a radiated manner; this is much larger in the fœtus, and stronger than in adults: these branches go to the tips of the processus ciliaris, and are there imperceptible. The crystalline humour is membranous, and consists of many coats inclosed in one another; the whole of which are contained in a capsule, formed by a continuation of the covering of the vitreous humour. This capsule is called *ARANEA*; q. v. The crystalline produces a second refraction of the rays of light; the first refraction, which is produced by the cornea and the aqueous humour, not being sufficient to bring them to a focus at the retina. More minutely examined, its specific gravity was found by Mr. Chenevix to be 1100. When fresh it was neither acid nor alkaline, but putrified rapidly. It is almost wholly soluble in water, and is partly coagulated by heat. Tanin gives a copious precipitate; but when free from the other humours, no traces of the muriatic acid were found. The proportion of water is therefore smaller; those of albumen and gelatine larger than in the other humours. *Philosophical Trans.* 1803, p. 197.

**CRYSTALLINÆ**, (from the same). **CRYSTALLINES**. Also *crystalli*. The Italian physicians call them *varoli*. They are pustules filled with water, transparent, and on that account receive their name. They are sometimes about the size of a lupin, and appear over the whole body. But when they attend a gonorrhœa, they are considered as one of the most troublesome symptoms. They are lodged on the prepuce without pain; and, though caused by coition, are not infectious. The cause is supposed to be a contusion of the lymphatic vessels in the part affected. Dr. Cockburn, who hath described this case, recommends for the cure a mixture of three parts of lime water and two of rectified spirit of wine, to be used warm as a lotion, three times a day.

**CRYSTALLINÆ MĀNUS**. In Hippocrates, are hands so cold as to seem frozen.

**CRYSTALLINUM**, (from the same; so called from its transparency). See **ARSENICUM ALBUM**.

**CRYSTALLINUS HUMOR**, (from the same). See **CRYSTALLINA**.

**CRYSTALLION**. See **PSYLLIUM**.

**CRYSTALLISATIO**, (from *κρυστάλλος*, *crystal*). **CRYSTALLIZATION**. The parts of all bodies which take the solid state are disposed to arrange themselves in such a manner, as to produce some regular geometrical figure in the solid. This property is called *crystallization*, and the regularly figured bodies we call *crystals*. In this process the integrant parts of a solid body, separated from each other by the intervention of a fluid, exert the mutual attraction of aggregation, so as to coalesce and produce a solid mass.—When the particles of a body are only separated by caloric, and the substance is retained in the liquid state by its means, all that is necessary for its crystallization is, to remove a part of the caloric; in other words, to cool it. If this refrigeration be slow, and the body be at the same time left at rest, its particles assume a regular arrangement; and crystallization, properly so called, takes place: but if the refrigeration is rapid, or if the liquor be agitated at the moment of its passage to the concrete state, the crystallization is irregular and confused. The same phenomena occur in watery solutions, or rather in those made partly in water, and partly by caloric. So long as there remains a sufficiency of water and caloric to separate the particles of the body beyond the sphere of their mutual attraction, the salt remains in a fluid state; but when the necessary quantity of either is deficient, and the attraction of the particles for each other becomes superior to the power which separates them, the salt recovers its concrete form, and the crystals produced are more regular in proportion as the evaporation has been slower, and more tranquilly performed.

To dispose a substance to crystallization, it is necessary, in the first place, to reduce it to the most complete state of division. This may be effected either by solution, or by an operation merely mechanical. Solution may be effected either by the means of water or fire. The solution of salts is generally performed by means of the first; that of metals of the second. In order that the form of a crystal may be regular, three circumstances are required; *time*, *a sufficient space*, and *repose*. Sometimes the assistance of *light* is apparently requisite, though in general injurious to the regular formation of crystal. Time brings the integral parts by insensible gradation nearer each other, and without any sudden shock; so that they unite according to their constant laws, and form a regular crystal. Space, or sufficient room, is likewise a condition necessary for obtaining regular crystallization. If nature be restrained in her operations, the product of her labour will exhibit symptoms of constraint. A state of repose in the fluid is likewise necessary to obtain very regular forms: uninterrupted agitation opposes all symmetrical arrangement; and in this case the crystallization obtained will be confused and indeterminate.

This term, however, is most commonly applied to bodies of the saline kind; but not till lately applied to the freezing of water, or to the consolidation of metals after they have been melted. In every change, however, from a fluid to a solid state, we can perceive traces of this operation, if we, perhaps, except the fat oils. Though this is accounted one of the processes of chemistry, it is truly a process of nature, and may be discovered in all her operations. All the deliquescent salts are excluded from this operation, and the volatile ones never assume this form, unless their vapours are confined. Some of the neutral kind, particularly those of which certain metallic bodies are the basis, are as capable of crystallization, if a sufficient quantity of water be added, or any substance with which the water has a greater

affinity. Different salts also require different quantities of water to dissolve them; so that if a mixture of two salts be dissolved in one fluid, they will begin to separate at different times of the evaporation: upon this foundation salts are freed not only from their impurities, but also from one another; that which is least soluble shooting first.

The manner of crystallizing salts is, to make a saturated solution of them in boiling water; for hot water dissolves a larger quantity of many salts than it can suspend when cold. The solution must be then put into a proper vessel, and stand still in a cool place till the crystals are formed, which sometimes require several days. When crystals are formed, the remaining solution must be poured off, and what the crystals retain drained from them, by means of bibulous paper, then dried. There is a certain portion of the menstruum, which, though it contains salts, never permits them to crystallize. This arises from a viscosity or oiliness in the fluid, which prevents the mutual attraction of the saline particles; and in the salt works it is called *oil of salt*. Chemists style it the *mother water*; sometimes the *mothers*.

The cause of crystallization seems to depend on the attraction and repulsion with which the different portions of the molecule are endowed. Attraction alone will not explain the phenomena; and, indeed, with the assistance of its antagonising power, they are very obscure. The crystals are apparently formed with some momentum, and they are seen in their shooting to strike the glass forcibly. Vauquelin saw a thin glass broken by this means. Whatever be the variety of crystals, the primordial forms are few. Their forms have been explained with great precision by Haüy; and they appear so constant and regular, that they become the best criterion often for distinguishing the species of natural bodies. See CRYSTALLI.

If salts are dissolved in too much water, the superfluous fluid must be evaporated slowly until the salts show a disposition to concrete, even from the hot water, by forming a pellicle on the surface. If large, and the most perfect crystals are required, the solution must be removed from the fire before the pellicle appears; otherwise the sudden crystallization will diminish their perfection. In this case the evaporation must be continued until some drops of the liquor, falling on a cold glazed plate, discover crystalline filaments: the vessel must then be removed from the fire into a less warm, but not cold place, covered with a cloth, and left till crystals are formed. If the salt be pure, no more is necessary; but if not, filtration will be required, previous to the solution being left for the separation of its contents.

In crystallizing large quantities, sticks are placed, and sometimes threads, across in the vessels, on which the salts form, and are taken out in a more perfect figure than when they adhere in thicker concretions to the sides and bottoms of the vessels. Sudden cooling, or shaking of the vessel, will prevent the salts from being properly and regularly formed; and care should be taken that the substance of the vessels are such as not to endanger corrosion.

The figures of salts cannot be destroyed; for if they are comminuted ever so small, yet, upon re-crystallization, they form themselves again into their proper shape.

Salts entangle, in the interstices of their crystals, a portion of water, called the *water of crystallization*;

which occasions the efflorescence of salts in the air, and their effervescence on the application of heat: and on this their crystalline form seems much to depend. Nitre contains about one twentieth of its weight of water; alum one sixth; sea salt one fourth; borax, green vitriol, and the bitter purging salts, from one third to one half.

Rectified spirit of wine dissolves some salts, assists the crystallization of others, and is necessary for separating any oily matters from them. See MENSTRUUM and SOLUTION.

See Chaptal; Fourcroy; Lavoisier's Elements of Chemistry; the Encyclopedia Britannica; Boerhaave's Chemistry; Dictionary of Chemistry; Neumann's Chemical Works; Haüy Traité de Mineralogie; and Rome l'Isle's Crystallographie.

CRYSTA'LLUM MINERA'LE. See SAL PRU-NELLE, under NITRUM.

CRYSTALLOIDES TUNICA, (from *κρυσταλλος*, crystal, and *ειδος*, forma). See ARANEA.

CRYTHE. A hard, scirrhus, immoveable stian in the interior part of the eye lid, containing a pellucid body. See CHALAZA, CRITHE HORDEOLUM.

CTE'IS. See PUBIS OSSA.

CTE'NES. A COMB OR RAKE. Its plural means the *dentes incisores*.

CTESIPHON'TIS MALA'GMA. A plaster described by Celsus.

CU'BARIS. See ASELLI.

CUBE'B.E, (from the Arabic term *cubabah*). CUBEBS; called also *piper caudatum*; by Actuarius, *compheba*; and by Myrepsus, *compiper*. *Piper cubeba* Linn. Sup. 90. Wildenow, vol. i. p. 159. The cubeb tree is also the *baccifera arbor Brasiliensis fructu piper recipiente*. The berries are dried, of an ash brown colour, generally wrinkled, greatly resembling pepper, but furnished each with a slender stalk. They are brought from Java, and different parts of the East Indies; are a warm spice, agreeable to the smell, and somewhat pungent to the taste. Their qualities resemble those of pepper, but are much milder. Distilled with water, they yield a small quantity of essential oil, which possesses most of their virtue. An extract made with rectified spirit of wine abounds with all their virtues, for the odorous principle does not exhale with spirit.

Those which are large, plump, and heavy, are preferable; for if they are wrinkled, they have been gathered before they were ripe. See Raii Hist.; Neumann's Works; and Lewis's Materia Medica.

CUBE'BIS. See FAGARA MAJOR.

CUBIFO'RME OS, (from *cubus*, a cube, and *ειδος*, forma, likeness). See CUBOIDES OS.

CUBITA'LISNE'R VUS, (from *cubitus*, elbow). See CERVICALES. Cheselden describes the cubical nerves as being two in each arm: the upper passing over the upper exuberance of the os humeri, runs on to the thumb and the three next fingers by its branches, which spread when it approaches the thumb; the inferior, which passes under the inner exuberance of the os humeri, and runs on to the ring and little fingers. For this reason we find these fingers often affected, while the others remain free from disease.

CUBITA'LIS, vel ULNA'RIS ARTERIA. The cubital or ulnar artery, parting from the radical about a finger's breadth below the bend of the arm, sinks in

between the ulna and the upper parts of the pronator teres, perforates the palmaris longus, and radius inter-nus: near the carpus it lies just under the integuments, is continued on the inside of the os pisiforme, runs be-fore the annular ligaments across the palm, and forms an arch which anastomoses with that of the radial; whence these arteries go to the finger and thumb, one running on each of the fingers. In its course it sends off various branches.

CUBITA'LIS MU'SCULUS. See ANCONÆUS MUSCULUS.

CUBITA'LIS EXTE'RNA AND INTE'RNA, VENA. See BA-SILICA VENA.

CUBITI PROFUNDA VENA. Sometimes from one and sometimes from another of the branches called mediana, a branch goes out on the inside of the fore arm, which is thus named.

CUBITUS. The ELBOW; (from *cubo*, to lie down; because the ancients used to lie down on that part at their meals). *Olene*. (See ULNA). It is also a cubit measure; and in botany it is the ninth degree in the Linnæan scale for measuring plants. The length, from the elbow to the extremity of the middle finger, is esteemed equal to seventeen Parisian inches, or a foot and a half English. The stalks of plants are named *cubitalis*, or *bicubitalis*, according to their height.

CUBOIDES OS, (from *κῦβος*, a cube, and *εἶδος*, forma,) called also *os cubiforme*, *quadratum*, *grandino-sum*, *tessera*, *multiforme*, is situated immediately before the os calcis; on its fore side it sustains the os metatarsi of the little toe, and that toe next to it. The ossification of this bone is scarcely begun at the birth.

CUCOS. The kernel of the fruit of a species of palm tree; the fruit is the size of a cherry.

CUCULA'TUM MA'JUS. BRANDY, or SPIRIT OF WINE.

CUCU'LLA, CUCULLA'RIS MU'SCULUS, (from *cucullus*, a hood,) called also *trapezius*, arises by a strong round tendon, from the lower part of the protuberance in the middle of the os occipitis behind; and by a thin membranous tendon, which covers part of the splenius and complexus muscles, from the rough curved line that extends from the protuberance towards the mastoid process of the temporal bone; runs down the nape of the neck, where it seems to arise from its fellow, and covers the spinous processes of the superior vertebræ of the neck, but arises from the spinous processes of the two inferior, and all the vertebræ of the back, adhering tendinous to its fellow the whole length of its origin. It is inserted, fleshy, into the posterior half of the clavicle, tendinous and fleshy into the acromion, and into almost all the spine in the scapula. Its use is to move the scapula, according to the three directions of its fibres: for the upper descending fibres draw it obliquely upwards; the middle transverse straight fibres draw it directly backwards; and the inferior ascending fibres draw it obliquely downwards and backwards. Where it is inseparably united to its fellow in the nape of the neck, it is named *ligamentum colli*, or *nuchæ*. (Innes). It is observed by Douglas, that Galen divides this muscle into two, viz. the superior and the inferior. The first he calls the *trapezia*; and to the second later anatomists have given the name of *cuculla*, from whence they are both commonly named *cucullares*. Its upper part, from the os occipitis to the spinal process of the last ver-

tebræ colli, is inseparably united to its fellow of the other side.

CUCULLA'TA, (from the same). See SANICULA.

CUCULLA'TI FLORES, (from the same). CU-  
CULATE FLOWERS. See FLOS LABIATUS.

CUCULLA'TUS, (from the same). In botany it means rolled up like, or covered as with, a hood.

CUCU'LLUS. A FLOOD. See CUCUPHA, and EPI  
THEMA.

CUCUMERA'RIA, CUCUMERI'NA I'NDICA, (from *cucumis*, the cucumber). See MOMORDICA.

CUCU'MIS, (quasi *curvimeres*, from their curvature, according to Varro). The CUCUMBER. The cucum-ber hath a flower consisting of one leaf, which is bell-shaped, expanded toward the top, and cut into many segments, of which some are male, others female. The best fruit is long, and of a deep green. This plant is annual, and raised from seed, the best of which is long and thick, with a thin rind. See CUCUMIS HORTENSIS.

CUCU'MIS AGRESTIS; called also *cucumis asininus*, *elaterium officinarum boubalios*, *guarberba orba*. The WILD OR SQUIRTING CUCUMBER. The fruit from whence the elaterium of the shops is obtained, is the *momordica elaterium* Lin. Sp. Pl. 1434. This fruit is watery, hairy, and almost of an oval shape, about two inches in length: when ripe, it bursts on being touched, and throws out with violence its whitish juice and black seeds. It is sown in our gardens annually, but is found wild in many other countries. The Greeks call it *elaterion*, from *ελαυνω*, to dart; and from whence it is called the *squirting cucumber*. The same term is applied to any purging medicine that acts with violence. All the parts of the wild cucumber are strongly purgative; the fruit is the most so, and the root more active than the leaves. The juice of the fruit hath an unpleasant smell, and a durable nauseous bitter taste: on standing a few hours, it separates into a thick part, which falls to the bottom, and a thin watery fluid, which floats above. The dried juice, or *fæcula* of the fruit, known in the shops by the name of *elaterium*, is the only part now medicinally employed, and has been distinguished into white and black elaterium: the first is prepared of the juice which issues spontaneously, the latter from that which is obtained by expression. It is a strong, irritating, but slow, cathartic; and often operates with violence as an emetic, disappointing the practitioners in its other effects. It remarkably raises the pulse, appearing to excite for a time a feverish state; and is, therefore, only used in cold phlegmatic constitutions, and in dropsy, a disease in which it was much employed by Sydenham and Lister. (See Sydenham's Works, and Listeri Exercitationes Medicinales de Hydrope). It is undoubtedly the most violent purgative in the materia medica, and ought, therefore, to be administered with great caution, and only where the milder cathartics have proved ineffectual. The dose is from half a grain to three grains: the most prudent and effectual mode of exhibition in dropsies is by repeating it in small doses, at short intervals; or employing it to quicken other purgatives. Four grains of extract of gentian, and a quarter of a grain of elaterium, formed into a pill, and repeated every two hours till it operates sufficiently by stool, and given every third or fourth day, is said to have been effi-cacious in reducing dropsical swellings, and affording an opportunity for the exhibition of tonics.

The London college directs the following method of preparing elaterium:

Slit ripe wild cucumbers, and strain the juice, very gently pressed, through a very fine hair sieve, into a glazed vessel; set it by for some hours, till its thicker part shall have subsided; then pour off the thin part of the juice, and separate the rest by straining; let the thicker part which remains be covered over with a linen cloth, and dried by a gentle heat. Pharm. Lond. 1788.

Care should be taken not to press the cucumber so as to force out any of the pulp; for thus the preparation will be proportionably weakened. An extract made with wine from the roots is equally useful with this fæcula, called elaterium.

Elaterium is mentioned as a purging medicine by Hippocrates: sometimes it occasions great uneasiness in the bowels, if too large a dose is given; in which case acids and mucilages are the proper antidotes. See Raii Hist.: Lewis's *Materia Medica*; and CATHARTICS.

CUCUMIS ÆGYPTIUS. CHATE, or EGYPTIAN CUCUMBER. It is more white, soft, and round than our garden cucumber, but of similar qualities.

CUCUMIS CANADENSIS. See SICYOS.

CUCUMIS COLOCYNTHIS. See COLOCYNTHIS.

CUCUMIS HORRENSIS, *cucumis vulgaris*, *cucumis sativus*, or GARDEN CUCUMBER.

The seeds of this species are the only part used in medicine. They have usually been prescribed in a mixture of equal portions of the seeds of the citrullus, or watermelon; cucurbita, or gourd; and pepo, or pompon; under the general name of the GREATER COLD SEEDS. The seeds of all these plants are similar in their medicinal properties. The fruit of the cucumber is not very nutritious, though it makes a considerable part of the aliment of many persons in warm climates and seasons; and its aqueous and cooling quality renders it very proper for summer aliment, and an agreeable food in hot, bilious dispositions. From the sponginess of its texture, it is often retained long in the stomach, occasioning acidity and flatulence; hence it should be accompanied with a large proportion of aromatics. Formerly the seeds were beat into an emulsion with other ingredients, but now are rarely employed, the almond emulsion superseding their use.

CUCUPHA, A HOOD; called also *cucullus*, *birethus*, and *pileus*. An ODORIFEROUS CAP for the head. It is made like what is called the skull cap, for children, of either silk or linen; double, containing between its folds cephalic aromatic drugs, in powder; sometimes they are mixed with cotton, to keep them equally dispersed; sprinkled with some suitable essential oil, with spirit, or vinegar. When applied to half of the skull, or a particular part, it is called a *semicucupha*. The ingredients should be renewed when their virtue is exhausted. Indeed all the virtues these caps possess will soon be lost, for the aromatics can be of little use. The double cap may possess some virtue; and, as in the oriental tale of medicines, concealed in the racket, the adventitious circumstances may be truly salutary. The proportions of the species usually recommended are, of roots, an ounce; of leaves, two or three handfuls; of flowers, two or three pugils; of gums, one or two drachms; of powders, one ounce: the whole rarely exceeds four ounces. See EPITHEMA.

CUCURBITA, (*a curvitate*; from its shape). *Cucurbita lagenaria* Lin. Sp. Pl. 1434. The GOURD. It is a large fruit growing on a plant: its seed is one of the four cold seeds mentioned in the article CUCUMIS. It is also a glass vessel with a round belly and a long neck, about six inches diameter, and firmly closed; *bocia*, *botus barbatus*, and *ovum sublimatorium*.

CUCURBITA. A CUPPING GLASS. (See CUCURBITULA). Also a CUCURBIT; *alkara obelchera*. A chemical vessel, so called from its resemblance to a gourd; for it gradually arises from a wide bottom, and terminates in a small neck. Some call it *vas urinale*, because it is shaped like a glass in which urine is inspected. It is used in distillation, with a head, and then it constitutes an alembic: it is also used in digestions, with a blind alembic fitted to it.

Cucurbits are made of glass, earthen ware, or of metal, according to the respective uses in which they are engaged: the earthen ones are called *canthari figulini*; the copper ones are lined with tin, *vesicæ distillatoria*.

The broader the bottom, and the narrower and longer the neck, with the more difficulty its contents are distilled; so that the less obedient any subject is to the fire, the narrower the bottom, and the shorter the neck should be, and *vice versa*.

It is a blind cucurbit, when another small cucurbit is placed on with its neck in the neck of the larger. The lesser are called separatory cucurbits. If its belly is spherical, and its neck long and cylindrical, it is called *matracium*, a MATRASS, or a BOLT HEAD.

The length of its neck is such, that scarcely any of the liquor ascends to its mouth, the cold external air repelling it again to the bottom of the vessel. Thus the digestions of menstrua, with the substances to be resolved in them, are conveniently carried on without any loss. They are used for macerating and digesting various ingredients: they are also used as receivers, and take different names from their different shapes. Besides these advantages, the long necked cucurbits are singularly useful in separating pure alkaline or volatile spirits and salts from water, oil, and volatile earth. Cucurbits are more used for digesting and subliming, than for distilling. See Dictionary of Chemistry.

CUCURBITA CITRULLUS. See CITRULLUS.

CUCURBITACEÆ, (from *cucurbita*, a gourd). An order in Linnæus's fragments of a natural method.

CUCURBITIFERA MALABARIENSIS, (from *cucurbita*, a gourd, and *fero*, to bear). NUX VOMICA.

CUCURBITIFERA TRI'FOLIA INDICA FRUCTUS PULPA CYDONII Æ'MULA. See COVALAM.

CUCURBITULA, (*a dim. of cucurbita*; so called from its shape). A CUPPING GLASS; an instrument of great antiquity, being mentioned by Hippocrates, and formerly made of horn or metal. Different names have been given to them, according as they were used with or without scarifications, as *leves*, *arentes*, *siccata*, &c. The ancients employed them with narrow mouths for drawing more forcibly, and with wider mouths for drawing more gently, as they were exhausted by the breath. The principle on which all cupping glasses act, is the exhaustion of the air; from which the parts under the glass rise in it, and their vessels, when the

pressure is removed, are distended. The delicacy of the operation consists in exhausting the glass so far that the vessels under it may be filled, but not that the edges of the glass may press so firmly around as to impede the circulation; a medium, it may be supposed, easily preserved: yet the operation, except in the hands of professed artists, often fails. The failure is not of consequence when cupping only is employed; but if evacuations are also required, this error renders them trifling or ineffectual. When scarifications are not wanted, it is termed *dry cupping*.

The old mode of applying a cupping glass, now obsolete, was to expel the air by heat: the wick of a spirit lamp, or a little inflamed tow, was put within the cupping glass, which was, after a little time, applied to the part, to which it adhered with a strong attraction, as the air was rarefied. At present the air is exhausted by an air pump. The use of dry cupping is to invite the fluids to the place where the glass is applied, in order to remove them from the internal parts. The operation should be repeated until the part becomes red, and is in pain. It very nearly resembles, in its operation, blisters; and the scarifications supersede the use of leeches. We have found them equally effectual.

When scarification is used with cupping, the part should first be dry cupped until it appear red; then the incision should be made with the scarificator. If scarifications are to be made in several parts, it is more convenient to begin below and proceed upwards. After the scarifications are made, the air must be excluded from the glass, when, from the pressure around, the vessels usually bleed freely. When the operation is ended, to stop the bleeding a little spirit of wine may be applied; but sometimes warm water, with a slight pressure, is sufficient.

This operation seldom seems necessary, except when blood cannot be obtained by opening a vein in the usual manner. Celsus, lib. ii. cap. 11, observes, that "cupping is needful when the body is to be relieved in some acute disorder, and yet the strength does not admit of a loss of blood from the veins." It is true, that the slow discharge of blood by cupping does not lessen the force of the arterial system so much as the same quantity of blood suddenly taken away from a vein; but in such cases, as Celsus supposes, some evacuation is often necessary, and no other is admissible except bleeding by leeches.

Cupping has been preferred in apoplexies, epilepsies, and some kinds of convulsions, because the spasms are supposed to be increased by the speedier discharge of blood which is the consequence of phlebotomy; but they are in reality more useful, because the plethora is local rather than topical.

See Cælius Aurelianus, Celsus, Morgagni, Hoffman, Haller, Bell's Surgery, vol. i. p. 154, &c. White's Surgery, p. 180.

CU'DU PARI'TI. (Indian.) A shrub which grows in Malabar: it flowers through all the year. The leaves are anodyne when externally applied; and the fruit checks a dysentery. Raii Hist.

CUE'MA, vel YE'MA, (from *κωμ*, to carry in the womb). See CONCEPTIO and EMBRYON.

CULB'CIO. A strangury, or rather heat of urine. See DYSURIA.

CULE'US, or CULLE'US. A Roman measure containing twenty amphoræ; the largest liquid mea-

sure among the Romans: sometimes it signifies a leather sack.

CULI FLOS. See CARDAMINES.

CULINA'RIOUS SAL, (from *culina*, a kitchen). The CULINARY or ALIMENTARY SALT. It is generally called COMMON or SEA SALT, because of common use in culinary preparations. Sea salt consists of the pure muriatic acid, and the salt usually called Epsom salt, or salt catharticum amarum. When sea water is evaporated, the first crystals are the culinary salt. When these are separated from the remaining brine, and the evaporation continued, crystals of the bitter purging salt of the shops follow. The constituents of the culinary salt are, the muriatic acid, and a mineral alkaline salt. See MARINUM SAL, and CHEMISTRY.

CULI'LTLAWAN. See CORT. CULILAWAN.

CULLENIAN SYSTEM. The Cullenian system forms an era in the history of medicine, which, from various causes, may perhaps escape the notice of future inquirers; for the physicians on the continent had scarcely escaped from the trammels of Boerhaave, before the eccentricities of Brown caught their attention; and to him they look for that revolution in the science, which taught that the functions of a living being were to be explained only by the laws of animation. Causes, already hinted at, have obscured the lustre of Dr. Cullen's fame; and it is left to a son to explain why the character of a father must be rescued from oblivion by strangers.

The early years of Dr. Cullen were spent in active life. He had few opportunities for study, but many for observation. Nature had given him an intuitive sagacity, which caught at every fact, and stored it advantageously for future use. Of his chemistry we have had little information; but, during his holding the professorship of chemistry, he gave a private course of pathology. This must be explained. The institutions of medicine comprehend physiology, pathology, hygieinè (the doctrine of health), and therapeutics, the general doctrines of remedies. In the university of Edinburgh, at that period, the professor of the institutions confined his attention chiefly, and almost exclusively, to the first branch. The other subjects, therefore, confessedly of importance, were left open to any enterprising teacher. Such, apparently, at that time was our author; for we have many reasons to convince us, that even at this time he aspired to be the founder of a sect. In the pathology he had the best opportunities for laying his foundation; and the additional advantage of illustrating his principles by experience in the clinical lectures, which he gave at this time in the infirmary. We have seen some extracts from these lectures, and find in them the germ of his future system; the embryo, already formed, which required only to be evolved and augmented.

His fame gradually expanded till the year 1763, when an accidental circumstance rendered it more brilliant and extensive. In 1763, Dr. Alston, the professor of materia medica, died in the midst of his course; and Dr. Cullen either offered or was requested to continue it. A common genius would have copied in the moment of exigency, or repeated, with the slight variation which his own opinions suggested, the lectures of his predecessor. Dr. Cullen started at once into a new path, bold, comprehensive, and original. We remember our first opinions of it; and now that thirty-five succeeding years have cooled our ardour, uninterrupted study

and practice added to our information, we can decidedly pronounce that his plan has not been excelled; has not *publicly* been equalled. We take it not from the improved edition of the author himself, but from the outline in the lectures originally delivered.

While our astonishment is excited by this apparently sudden display of talent, of united genius and industry, we must reflect that he had taken his degree; and, at the age of thirty-four, was elected professor of chemistry in Glasgow. This professorship he retained five years, when he was appointed professor of medicine in the same university. Five years after that period he became professor of chemistry at Edinburgh, viz. in 1756; and in 1763 did he continue the course of Dr. Alston. Seventeen years may have been, and probably were, employed in maturing a system which, with all its imperfections, is a splendid monument of genius; and though private practice, convivial hilarity, and the duties of his chemical chair, must have employed many of his hours; yet industry, a habit of early rising; above all, an able, comprehensive mind, which, at once catching the principle, included innumerable consequences, enabled him to retain a vast fund of medical erudition, and to complete those extensive views which seem already to have assumed a consistent form.

In 1765 he approached nearer to his object, by his appointment to the chair of the institutions of medicine, vacant by the death of Dr. Whytt; and, in 1769, the agreement between him and Dr. Gregory, to give alternately courses of the theory and practice of medicine, was carried into effect. These professors, at the same time, agreed to divide the clinical course.

It is not our subject to write the life of Dr. Cullen; but the events detailed are connected with our views of his system, and we have been enabled to add some facts, and correct some dates in the only narrative of his life which has any pretensions to accuracy, viz. that in the Supplement to the Encyclopedia Britannica, from our own knowledge.

The foundation of Dr. Cullen's system is, as we have hinted, considering the human body as a congeries of animated organs, regulated by the laws, not of inanimate matter, but of life, and superintended by an immaterial principle, acting *wisely*, but *necessarily*, for the general health; correcting deviations, and supplying defects, not from a knowledge and choice of the means, but by a pre-established relation between the changes produced, and the motions required for the restoration of health.

This principle, in its various ramifications, influenced every part of his theory of medicine. The circulation was no longer to be explained by mechanical laws; the angles at which the branches of the larger arteries diverged, were shown to have little influence; lentor, viscosity, and acrimony, either acid or alkaline, were proved, if they existed, to have no influence in producing diseases. The whole was resolved into motions, regulated by the living principle, and chiefly influenced by the action or torpor of the extreme arteries.

This total revolution in the science was received by the younger with the stare of admiration, by the elder with doubt, suspicion, and dislike. From the system of Boerhaave there had been hitherto no appeal; and to doubt his theory was to undermine the whole fabric of medicine. Dr. Cullen was certainly considered for a time as a fanciful innovator; but, whatever may have

been the deviations from his system even in Brown and Darwin, still it must be considered that each adopted the same great principle, and explained the functions of a living system by the laws of animation.

It is singular, however, that it did not occur to those who animadverted on or opposed the Cullenian system, that it was by no means wholly new or fanciful. The connection of the state of the extreme vessels with the general system had been pointed out, in many places, by the industrious and attentive Hoffman; and the general regulations of the living principle, by Stahl. We have been often tempted to accuse Dr. Cullen of dissimulation in concealing the labours of Stahl. He slightly mentions one essay on "The Tertian, as the general Type of Fever," and his "*Theoria Medica Vera*:" chiefly with a view of combating his principle, that the mind provides for those exigencies by a knowledge of the change to be produced, and that its superintending power adapts the means to the end; but the commentaries on different parts of the latter, where the system is more fully developed and explained with the most logical precision, we mean in the inaugural dissertations published at Halle, during his presidency, our professor never mentions. The dissertation, "*De Motu Tonico*," and "*Æstus Maris Microcosmici*," contain the principles of the Cullenian doctrine, though in no very inviting form or language.

We might now dismiss the subject, referring, for more particular information, to the different articles as they occur; but the admirers of Dr. Cullen will probably expect a somewhat more particular account of his doctrines. We shall, therefore, pursue them a little more minutely.

He considers the primordial stamina of the human body as fibrous. Such is the structure of the brain, the nerves, the muscles, and the various membranes; but these fibres are not, as Boerhaave supposed, connected by a cementing matter, but a peculiar solid, consisting of parts united by chemical attraction. The growth of the body he supposes to be owing to the extension of the arteries and the nutritious fluid prepared by the brain, and deposited in the interstices of the fibres by the nerves. This extension of the arteries is effected by the force of the heat; and on the proportion of this force to the resistance, many of the changes in the animal economy, both in its advancing and decaying state, are, he thinks, owing.

The muscular fibres he styles "the moving extremities of the nerves," and supposes them to be a continuation of the extremities of nerves. He denies that the muscles have a vis insita, independent of the nervous power, as Haller supposed; and thinks that the contraction of muscular fibres is only an increase of the common power of cohesion, by an accumulation of the nervous influence.

This influence he supposes not to be secreted by the brain from the blood; but to be generally inherent in the nerve, and, indeed, to be a part of it. Sleep and watching are not, therefore, owing to the exhaustion of the nervous influence or its accumulation, but to its state of torpor or excitement.

The simple solids he supposes, as already mentioned, to be a chemical mixture, consisting of fibres, with a more simple animal substance interposed. They differ in strength, cohesion, &c.; but in this respect they

follow the state of the constitution, or rather of the nervous system. From this all their deviations are derived; and to this all our views for the restoration of their healthy state must be directed. The fluids are formed also by the constitution. The superintending power regulates their deviations from their proper state of mixture, by increasing the different secretions adapted to carry off particular portions when in excess, or checking these discharges when the quantity of the whole mass or any of its component parts is deficient.

As a machine, the whole is regulated by the state of the brain, of the stomach, and of the extreme vessels. These mutually influence each other; and when one is disordered, the others suffer. When the spasmus periphericus of Hoffman exists, the stomach sympathises, and vomiting comes on, which is often not removed till sweat breaks. When the head is loaded, vomiting equally occurs; and an affection of the stomach will produce shivering, headach, palpitation of the heart, and almost every other complaint. The ligaments, particularly of the extremities, have, in our author's opinion, a striking connection with the state of the stomach; but this rests on some facts which are doubtful, or which may be otherwise explained.

From these principles all the leading traits of his system emanate. To pursue them in particular detail, or distinct complaints, is not proper in this place: they will frequently occur in almost every sheet of this work. In our opinion, it is a most astonishing effort of genius and ingenuity: when the period of its publication is considered, it is still more wonderful. The whole is combined with so much judgment, that it fills the mind as one whole: nothing is wanting; nothing redundant. The chain is complete; and it is a chain of facts supported by observation. To suppose it faultless would be ridiculous; yet those who oppose it, have borrowed from their master's powers the facts and arguments adduced against it. Dr. Cullen succeeded well; but his greatest success was what he professed to aim at, the improvement of his pupils' judgment; the raising a host of critics on himself.

It will have been obvious, from the preceding pages, that we have in general followed Dr. Cullen; or rather, that we have given a temperate view of our professor's opinions, adding to, modifying, and sometimes differing from, them. One very important addition we have professed to take from Dr. Brown, viz. accumulated and exhausted irritability; and one very material alteration we have made, in considering convulsions not as increased but irregular action. "As we are now at *shrif*," we may add, that we follow no man's *ipse dixit*. No opinion shall be hazarded in this work that has not been fully considered, brought to the test of experience, and examined in all its bearings and connections. If wanting, when "weighed in the balance," it shall be stated as uncertain, doubtful, or hazardous. At least, we will not knowingly mislead.

If we follow Dr. Cullen's system in its practical deductions, we shall not speak of it with equal commendation. As a practitioner, he was often feeble and indecisive; nor do his doctrines always lead to the most active and successful measures. The error is, however, chiefly in the application: we shall show that it is not in the principle. A striking instance of this error we shall have occasion to notice in the treatment of fevers.

VOL. I.

With a view to relax the spasm, the use of the antimonials was commenced early, and continued with somewhat too great pertinacity: but, if the spasm arose from debility, if the reaction was unable to conquer it, still less would a debilitating power succeed; and, in reality, while the employment of antimonials was eminently useful in the early stages, when the reaction was strong, and the general principle contributed to give a fatal blow to the doctrine of concoction, its promiscuous use has been highly injurious. We have now employed Cullenian language, not our own.

We have not mentioned our author's nosology, because it was not, in reality, a part of his system. It must rest on other grounds, and be the subject of a future article. It is only mentioned at present to point out a most important part of Dr. Cullen's instructions to his pupils, viz. the necessity of an accurate diagnosis. This he thought was best ascertained by nosological arrangement; and he added, what we believe to be strictly true, that no nosological difficulty can occur, which does not imply the defect of accurate observation, or lead to a more attentive examination of the symptoms of a disease.

CULMEN, CULMUS, (from *κάλυμος*, a reed). The STALK OR BLADE OF CORN OR GRASS. Culminiferous plants have a smooth jointed stalk, are usually hollow, and at each joint wrapped round with single, narrow, sharp pointed leaves: their seeds are in chaffy husks, as wheat and barley.

In grasses and corn, the culm or stalk corresponds to the caudex or trunk of trees; so that it generally denotes that part between the root and the ear or panicle. The stubble of corn remaining after the ears are cut off, is strictly the culmen.

CULMINIFERÆ, (from *culmen*, the top). The twenty-fifth order in Linnæus's Fragments of a Natural Method.

CULTER, (from *colo*, to cultivate). A knife or spear. The third lobe of the liver, named from its resemblance. See AURIGA.

CULUS, (*κουλός*). See ANUS.

CUMA'NA. (Indian.) Called also *gacirma*. An Indian tree like that of the mulberry tree, whose wood is so hard that it strikes fire like a flint.

CUMBULU. (Indian.) Called also *nux Malabarica unctuosae flore cucullato*. A tall tree growing in Malabar, the root of which is used in a decoction with rice for common drink in fevers. Neither this nor the cumana is to be found in the systems of the botanists.

CUMINOIDES, (from *κuminum*, cummin, and *ειδος*, likeness). WILD CUMIN. Called also *cuminum sylvestre*, *pastinaca tenuifolia Cretica*, and *daucus odoratus Creticus*. *Lagæcia cuminoides* Lin. Sp. Pl. 294.

This plant grows in Crete: the seeds only are in use; they are carminative. Raii Hist.

CUMINUM. CUMIN. (From *κυσιν*, to bring forth; because it is said to be efficacious in curing sterility.) It is also called *cuminum* and *feniculum orientale*. It is the *cuminum cyminum* Lin. Sp. Pl. 365.

This plant resembles fennel, but is much smaller; produces longish, slender, plano-convex seeds, of a brownish colour, with yellowish striae; is annual; a native of Egypt and Ethiopia. It is cultivated in Sicily and Malta, from whence it is brought to us, chiefly for

its fruit, which has an aromatic, sharp, and slightly bitter flavour; a strong and not unpleasant smell.

The Dutch mix the seeds with their cheeses, the Germans with their bread; and pigeons are fond of them. Water takes up their odoriferous particles by infusion, though but little of their taste. Distilled with water they afford a pungent oil, which resembles in flavour the seeds. Rectified spirit extracts their whole virtue: the spirituous extract is very warm, moderately pungent, and not a little nauseous.

These seeds are carminative and stomachic, and possess these powers in an equal or superior degree when compared with the other plants of the umbelliferous class; but they are rather unpleasing. Externally they are discutient and antiseptic; affording, when applied to the stomach, a warm and salutary stimulus.

The *cataplasma cumini*, formerly *theriaca Londinensis*, of the London college, consists of cumin seeds, one pound; bay berries, the leaves of water germander dried, Virginia snake root, of each three ounces; of cloves, one ounce: with honey equal to thrice the weight of the powders. (Ph. Lond. 1788.) This was formerly applied to mortified parts as an antiseptic, but is now seldom used, though by no means an ineffectual remedy.

*Emplastrum cumini*, consists of Burgundy pitch, three pounds; yellow wax, cumin seeds, caraway seeds, and bay berries, of each three ounces. The pitch and wax are melted together, the seeds and berries are gradually added and stirred well together. (Ph. Lond. 1788.) This is considered as a suitable application to encysted and other tumours, which suppurate imperfectly. See Miller's Dictionary. Lewis's Materia Medica. Raii Hist.

CU'MINUM ÆTHIO'PICUM. See AMMI VERUM.

CU'MINUM PRA'TENSE. See CARUM.

CU'MINUM SILIQUOSUM, is the CODDED WILD CUMIN. It grows in Spain, flowers in May, and produces the same effects, medicinally, as the poppy. *Hypocoum pendulum* Lin. Sp. Pl. 181.

CU'MINUM SYLVESTRE. See CUMINOIDES.

CUNEA'LIS SUTU'RA, (from *cuneus*, a wedge). The suture by which the os sphenoides, or cuneiforme, is joined to the os frontis.

CUNEIFORME OS, (from *cuneus*, a wedge,) *clavicula*, *cavilla*, *Chalcoideum os*, *Basilare os*. A name of the os sphenoides, from its being wedged between the other bones. Also the third bone of the first row in the wrist; called so from its appearing like a wedge sticking between the two rows. See CARPUS.

CUNEIFORME OS EXTE'RNUM, or *chalcoideum externum* of the tarsus. At its posterior edge it joins the os naviculare and os cuboides; it supports the metatarsal bone of the toe next the little one, and that next the great one and of the middle toe. The os cuneiforme medium vel minimum, is still more wedge-like than the former; it sustains the metatarsal bone of the toe next to the great one. The os cuneiforme internum vel maximum sustains the os metatarsi of the great one. All these are cartilaginous at the birth of children. These bones are also called *chalcoidea ossicula*.

CUNILA SATIVA, (from *κονίλη*). See SATUREIA SATIVA.

CU'PELLA, (from *kupfel*, Germ.). Called also *copella*, *catellus cinereus*, *cineritium*, *fatella docimastica*,

*testa probatrix*, *exploratrix*, or *docimastica*. A CUPEL or TEST.

These are vessels used for separating baser metals from gold or silver; they are made of earth, and are hollowed like flat cups, from which they have been named: they resist every degree of fire that is needful to keep any metal in fusion, and retain these metals when fused; but the calces of some metals, particularly of lead, penetrate the common cupels. The ashes of bones or of plants that have been calcined are therefore employed, though Cramer prefers those made with plaster: and later chemists prepare them of gold or platina. The bone ashes must be perfectly calcined, then levigated; after which they must be formed into a paste, moulded into their proper form, and burnt in a potter's furnace. See various directions concerning them in the Dictionary of Chemistry.

CUPELLATION. A chemical operation by means of a cupel. It is employed to separate the purer from the baser metals, by scorifying the latter.

CUPERO'SA, (from *cuprum*). COPPERAS.

CU'PHOS. LIGHT. When applied to aliments, it imparts their being easily digested; when to distempers, that they are mild.

CUPRESSUS, (*απο του κυειν παρισους τους ακρεμονας*, because it produces equal branches). Called also *cyfarissus*. CYPRESS TREE. *Cupressus sempervirens* Lin. Sp. Pl. 1422. It is a tall evergreen tree, native of the warmer climates, bearing male and female flowers on the same branches: the leaves are slender, and so are the branches, which spread, forming a cone, the apex of which is the top of the tree; the fruit is a kind of nut called *galbulæ* and *glabulæ*, as large as a walnut, and astringent. The flowers have an agreeable odour, and have been used in conjunction with some other ingredients for making an oil, by infusion with olive oil, named *oleum cyprinum*.

CUPRESSI'NUM. CYPRESS WINE. See CEDRI'NUM.

CU'PRI AMMONIA'TI A'QUA, (from *cuprum*, *copper*.) *olim*, *aqua saphirina*, called *collyrium cæruleum*.

Take of lime water, one pint; sal ammoniac, one drachm; let them stand together in a copper vessel until the ammonia is saturated. Phar. Lond. 1788.

CU'PRI PREPARATIO'NES. PREPARATIONS OF COPPER. See ÆRIS FLOS.

CU'PRI RUBI'GO. See ÆRUGO ÆRIS.

CU'PRUM, (quasi *æs Cyprum*; so called from the island of Cyprus, from whence it was brought). See ÆS. In this article we chiefly enlarged on the chemical properties of copper, reserving our account of its medical virtues and its different preparations to this article, where it would be more naturally sought.

In a medical view, copper supports, in a singular degree, the canon of Linnæus, that medicines differ from poison, not in quality, but in power. Its quality is not essentially different from those of iron and zinc; yet copper, in a moderate quantity, disorders the stomach and bowels, producing inflammation and its most fatal consequences. In moderate doses, like all other metals, it is a sedative, a tonic, or antispasmodic. When taken in larger quantities, it produces nausea, with a constant taste of the copper remaining in the back part of the fauces: violent vomiting; the most dreadful oppression on the breast; the most acute pains of, and a

burning heat in, the stomach; colic; vertigo; bloody stools; watchfulness, increasing to delirium; faintings; convulsions; paralysis; and apoplexy; frequently with eruptions on the skin; sometimes resembling lepra.

Such are nearly the symptoms arising from copper imprudently or accidentally taken; and the authorities which now lie before us of the dangers arising from it, would fill more than our page. Yet such is the nauseous taste of this metal, that, in general, it guards the victim from its influence; for the flavour of copper would certainly alarm the most incautious person of its danger, if it approached under the disguise of aliment. In medicine it cannot be always discovered; and the great danger of employing vessels which have any proportion of copper in their composition, has been properly pointed out by Mr. Blizard and others.

When copper has been inadvertently swallowed, emetics are seldom necessary. The vomiting they excite is sufficiently active; but should sickness, with violent pain in the stomach, ensue without vomiting, as sometimes happens, a few grains of the vitriol of zinc will be effectual. If an emetic is not required, mucilaginous substances, as oil, butter, and milk, will be useful; and, with these, an alkali will contribute to mitigate the virulence of the poison. Each of these meet in soap. The most appropriate antidote, however, is the sulphurated alkali (hepar sulphuris), which may be given with milk or with mucilages.

The most common artificial forms of copper, as verdigris, æs ustum, &c. we have noticed in their proper places. We shall therefore mention a few more rarely described. The *filings of copper* are recommended by Struve in the bite of a mad dog; and this preparation has been formerly recommended as a laxative, a diuretic, and a sialagogue. It is recommended also by Cotheuius in malignant and venereal ulcers.

The *flos æris* is copper in a capillary form, which it acquires by sudden cooling; and it has been recommended as an attenuant by Dioscorides. The *sulphur of copper* is a dark green powder, prepared by precipitating copper from an acid by means of a plate of iron. This precipitate is triturated with four parts of quicksilver in a glass mortar, and then suspended for a month in a gentle heat; after which the copper is separated, by triturating the mixture with rain water. It has been recommended in epilepsies, but has deceived some of its warmest patrons.

Various are the liniments, cerates, and plasters, to which the preparations of copper impart their colour, and give a name. These, however, belong to extemporaneous prescriptions, which we shall afterwards notice; yet as not generally known, we may mention the following.

The *balsamum viride* consists of verdigris, boiled with turpentine and linseed oil. It has been considered as powerfully deturgent in old foul ulcers.

The *cera viridis*, employed by Platner in softening, or rather eroding, corns, consists of verdigris, combined with yellow wax, resin, and turpentine. This greatly resembles a plaster highly recommended in the Journal de Medecine, composed of verdigris, combined with yellow wax, and gum ammoniac.

The *magisterium cupri* of Sala differs little from the green crystals of copper; and the *aqua viridis* of Hartman is composed of equal portions of verdigris and burnt alum, a double portion of honey, with thirty-

two parts of white wine. It is supposed to be highly useful in cleansing foul ulcers of the gums, and other parts, whether they proceed from a venereal or a scorbutic source.

The *tinctura cupri alkalina* differs little from the ammoniated copper, to be afterwards described. It is a solution of calx of copper, by means of ammonia, with the alkali in excess. Boerhaave recommends it to be prepared by the filings of copper; Hecker, with the erugo; but both recommend it for cancers and venereal ulcers. It is also supposed useful in tooth ach, conveyed by means of cotton to a hollow tooth; by Lieb, in epilepsy; by Boerhaave, in dropsy. Many *blue lunar tinctures* of the ancients are probably derived from the alloy of copper in silver; and the *tinctura martis cœrulea* of the Wirtemberg Pharmacopœia seems to derive its virtue and its colour from an accidental mixture of copper.

The *tinctura æris vinosa*, so effectual, if we believe Sala, in destroying leucomata on the eyes, is prepared from filings of copper in wine. The more common extemporaneous formulæ we shall add.

*Cupri Calx.* R. Cupri vitriolati q. v. solvatur in aquæ distillatæ, q. s. et adjiciatur kali præparati portio propria, donec cuprum ad vasis imum descendat, deinde bene lavetur, et siccetur.

*Cupri ammoniati liquor.* R. Calcis cupri ʒ i. aq. ammoniæ ʒ ij. These are to be digested without heat till the copper is dissolved.

*Cupri acetati injectio.* R. Æruginis gr. x. olei amygdal. ʒ iv. m. trituratione donec solvatur in oleo ærugo.

*Cupri ammoniati injectio.* R. Liquor. cupri ammoniati, g. xx. aq. rosæ ʒ iv. m.

*Cupri vitriolati injectio.* R. Cupri vitriolati g. iv. aquæ distillatæ ʒ iv. m.

These injections are of the astringent class, and calculated for the latter stage of gonorrhœa. The ammoniated one is considered by Mr. Foot, and recommended, as a remedy preferable to all others of this nature. Practitioners should be cautious in the use of astringents: they should be first introduced in very small quantity, and gradually increased; indeed, till the inflammation is considerably abated, they are scarcely at all admissible, and much mischief has been done by their too early administration. The following has been highly useful in that symptom called phimosis, which has been supported by ulcerations within the prepuce.

*Cupri vitriolati composita injectio.* R. Cupri vitriolati g. vi. aquæ distillatæ ʒ iv. aquæ lithargyri acetati g. xx. m. Cupro vitriolato prius soluto, adjiciatur lithargyrum acetatum, et interpræputium, et glandem penis injiciatur, et pro ratione effectus caute repetatur.

*Cupri vitriolati pilulæ.* R. Cupri vitriolati g. xx. Olibani, extract. cinchonæ, āā ʒ ij. syr. sacch. q. s. ut fiant pilulæ quadraginta. Dosis, ab una ad quatuor indies. These are calculated to remove gleet, and are sometimes advantageous in the latter stages of gonorrhœa.

*Cupri vitriolati camphorata aqua.* R. Cupri vitriolati, bol. gallici āā ʒ ss. camphoræ ʒi. aquæ ferventis lb iv. Adjiciatur aqua ingredientibus aliis, et quando frigida fiat, per chartam coletur. This is the camphorated water of Bates in a diluted state; it is chiefly

employed as a collyrium, but may be usefully applied to foul ulcers.

*Cuprum ammoniacum*. AMMONIACAL COPPER. (Phar. Edin.) Take of purest blue vitriol, two parts; volatile alkali of sal ammoniac, three parts: rub them briskly in a glass mortar till the effervescence is finished, and they run calmly into a violet coloured mass, which is to be rolled up in a piece of bibulous paper, and exsiccated, first upon a chalk stone, and afterwards with a gentle heat, then put up for use in a close phial: this is a very active medicine, used for the same purposes, and in the same manner, as VITRIOLUM CÆRULEUM, which see.

It may appear singular that the mixture of two dry powers should be ordered to be dried; but the moisture on mixing them arises from the water of crystallization. The theory of this preparation is not well understood, and in general there is a considerable waste of the volatile alkali, for all that is added to redissolve the copper, seems to be afterwards evaporated. This objection applies with more force to the usual method of preparing it in the humid way. The most effectual, but the most expensive, mode of preparing it, is to precipitate the copper from a solution of its vitriol by means of ammonia, adding more of the latter till the copper is redissolved. This solution must be concentrated by evaporation, and then an equal quantity of alcohol added, which occasions a separation of silky blue crystals. In the cuprum ammoniacum there is evidently some portion of sulphuric acid, and the other ingredients are an oxide of copper and ammonia. It has been chiefly employed in epilepsies, and its virtue seems to be increased by the addition of the oxide of zinc. We know not this can produce any chemical change on either, yet, when combined, each may be given in a larger dose.

CUR. POST. An abbreviation of eura posteriores, the frequent title of a second part, or supplement.

CUR'A AVENA'CEA. A decoction of oats and succory roots, with a little nitre and sugar. It was formerly used as a common drink in fevers.

CUR'CAS. (See RIGINOIDES, under CATAPUTIA MINOR.) Also an edible root, probably of a species of arum.

CUR'CUMA, (from the Arabic term *carkim*). TURMERIC. *Crocus Indicus*, *terra marita*, *cyperi genus ex Indiâ*, *cannacorus radice croceo*, *manjella*, *kua*, *kaha*; by the Indians, *borri-borri*; by the Portuguese, *saffran de terra*; the Arabians call every root of a saffron colour by this name, *curcuma*. There are two species, the long and the round rooted; but the first is the best, and chiefly used. It is the *curcuma longa* Lin. Sp. Pl. 103. INDIAN LONG ROOTED TURMERIC.

The root is the only part in use; brought from the East Indies; small, tuberous, and knotty; externally greyish coloured, but internally of a deep lively yellow tending to red. It hath a slight aromatic and bitterish taste, and somewhat disagreeable smell. It gives out its virtues both to water and to spirit; by distillation with water, a small quantity of essential oil is obtained; and from the remaining decoction a bitter extract is procured by evaporation. The spirituous extract retains nearly the whole virtue of the root.

It has been thought a powerful remedy in obstructions of the viscera, particularly the abdominal; in icteric and uterine disorders. The dose may be from a

scruple to a drachm, but it is now very rarely used. The powder is often mixed with yellow peas, ground fine; the roots should be chosen of the largest size, fresh, compact, heavy, not easy to break, of a lightish yellow without, and a deep reddish yellow within.

It is chiefly consumed by the dyers. See Lewis's Mat. Med. Neumann's Chemical works.

CURD. See CASEUS and LAC.

CURIME'NTOS. The Portuguese appellation of some pains in the limbs, which are relieved by a warm bath, made with an astringent bark produced in the Brasils.

CURMI, (from *κεραυ*, to mix.) A drink made of barley, which is used instead of wine; such a liquor is employed in Iberia and Britain, which is prepared of wheat. (Dioscorides.) It is not difficult to recognise in this description our beer or ale; perhaps our white (wheat) ale.

CUR'SUMA, or CURTUMA. See CHELIDONIUM MINUS.

CURSU'TA. See GENTIANA PURPUREA.

CUR'TA, (from *curto*, to mangle). See COLOBOMATA.

CURU'RU. See BUFO.

CURU'RU A'PE. (Indian.) A scandent tree which grows in Brasil, and bears pods with seeds like beans: these seeds destroy fish, and produce intoxication in the inhabitants; the Omaguas of Brasil. It is the *paulinia curruru* of Lin. Sp. Pl. 524; or rather the *c. pinnata*, 525.

CURU'TU PA'LA. (Indian.) A shrub which grows in Malabar. The bark of the root boiled in water cures a diarrhœa; boiled and taken with it, a dysentery. *Tabernæmontana alternifolia* Lin. Sp. Pl. 308.

CUSCU'TA. *Cuscuta major*, *cassuta*, *epithimum*. DODDER, and DODDER OF THYME. The *cuscuta Europæa* Lin. Sp. Pl. 180,  $\alpha$  and  $\beta$ . It is of the number of plants called parasitical; it hath no leaves; grows on thyme, and consists of a number of slender juicy filaments, producing small heads of white or reddish flowers, followed by roundish capsules full of minute seeds. A large kind, known by the name of HELL WEED, is common on heaths, upon furzes and nettles. This hell weed destroys the vegetables which afford it nourishment, whence its name: it is also called *diaboli intestina*, the DEVIL'S GUTS.

Dodders are found on almost all plants; supposed to partake of the virtues of those on which they grow. They are hardly known in practice; but recommended as a remedy for rheumatism and gout; as aperitives, antiscorbutics, and gentle laxatives.

CUSPIDA'TUS, (from *cuspis*, a point or spear). POINTED. In botany the term regards the apex only, when the leaves have the apex sharp like a spear, or terminating in a bristly point. Some of the teeth are called *cuspidati*. See DENTES.

CU'SPIS, (from *caspiæ*, Chaldean, a shell or bone, with which spears were formerly pointed). Properly the point of a spear: but it is applied to the glans penis; and is also the name of a bandage.

CU'STOS O'CULI. An instrument to preserve the eye in an operation.

CUTAMBULI, (from *cutis*, the skin, and *ambulo*, to walk). A name of some worms either under the skin or upon it, which, by their ereeping, cause uneasiness and pain.

**CUTANEI MORBI.** If cutaneous diseases have been imperfectly, and with too little discrimination, described or considered by the practical physician, they have claimed a large share of the attention of nosologists, in whose systems each blemish on the skin has been magnified into a genus of disease. We cannot help smiling when to the last of the Linnæan genera in his nosology, which is only a *freckle*, the following pathetic exclamation is added:

Hei mihi! tot mortes homini quot membra, malisque  
Tot sumus infecti, mors ut medicina putetur.

In one view, the attention of nosologists to these diseases was properly employed, and, above all, the luminous terseness of the Linnæan language, viz. for the purpose of distinction; yet, were criticism our object, we could show that both Linnæus and Sauvages have failed in attaining this end; nor was accurate discrimination to be probably obtained without coloured plates, resembling those of Dr. Willan. Former authors gave little assistance: Mercurialis was too concise and imperfect; Plenck often obscure and inconsistent; Lorry, in his quarto volume, superficial and indistinct; and the ancients imperfect, confused, and inaccurate in their descriptions. In fact, previous to the appearance of Dr. Willan's work, our best assistant was Sauvages, in his larger work on nosology.

As we, in general, approve of Dr. Willan's arrangement, we shall first explain it, with his own remarks, so far as he has proceeded, adding those in the orders which have not appeared, that their arrangement suggests; after which we shall subjoin what appears to us an improved order, and an outline of the pathology of those complaints: the latter attempt, we believe, is new, and therefore, we trust, its imperfections will be excused.

Dr. Willan's orders are natural ones, viz. pimples, scales, rashes, vesicles, pustules, tubercles, and spots. The arrangement of these orders is of little importance; yet it has been suggested that it would have been more correct to have placed those first in which the protuberance was inconsiderable, and to have proceeded according to their increasing magnitude, as spots, rashes, pimples, scales, vesicles, pustules, and tubercles. Perhaps it would be still better, keeping this idea at the same time in view, to divide them into febrile and not febrile; including in the first class, pimples, pustules, vesicles, and rashes, and the others in the second. As the genera are introduced by Dr. Willan, this arrangement is not perfectly correct; but we shall employ it as more suitable to our pathological enquiries.

The pimples are styled *PAPULÆ*: they are small elevations of the skin, with an inflamed basis rising to a point, with either no, or a very imperceptible, fluid. When any fluid is present, it is serosity, sometimes peculiarly acrid, and never becomes purulent, but occasionally desquamating in branny scales. The genera included by Dr. Willan in this order are, the *strophulus* (the red gum, a vulgar corruption of the red gown, from the generally diffused colour); the *lichen* (the eruption in the spring, or from heat); and the *prurigo*, or the pimples which arise with general itching. The term pimples, or the equivalent appellation in different languages, has been employed with little accuracy. In our author's definition they are properly and strictly limited;

perhaps too strictly. The *prurigo* he has not, we think, properly defined. It is an itching of the skin, with small papulæ, seldom discoloured, with very slight fever, and without contagion. All these genera are connected with a febrile state of the constitution.

In the *PUSTULES* which follow, the little inaccuracy of which our arrangement is liable appears more conspicuous. Few are febrile diseases; but the itch, in its appearance, connects this order with the pimples, and the introduction of variola reduces it to the febrile complaints: nor, indeed, is the tinea wholly free from the suspicion of being originally a febrile indisposition.

The genera are, *scabies* (itch); *impetigo* (a running scab); *ecthyma* (an ulcerated tetter); *horriigo* (scald head); and *variola* (small pox). The itch, certainly, at times degenerates into the impetigo; and sometimes, in a secondary chronic state, forms distinct pustules.

The *VESICULÆ* contain the following genera, viz. the *varicella*; the *pemphigus*; the *pompholyx*; *miliaria*; *erysipelas*; *herpes* (shingles); *eczema* (heat eruption); and *aphtha* (thrush). There may be some doubt of the propriety of admitting aphtha as an affection of the epithelion, though it be a continuation of the skin. In that case, syphilis, cynanche maligna, and mercurial sores, should have a place as cutaneous diseases. In this order the genera are arranged according to the magnitude of the vesicle, except in the case of the varicella, to connect this with the former order. Each, except perhaps the eczema, is preceded by fever, as we shall show under the different heads. In the last fasciculus, we perceive that Dr. Willan has made some alteration in his arrangement, by including the erysipelas, the pemphigus, and the pompholyx, in a separate order, which he styles *BULLÆ*; but it is unnecessary to notice it particularly, as it does not materially alter our present views.

The *RASHES, EXANTHEMATATA*, contain the *urticaria* (nettle rash); *rubeola* (measles); *scarlatina* (scarlet fever); *roseola* (rose rash); *purpura* (scorbutic rash); *erythema* (red rash); and the *iris* (the rainbow rash). This, with the exception of the urticaria, whose vesicles sometimes rise above the skin, and might, perhaps, be with propriety arranged in our author's new order, bullæ, form a truly natural association.

The cutaneous diseases not attended with fever, are the *MACULÆ* (spots); *SQUAMÆ* (scales); and *TUBERCULA* (tubercles). The first contains those little insignificant deviations which do not constitute diseases; the second are disgusting and obstinate complaints; and the tubercles are often the most frightful masses.

The genera of the order *MACULA* are, *ephelis* (freckles); *nævus* (marks supposed to be the effects of the mother's longing); and *spilus* (a mole).

The genera of the *SQUAMÆ* are, the *lepra* (the true leprosy of the Greeks); *psoriasis* (the scaly tetter); *pitiriasis* (the dandriff); and *ichthyosis* (the fish skin). These are, perhaps, only forms of the true lepra.

The *TUBERCULA* are, *verruca* (a wart); *molluscum* (the small soft wen); *vittiligo* (soft smooth tubercles); *acne* (stone pock, the red tuberculated face); *lupus* (noli me tangere); *phyma* (boils or carbuncles); *frambæsia* (yaws); *elephantiasis* (Arabian leprosy).

We shall add what we consider an improved arrangement of these diseases; but should we err in thinking it such, it will detain the reader for a short time only.

A. *Febrile cutaneous diseases.*

1. PAPULÆ. *Gen.* PRURIGO LICHEN STROPHULUS.
2. EXANTHEMATA. RUBEOLA, SCARLATINA, ROSEOLA, PURPURA, ERYTHEMA, IRIS.
3. VESICULÆ. VARICELLA, MILIARIA, ERYSIPELAS, HERPES, ECZEMA, APHTHA.
4. PUSTULÆ. SCABIES, IMPETIGO, ECTHYMA, PORRIGO, VARIOLA, FRAMBÆSIA.
5. BULLÆ. URTICARIA, PEMPHIGUS, POMPHOLYX.

B. *Not febrile.*

1. MACULÆ. *Gen.* EPHELIS, NÆVUS, SPILUS.
2. SQUAMÆ. LEPRO, PSORIASIS, PITYRIASIS, ICTHYOSIS.
3. TUBERCULA. VERRUCA, MOLUSCUM, VITILIGO, ACNE, LUPUS, PHOMA, ELEPHANTIASIS.

Cutaneous diseases of the febrile kind often depend on the discharge of some morbid, often a specific, cause; the slight cutaneous affections occasionally appear to be only irritation communicated from the stomach. In some instances the white of an egg, in others, fish poison almost immediately after being swallowed, certainly long before it can have entered the mass of blood will produce papulæ. A proof of its not being owing to any deprivation of the animal fluids is, the eruptions being removed on evacuating the stomach. When owing to poison in the blood, and fever is excited in consequence, the copiousness and violence of the eruption are greatly mitigated by the regulation of the febrile state. If the fluids are forcibly propelled, and carried to the exhalants, so as to pass off in the form of sweat, either from the fluid form or the rapidity of the secretion, a portion is stopped by the cuticle, and inflammation is the consequence. We can easily conceive, as in the case of miliaria, where no poison probably exists, that copious sweating in the irritable state of the arterial system, which occurs in puerperal cases, may occasion eruptions; and we consequently find that, by a duly regulated temperature, this inconvenience can be avoided. In small pox, where a specific poison really exists, the eruption can be always mitigated or even occasionally prevented, by similar measures, viz. remedies peculiarly adapted to lessen the fever. In these cases, the exhalants, which open under the cuticle, convey the fluids in no greater quantity than the pores of this inorganic membrane allow to pass; so that, though the acrimony is occasionally perceptible by a little prurigo, or by the smell, no pustules inflame or suppurate.

It was not without design that we mentioned the form of the fluid discharged; for in almost every instance, gentle perspiration appears better adapted to preserve health and remove diseases than sweating. The form of gas may be chemically more suitable to the morbid cause, than that of a fluid; and it is certainly better adapted to transude through the cuticle, both from its attenuation, and the gentleness with which it is conveyed.

Though we have pointed out, in general, the surface as the channel by which the cause is evacuated, yet there is a peculiarity in the order exanthemata, and in one genus of the vesiculæ, if indeed it be admitted, we mean the aphtæ, viz. that the matter is carried to other membranes: in the two first genera, for instance, to the Schneiderian membrane and the throat; and, in the last, to the membranes of the brain; for erythema differs only

from erysipelas in form. The small pox virus is sometimes poured on the tunica conjunctiva, sometimes on the throat, and the villous coat of the intestinal canal; but this is not its usual or natural outlet.

The pustulæ we have allowed not to be always febrile; yet they are often so, though the ecthyma and variola are obviously diseases of this kind: and the former includes the phlegmous. The scabies, though not febrile, has this peculiarity, that it is excited to action by warmth and a more generous diet; but the operation of these existing causes we cannot now examine, until the cause itself is more clearly understood. The existence of an animalcule, producing the diseases, has been lately denied. When, however, the itch has been repelled rather than cured, its form, on its return, is very generally pustular.

The kind of fever in these cutaneous diseases greatly differs. It is inflammatory or putrid, continued or remittent. In the bullæ it is generally remittent. For this variety no adequate reason can be assigned: but the continued form of fever is generally observable in those eruptions where the poison is of a specific kind; the remittent form seems rather suited to the sporadic or accidental eruptions.

Several diseases concur in their general nature with the cutaneous. The nearest is dysentery, which greatly resembles them in their pathology and cure. Epidemic diarrhœas from cold are not very different. Ulcerated throat, pertussis, and croop, are affections of the epithelion continued from the skin. But of these we must not now treat.

The cutaneous diseases not febrile are of two kinds, viz. affections of the cuticle, or of the parts beneath. The maculæ and squamæ are of the former kind; but the genera included under the first of these are not, as we have said, diseases. Mere pressure on the cuticle will produce squamæ, but the causes in general are different. They seem to arise from an acrimony often constitutional, which, however, has not always sufficient power to excite inflammation; or, more probably, they are the diseases of torpid habits little susceptible of inflammatory excitement. This acrimony, either natural or acquired, is gradually deposited under the cuticle till it rises in irregular masses, or, from the pressure beneath, assumes a scaly form. The porrigo might, perhaps, with propriety be referred to this order, except that, as a disease of the roots of the hair, its source is below the cutis.

The tubercles, we have said, are seated below the skin. The verrucæ are connected with the extremities of the nerves; but their origin is doubtful, and their cure uncertain. The other tuberculæ are enlargements of the sebaceous glands as the wens; depositions become morbid by stagnation, as the phymata; or effects of depraved fluids or broken constitutions, as the lupus and elephantiasis; to which the Italian disease, the pelagra, may be added. The tubercles of the elephantiasis are often most horrible in their appearance; and Sauvages has exhausted the *monstra horrenda informia ingentia* in the description. They occur, however, only in the decline of life, and are preceded by marks of a decayed constitution, or depraved fluids. The same appearances also precede the true lepra; but these considerations we must resume under their proper heads; q. v.

It will appear singular that we have referred frambæsia to the pustulæ. The disease is little known; and the best account of it, that of Dr. Adams, in the 6th volume of the Memoirs of the Medical Society, justifies the change.

CUTA'NEUS MU'SCULUS, (from *cutis*, the skin; belonging to the skin). See PLATYSMA MYOIDES.

CUTA'NEUM O'SSIS CO'CXYGIS LIGAMENTUM. It goes out anteriorly from the extremity of the os coccygis; is slender, and divides into two portions at the orifice of the anus, which run into the membrana adiposa, are inserted in the skin on each side of the anus by a kind of expansion, and continue to divaricate: they are lost on the sides of the perinæum.

CUTA'NEUS. See SPHINCTER ANI. There is also a nerve so called. See CERVICALES.

CUTA'NEUS INTE'RNUS NERVUS. It rises from the union of the seventh cervical, and first dorsal pairs, runs over the other brachial nerves, and passes down on the inside of the arm, between the muscles and integuments; it divides into two branches, which accompany one another as far as the inner condyle on one side of the vena basilica, being covered by the ramus medianus of that vein; then runs down towards the wrist, where it spreads, and on the beginning of the palm of the hand. The other branch passes backward along the integuments, and down to the little finger.

CUT'CH. See TERRA JAPONICA.

CUTICULA, (a dim. of *cutis*, the skin). The SCARF SKIN. The Greeks call it *epidermis*, because it is placed upon the true skin as a covering. It is more compact than the true skin, full of pores for the evacuation of what transpires through it from the body, though the best glasses do not enable us to discern them: it hath neither blood vessels nor nerves, therefore it is void of sense. Dr. Hunter thinks it an organised body, though its organization cannot be demonstrated; and there is not the slightest reason from its functions or diseases to consider it as such. The pores described by Leuwenhoeck have not been found by later observers. When abraded it is rapidly reproduced, and is greatly thickened by pressure, either external or from tumours below its internal surface.

The integuments, or the universal covering of the body, are the cuticle, the rete mucosum, the cutis, and the membrana cellularis: besides these, the old anatomists reckon the membrana communis musculorum, which does not exist; and the panniculus carnosus, which is only found in brutes. The rete mucosum is added by the moderns, and is found between the skin and the cuticle.

The cuticle is continued only over all the external parts of the body: in the cavities, as in the mouth, œsophagus, aspera arteria, intestines, &c. it becomes almost imperceptible, and not to be distinguished from the cutis vera. The external covering of these internal parts is called the *epithelium*; and the surface is rendered irregular by innumerable papillæ. No nerves nor vessels can be demonstrated to exist in the true cuticle.

In examining the pores, the cuticle seems to insinuate itself into them, to complete the excretory tubes of the cutaneous glands. The fossulæ of the hairs have likewise the same productions of the cuticle, and it seems to give a sort of coat to the hairs themselves.

The best method of separating the cuticle for examin-

ation is to macerate it in water, or to suffer some putrefaction to take place.

The cuticle is a medium betwixt the skin and the subjects of feeling, and moderates the impressions, which, without it, would be too painful. It is also said to moderate the perspiration, which, without it, would be too copious. This, however, is hypothetical. It seems to be a sheath which, in some degree, compresses the whole body, and gives a tone to the extreme vessels. To its relaxation the effects of warm bathing, a moist or a humid atmosphere, have been attributed. Yet, as a simple solid, it can be but inconsiderably contracted by cold or expanded with heat; and though we cannot deny it some power as a counterpoise to the distention of the subcutaneous vessels, that power is probably trifling.

The cuticle is very incorruptible, even when the subjacent parts are destroyed by sphacelus; and suffers the effect of caustics to act on the subjacent parts without itself being destroyed.

The colour of the cutis differs in different persons, and also in different parts of the same person; but it is owing to the difference in the rete mucosum that complexioners are so opposite to one another. See Edinburgh Med. Essays, vol. iv. page 79.

In the second volume of the Medical Museum is a remarkable instance of a young man losing the use of his hands, by the cuticle being thickened and hardened in an extraordinary degree. He was a dyer, and by frequently cleaning brass wire in the mixture, which consists of the oil of vitriol, tartar, and alum, this complaint was gradually produced. His hands were quite stiff from the hardness of the cuticle; and on endeavouring to straighten the fingers by force, blood started from every joint. As the acid seemed to contribute much to the disease, an emollient liniment, with equal parts of olive oil and aqua kali, was ordered. After a few days one half of the aqua kali was omitted, and the yolks of two eggs added. By this means the hardened cuticle began to peel off; a new flexible one appeared underneath; he began to have some use of his fingers; and, after little more than two months, he obtained a perfect cure.

CUTICULA'RIS MEMBRA'NA, (from *cuticula*). See DURA MATER.

CUTICULO'SUS. See SPHINCTER ANI.

CUTILLÆ. Certain cold fountains in Italy, mentioned by Celsus and Pliny, which were used in baths.

CUT'IO, (a *cutis duritie*, from the hardness of its skin). See ASELLI.

CUT'IS, (from *κύβω*, to cover with a hide, or from *cutan*, a covering; Chaldean). The SKIN. It is called by Herodotus, *anthropie*. It is a strong, thick, universal covering of the external parts of the body, immediately above the adipose membrane. It is composed of a close texture of fibres of various kinds, and of veins and arteries, variously disposed: where there are large orifices, it is gradually lost. Its inner surface is moulded upon the outer surface of the membrana adiposa, whose membranous part produced, seems to form the skin.

The skin, on its outside, is unequal: this is occasioned by the miliary glands, and the bulbs of the hair. It is naturally contracted; but when it is swelled, it is smooth. Upon its surface we observe the papillæ pyramidales, which are longer in some parts than in others, as in the fingers, where they are called *villi*. They appear in rows, each having two ranks contiguous, and are

the organs of touch. Opposite to the joints the skin is thin, and formed into plicæ, to admit of a free motion. Its whole surface, outwardly, is covered with the rete mucosum, and the cuticle.

The skin is thickest between the shoulders, and on the back part of the neck. Dr. Hunter says, that when the skin is once destroyed it is never regenerated, but the edges stretch considerably to form a covering: after that, a cicatrix, which is hardened flesh, completes the healing. The loss of substance is discovered by injections.

The outer surface is furnished with small eminences, called *papillæ pyramidales*, and the inner with the milary glands. Fewer papillæ appear on the skin of the belly than elsewhere: the anterior portion of it is not only thinner and more compact than the posterior, but it may naturally be very much increased in breadth, to an extraordinary degree, without losing in thickness what it gains in breadth; and it is generally more difficult to pierce the skin of the belly with pointed instruments than of the back.

Though the best glasses cannot assist us to see pores in the cuticle, the naked eye can discern them in the skin, which is the seat of many diseases. Dr. Willan's late publication on these, has superseded the works of all his predecessors on cutaneous diseases of the skin.

**CUTIS ANSERINA.** When from cold, fear, or terror, the skin is contracted, the bulbs of the hair are conspicuous, and the surface resembles that of a newly plucked goose.

**CU'TT.** See **TERRA JAPONICA.**

**CY'AMOS ÆGYPTIACUS.** See **FABA ÆGYPTIACA.**

**CY'AMUS,** (from *κυω*, to bring forth; from its fecundity). See **FABA.** It also signifies a wood louse in the form of a bean. See **ASELLA.**

**CY'ANUS ORIENTALIS MAJOR MOSCHATUS,** SWEET SULTAN, OR SULTAN FLOWER. It is slightly cordial. *Centaurea moschata* Lin. Sp. Pl. 1286, *α.*

**CY'AR,** (from *κω*, to pour out). Properly, the eye of a needle; but it is used to signify the orifice of the internal ear. See **AURIS.**

**CYA'SMA.** Brown spots in the lips, forehead, and hands of pregnant women.

**CYATHIFORMIS,** (from *cyathus*, a cup, and *forma*, likeness). In botany it means shaped like a cup, that is partly cylindrical, but expanding towards the top.

**CYATHISCUS,** (from the same). The hollow part of a probe, formed in the shape of a small spout, as in an ear-picker.

**CY'ATHUS,** *κυαθος*, a CUP, (from *χυειν*, to pour out). It was a common measure among the Greeks and Romans, both of the liquid and dry kind; equal to an ounce, or the twelfth part of a pint. The sextans was two ounces; the quadrans, three; the triens, four; and were named from the portion of a pint they contained. The quincunx was five ounces; the semis, six; the septunx, seven; the bes, eight; the dodrans, nine; the dextans, ten; the deunx, eleven; the as, sextarius, or cotula, twelve. The cyathus was made with a handle like our punch ladle. The Romans were used to drink as many cyathi as there were muses; also as many as there were letters in their patron's or their mistress's name. Pliny and Galen say, that a cyathus of the Greeks weighed ten drachms;

though the latter elsewhere observes, that a cyathus contains twelve drachms of oil, thirteen drachms and one scruple of wine, water, or vinegar, and eighteen drachms of honey. Among the Veterinarii, the cyathus contained two ounces. The modern cyathus is  $\frac{3}{4}$  i.  $\beta$ .

**CY'BITOS.** See **CUBITUS.**

**CYBOIDES.** See **CUBOIDES.**

**CY'CAS CIRCINALIS** seu **I'NDICA.** See **PALMA JAPONICA.**

**CYCE'ON,** (from *κυκαω*, to mix; also *cinnum*, or *cinnus*). It is a mixture, of the consistence of pap, made with wine, honey, flour, and cheese; perhaps the macaroni of antiquity. This name was given to some ptisans; and to a kind of salad in which cheese was mixed. See also **CENUS ANTHINOS.**

**CY'CIMA,** (from the same; so called from the mixture of the ore with lead to form litharge). See **LITHARGYRUM.**

**CYCLA'MEN, EUROPE'UM,** (from *κυκλαω*, to surround; from the spiral coiling of its leaves and stalk). See **ARTHANITA.**

**CYCLI'SCUS,** (from *κυκλος*, a circle). See **TROCHISCUS.** Also an instrument formerly used in the operation of the trepan.

**CYCLO'PION.** The WHITE OF THE EYE, (from *κυκλωω*, to surround, and *ωψ*, the eye). See **ADNATA.**

**CY'CLOS.** A CIRCLE. See **BUCCÆ** and **ORBITA.**

**CY'CLUS METASYNCRITICUS.** It is a long protracted course of remedies, persisted in for restoring health.

**CYCNA'RION,** (from *κυκνες*, a swan). A collyrium mentioned by Galen and P. Ægineta, from its colour resembling that of a swan.

**CY'DAR.** See **STANNUM.**

**CYDER,** a fermented liquor from the juice of apples. It runs so quickly into fermentation that much care is necessary to check the process, which would otherwise soon render it acid. When in a good state, it is a very wholesome drink, though accused of producing rheumatism. Cyder drinkers are generally thin, but firm and muscular; certainly subject to rheumatism, and occasionally to gout; but, on the whole, healthy and long lived. The sweet cyders of Herefordshire are less wholesome than the strong, more pungent, cyder of Devonshire.

Cyder, when made early, of unripe fruit, is sharp and acrid; apparently able, without any suspicion of lead, to occasion the colica pictonum. The poison of this metal, however, often impregnates, from accident or design, this otherwise wholesome beverage; and the most fatal colics and palsies are the consequence.

**CYDERKIN,** a small cyder made by infusing the mock in water, and afterwards pressing. It is weak, and must be drunk immediately. From pears it is called *perkin*, and is prepared in the same way.

**CYDONA'TUM,** (from *cydoneum*, a quince). A preparation of quinces with an addition of aromatics, described by P. Ægineta.

**CYDO'NIA,** (from *Cydon*, a town in Crete, where they grew). The QUINCE TREE; also called *cotonea*, and *malus cydonia*. It is the *pyrus cydonia* Lin. Sp. Pl. 687. The WILD QUINCE TREE.

The quince tree is low, a native of the rocky banks of the Danube, and common in our gardens. Its fruit resembles, in shape, round pears; hath an agreeable and

strong smell, an austere and acid taste; and its expressed juice, taken in small quantities, is cooling and restringent, useful in nauseas, vomitings, nidorous eructations, as well as some kinds of diarrhœas: by boiling, it loses its astringency. The seeds abound with mucilage, which they yield to boiling water. One drachm makes six ounces of mucilage, resembling in consistency the white of egg, recommended in aphthous affections, and excoriations of the mouth and fauces; though that of the simple gums appears at least equally efficacious. It is the most agreeable of all the mucilages, but is apt to mould in a short time.

The London college directs the following mucilage of quince seed:

Take of quince seed, a drachm; distilled water, eight ounces: boil with a gentle fire, till the water thickens; then strain through a linen cloth.

Formerly a syrup was made of the juice of the fruit, and a conserve, called *marmalade*, *jelly*, *miva cydoniorum*, or *diacydonium*; but it is now an article of confectionary only. See Lewis's Mat. Med. Raii Hist.

CYDONIA EXOTICA. See COVALAM.

CYEMA. See CUEMA.

CYGNUS REGINÆ. A collyrium described by Ætius.

CYLICHNE, (from κυλίχ, *a cup*). A small vessel or box for holding medicines; a GALLI-POT, or PILL-BOX.

CYLINDRUS, (from κλινω, *to roll round*). The CYLINDER. A tube, equal in diameter from top to bottom. The fruits of plants are termed cylindrical, when they resemble a column. Martyn says, it is applied to stems, and some leaves, which are round, or rather without angles; but many times longer than they are thick. This, however, is more properly expressed by Columnar, because they are not of the same diameter from top to bottom. The term is applied to the calyx, to the style, and to the spike; as well as to masses of plaster. See MAGDALEONES.

CYLLOS, (from κολλω, *to make lame*). In Hippocrates, it a kind of luxation bending outwards, and hollowed within. Such a defect in the tibia is called *cyllosis*, and the person to whom it belongs is called, by the Latins, *varus* or *blæssus*, and is opposed to *valgus*.

CYLLO'SIS. See CYLLOS.

CYMA, κυμα, *fetus*, (from κυω, *to bring forth*).

CYME. It properly signifies a sprout or tender shoot, particularly of the cabbage. Linnæus explains it to be an aggregate flower, composed of several florets, sitting on a receptacle, producing all the primary peduncles from the same point, but having the partial peduncles scattered or irregular; all fastigate, or forming a flat surface at top. The cyme is either naked or with bractææ. Flowers disposed in a cyme are called *cymose flowers*: hence *cymosæ*, the sixty-third of Linnæus's natural orders in *Philosophia Botanica*.

CYMBÆ OS, (from *cymba*, *a boat*; so called from its supposed likeness to a skiff). See SCAPHOIDES OS.

CYMBALARIA, (from *cymbalum*, *a cymbal*; from the resemblance of its leaves to an ancient cymbal; also called *linaria*). IVY-LEAVED TOAD FLAX, or IVY WORT. It grows on old walls in Italy and Switzerland; and hath the same virtues as the navel wort. See ANDROSACES.

VOI. I.

CYMBALA'RIS CARTILA'GO. See CARTILAGO CRICOIDES.

CYMBIFO'RME, (from *cymba*, *a boat*). See SCAPHOIDES.

CY'MIA. See CARORA.

CY'MINUM, (Arab. *kumin*). See CUMINUM.

CYMO'SÆ. See CYMA.

CYNA'NCHE. See ANGINA.

CYNA'NCHICA MEDICAME'NTA. Medicines appropriated to the cynanche.

CYNA'NTHEMIS, (from κυων, *a dog*, and ανθεμος, *a flower*; because dogs are said to eat it). See CHAMÆMELUM FETIDUM.

CYNANTHRO'PIA, (from κυων, and ανθρωπος, *a man*). A kind of melancholy delirium, in which the persons affected believe they are changed into dogs. Sometimes the term for *hydrophobia*.

CY'NARA SCOLYMUS. See CINARA.

CY'NCHNIS. (Greek.) A small vessel to hold medicines.

CY'NICUS, (from κυων, *canis*). CANINE. Certain convulsions are called *cynic spasms*. See SARDONICTS RISIS.

CY'NIPHES, (from the Hebrew word *cnis*). FLIES or GNATS. Van Helmont.

CY'NNIA. See CARORA.

CYNOBO'TANE, (from κυων, *a dog*, and βοτανη, *a herb*). See CHAMÆMELUM FETIDUM.

CYNOCO'TANUM. See ACONITUM.

CYNOCO'PRUS, (from κυων, *a dog*, and κοπρος, *dung*). See ALBUM GRÆCUM.

CYNOCRA'MBE, (from κυων, *canis*, κρεμμυδι, *cabbage*; because dogs are said to eat it as a cathartic.) See MERCURIALIS, SYLVEST. and HIPPOMANES.

CYNOCY'TISIS, (from κυων, *canis*, and κυτίσις, *the cytusus*; because it cures the distemper of dogs). See CYNOSBATO'S.

CYNODE'CTOS, from κυων, *a dog*, and δακνω, *to bite*). Bitten by a mad dog.

CYNODES, (from κυων, *a dog*). CANINE.

CYNODE'SMION, (from κυων, *membrum virile*, and δειω, *ligo*). A ligature by which the prepuce is bound upon the glans; or the lower part of the prepuce.

CYNODO'NTES, (from κυων, *a dog*, and οδους, *a tooth*). See CANINI DENTES.

CYNOGLO'SSUM, (from κυων, *a dog*, and γλωσση, *a tongue*; from its resemblance). HOUND'S TONGUE.

CYNOGLO'SSUM MAJUS VULGARE CANINA LINGUA GREATER HOUND'S TONGUE. *Cynoglossum officinale* Lin. Sp. Pl. 192.

It is a biennial plant; producing, the first year, large, soft, tongue-shaped, long, pointed leaves: the second year, a thick branched stalk, with pointed leaves joined to it, without pedicles: on the tops of the branches are dark purple flowers, which are followed by four flat seeds: The root is oblong, and of a dark brown or blackish colour on the outside, but white within. It grows in shady places, and flowers in June.

The roots that grow in moist grounds have a rank, but not very strong, smell, like those of the narcotic plants, which in drying is mostly dissipated; those on dry ground have very little smell. In medicine is useless, but it has been employed adversus pediculos.

CYNO'LOPHA, (from κυων, *a dog*, and λοφος, *a protuberance*). The ASPERITIS OF THE UPPER

Q Y

DORSAL VERTEBRÆ: in dogs they are particularly eminent.

CYNOLYSSA, (from *κυν*, a dog, and *λυση*, madness). See LYSSA and HYDROPHOBIA.

CYNOMORON, (from *κυν*, a dog, and *μωρον*, a berry). See HIPPOMANES.

CYNOMY'A, (from *κυν*, a dog, and *μυα*, a fly). See PSYLLIUM.

CYNOPTICON. See DACNERON.

CYNOREXIA, (from *κυν*, and *ορεξις*, an appetite). See BOULIMUS.

CYNORRHODON, (from *κυν*, and *ροdon*, a rose). The DOG ROSE.

CYNOSBATUS, (from *κυν*, and *βατος*, a thorn). The BERRY OF THE DOG ROSE. *Canirubus*, *cynocytis*, *rosa sylvestris vulgaris*, and *inodora*. It is the *rosa canina* Lin. Sp. Pl. 631. The WILD BRIAR, or HIP FREE. It is one of the largest plants of the rose kind, a native of Britain, grows wild in hedges, and flowers in June. The fruit contains a sour sweetish pulp, which is made into a conserve, by adding to a pound of the pulp of the berries (hips) of double refined sugar twenty ounces.

The hips are to be split, and the hairy seeds carefully separated. When the fruit is mellowed by standing a few days, it must be pressed through a hair sieve, and to the pulp the sugar must be added. Ph. Lond. 1788. If this caution is not observed in pulping the fruit, the rough prickly matter enclosing the seeds may be retained in the conserve, which will occasion uneasiness at the stomach, an itching about the anus, and sometimes vomiting. Though formerly it was ordered in large doses, to correct acrid bile, sharp urine, heat in the stomach, and esteemed useful in many disorders, as dropsies, calculous complaints, dysenteries, hæmorrhages, &c. it is now considered only as agreeable to the taste, and principally used as a vehicle to more efficacious remedies. There is also a reddish green, spongy, hairy excrescence, made by small ichneumon flies, on the stalks of this tree, called *bedeguar*, celebrated for its astringent power; but it has not yet been sufficiently tried to speak with great certainty of its power.

CYNOSORCHIS, (from *κυν*, canis, and *ορχις*, a testicle; from the testicular shape of its root). See ORCHIS.

CYON. (See CANIS.) Also the inferior part of the penis and prepuce. See PENIS.

CYOPHORIA, (from *κυμα*, the fetus, and *φωρω*, to carry). See GESTATIO.

CYPARISSUS. See CUPRESSUS.

CYPERI GENUS EX INDIA. See CURCUMA.

CYPEROIDIS GRAMEN and CYPERI. See GRAMEN CYPEROIDES.

CYPERUS, (from *κυπαρος*, a little round vessel, which its root is said to resemble). A plant with vitreous leaves, and triangular stalks, bearing tufts of flowers on their top, followed by a triangular seed.

CYPERUS LONGUS, ODORATUS, Lin. Sp. Pl. 67. The ORDINARY SWEET CYPERUS, or ENGLISH GALANGAL. It hath a long slender root, crooked and knotted; on the outside of a blackish brown colour, and white within; grows in marshy places, and the English is equal to the foreign ones.

The root hath an agreeable aromatic smell, and a bitterish taste; both water and spirit take up its virtues:

by distillation a very small quantity of essential oil is obtained. It is chiefly noticed for its astringency.

CYPERUS ROTUNDUS, Lin. Sp. Pl. 67. *Creticus*, vel *syriacus*. ROUND ROOTED CYPERUS. The roots of this plant are about the size of walnuts, connected by fibres, rough, and rusty coloured on the outside, of a yellow white within. It is a native of the East Indies, and grows wild in some other countries. This sort is most noted for its aroma; but each species may be used indifferently. Raii Hist.

CYPERUS AMERICANUS. See SANCTÆ HELENÆ RADIX.

CYPERUS LONGUS ODO'RUS, &c. See CONTRAYERVA.

CYPERUS NILOTICUS vel SYRIACUS. See PAPYRUS.

CYPHI. A composition of sixteen ingredients, such as honey, raisins, cardamom seeds, &c.; much used in the Egyptian sacrifices, and the troches are called *trochisci cyphæos*.

CYPHOMA, CYPHOSIS, (from *κυφω*, to bend). A kind of gibbosity; a curvature of the spine of the back, when the vertebræ incline preternaturally outwards.

CYPIRA. See CURCUMA.

CYPRINUS. See CARPIO.

CYPRUS DIO'SCORIDIS et PLINII, (from the *isle of Cyprus*). See LIGUSTRUM INDICUM.

CYPSELE, (from *κυψελη*, a bee hive). See CERUMEN AURIS.

CYRÆNIA. The fæces of saffron infused in oil. Rulandus.

CYRBA'SIA. Properly the *tiara*, or CAP, worn by the Persian monarchs. Hippocrates uses this word in his Treatise of the Diseases of Women, when describing a covering for the breasts.

CYRE'BIA, (a corruption of *κυρβια folliculi fabarum*). The HUSKS OF BARLEY, or of other corn, which fall off while they are roasted, or soaked in water.

CYRENAICUS SAL. Produced in *Cyrene*. See AMMONIACUS SAL.

CYRENAICUS SUCCUS; applied to the juice of the lasepitium of the ancients, from the country where it most flourished, by Scribonius Largus, Paulus Ægineta, and Sanctorius. See ASAFÆTIDA.

CYRO'NES. See PHTHIRIASIS.

CYRSE'ON. See ANUS.

CYRTOIDES, CYRTO'MA. GIBBOSITAS. Any preternatural tumour or gibbosity, (from *κυρτος*, hump-backed). In Vogel's Nosology, it signifies a particular flatulent tumour of the belly.

CYRTONOSUS, (from *κυρτος*, curved, and *νοσος*, a disease). See RACHITIS.

CYSSAROS, (from *κυσος*, the breech). The ANUS, or RECTUM.

CYSSOTIS, (from the same). See PROCTALGIA.

CYSTEOLITHOS, (from *κυστις*, the bladder, and *λιθος*, the stone). See CALCULUS.

CYSTICÆ ARTERIÆ, (from *κυστις*, the bladder). The CYSTIC ARTERIES. The hepatic artery advances behind the ductus hepaticus towards the vesicula fellis, to which it gives two principal branches. These are called *arteriæ cysticæ*. See HEPATICA ARTERIA.

CYSTICÆ VENÆ, (from the same). A branch from the vena portæ ventralis. They run along the

Vesicula fellis, from its neck to the bottom; and as they are often only two in number, they are called *cysticæ gamellæ*.

CYSTIRRIA'GIA, (from *κυστις*, and *ῥέω*, to flow). Discharge of the blood from the urinary bladder; generally symptomatic.

CYSTICA'PNOS AFRICA'NA SCA'NDENS, (from *κυστις*, and *καπνος*, smoke; from its pods resembling a brown bladder). See FUMARIA ALBA.

CYSTICUS DU'CTUS, DU'CTUS VESICULARIS. The neck of the gall bladder is formed by the contraction of its small extremity; and this neck bending afterwards, produces a narrow canal called the *ductus*, and *meatus*, *cysticus*. It conveys the gall from the gall bladder to the duodenum.

CYSTICA ISCHU'RIA. See ISCHURIA.

CYSTI'DES. Encysted tumours, and those whose substance is included in a membrane.

CYSTIS. A BAG. It is applied to any receptacle of morbid humours (see CAPSULA,) and to the VESICA URINARIA; q. v. Many complaints of the bladder are derived from this term, compounded with some other words, as *cystitis*, *cystocele*, *cystorrhæa*, &c. &c.

CYSTINX. A small bladder.

CYSTI'TIS, CYSTIPHLO'GIA, (from *κυστις*, and *φλογεω*, inflammation). See INFLAMMATIO VESICÆ.

CYSTOLI'THICA ISCHU'RIA, (from *κυστις*, and *λίθος*, a stone). A suppression of urine from a stone in the bladder. See ISCHURIA.

CYSTOPHLE'GICA, (from *κυστις*, and *φλεσσω*, to strike). A suppression of urine from a blow on the bladder. See ISCHURIA.

CYSTOCE'LE, (from *κυστις*, and *κηλη*, a tumour). A hernia formed by the protrusion of the urinary bladder.

CYSTOCE'LE VAGINA'LIS. See COLPOCELE.

CYSTOPTO'SIS, (from *κυστις*, and *πίπτω*, to fall). The inner membranes of the bladder protruding through the urethra.

CYSTOPHLEGMA'TICA, (from *κυστις*, and *φλεγμα*, phlegm). A suppression of urine from abundance of mucus in the bladder. See ISCHURIA.

CYSTOSPA'STICA, (from the same, and *σπασμα*, a spasm). A suppression of urine from a spasm in the sphincter of the bladder. See ISCHURIA.

CYSTOTHROMBOIDES, (from the same, and *θρόμβος*, a coagulation of the blood). A suppression of urine from grumous blood in the bladder. See ISCHURIA.

CYSTOSPY'ICA, (from —, and *πυον*, pus). A suppression of urine from purulent matter in the bladder. See ISCHURIA.

CYSTOPRO'CTICA, (from — and *πρωκτος*, anus, or rectum). A suppression of urine from pain in the bladder, caused by indurated fæces, wind, inflammation, or abscess, in the rectum. See ISCHURIA.

CYSTOTO'MIA, (from —, and *τεμνω*, to cut). A cutting of the bladder in the operation for the stone. See LITHOTOMIA.

CY'THION. A collyrium mentioned by Celsus.

CYTINIFO'RME, CYTI'NUS, (from *κυω*, to produce; from its fecundity,) generally signify the flower of the true pomegranate; but sometimes the cups of flowers which expand after the same manner.

CY'TINUS HYPOCI'STIS. See HYPOCISTIS.

CYTISO GENI'STA. See GENISTA, SCOPARIA, and CAPPARIS, (from *cytissus*, the bean trefoil, and *genista*, broom; from having flowers like the *cytissus*).

CY'TISUS ALPI'NUS; also called *anagyris non fetida*. BEAN TREFOIL TREE. *Cytissus laburnum* Lin. Sp. Pl. 1041. The leaves are said to cool and discuss; a decoction of them is diuretic.

CY'TISUS SPINO'SUS; *acacia altera trifolia*, *cytiso-spartium aculeatum*. TREFOIL ACACIA. *Spartium spinosum* Lin. Sp. Pl. 997. Its juice is astringent.

CY'TISUS SCO'PARIUS VU'LGARIS. See GENISTA.

CYZICE'NUS. An epithet of a plaster commended by Galen for ulcers and wounds of the nervous parts.

## D.

## D Æ D

**D.** See VITRIOLUM.

DABU'RI. See ACHIOTL.

DA'CETON, (from *δακνω*, to bite). An epithet for such animals as injure by biting.

DA'CHEL, (Arab. *dekel*). See DACTYLUS.

DA'CNERON, (from *δακνω*, to bite). BITING. An epithet for a collyrium in Trallian; also called *oxydorcua*, and *cynopticon*.

DACRY'DIUM, (from *δακρυ*, a tear). See DIACRIDIUM.

DACRYO'DES, (from *δακρυ*, a tear). In Hippocrates it is a sanious ulcer.

DACRYO'MA, (from *δακρυναι*, to weep). A coalition of one or more of the puncta lacrymalia.

DACRYOPCE'OS, (from *δακρυ*, a tear, and *ποιεω*, facio). An epithet for substances which cause a flow of tears, as onions, &c.

DACTYLE'TUS, (from *δακτυλος*, a date). See HERMODACTYLUS.

DACTYLE'THRA, (from *δακτυλος*, a finger.) A machine shaped like a finger, and introduced into the stomach to excite a vomiting.

DACTY'LION, (from the same). WEB FINGERED.

DACTY'LIOS, (from the same). See TROCHISCI.

DA'CTYLON RADICE REPENTE. See GRAMEN DACTYLON.

DACTYLOTHE'CE, (from *δακτυλος*, a finger, and *τιθημι*, pono). So Paré calls an instrument which he used in some cases of injury done to the fingers.

DA'CTYLUS, (from *δεικνω*, to point out). The FINGER; and the fruit of the *palma dactylifera*, a DATE; called *dactylus* and *digitus*, from its likeness to a finger.

DA'CTYLUS PA'LMULA. *Palma major*, *palma dactylifera*; *phanix dactylifera* Lin. Sp. Pl. 1658; the GREAT PALM TREE, or DATE TREE. It is cultivated in the southern parts of Europe; its fruit is oblong, larger than an acorn, and includes a stone. The best dates are those which are soft, large, and not much wrinkled, of a reddish yellow colour on the outside, and a whitish membrane between the flesh and the stone. They are moderately astringent, particularly when unripe, yet are eaten as food in Africa. Galen calls the best dates, in Syria, *caryoti*.

DÆ'DALUS. QUICKSILVER. See ARG. VIVUM.

DÆDA'LEUS, (from *διδάλλω*, to work curiously). In botany it means exquisitely and curiously wrought.

## D A P

DÆ'DION *tædula*, (a diminutive of *dais tæda*, a torch,) a kind of pessary.

DÆMO'NIS. ORDURE. DUNG.

DÆMONOMA'NIA, (from *δαίμων*, *dæmon*, and *μανία*, madness). *Dæmonia*. The melancholy which is supposed to arise from the possession of demons.

DAIS. See TÆDA.

DAITI'DES, (from *δαις*, and *ειδος*, likeness). In Galen it means great torches; but it is usually applied to heads of garlic. See ALLIUM.

DALI'GTHRON. A name of the *thalictrum*. See SOPHIA.

DA'MA, (from *deima*, fear; from its timidity). FALLOW DEER; *cervus dama* Lin. The venison of a deer killed, when cool, differs much from that of one heated with exercise. The fibres of the first are harder, the flesh more tough, and less easily soluble in the stomach; but, in general, it is an alkaliescent, sapid animal, considered as a delicacy, and of easy digestion. (See ALIMENT). Medicinal virtues have been attributed to different parts. The recent blood, drunk immediately from the veins, hath been said to remove vertigo; the gall to be detersive, and take away films from the eyes; the liver hath been recommended in diarrhœa, the horns are of the same nature as those of the stag, and the fat or suet agrees perfectly with that of the same animal.

DAMASCE'NA PRU'NA NOSTRA'TA, (from *Damascus*, the place from whence they were brought). See PRUNA DAMASCENA.

DAMASCE'NÆ PA'SSULÆ, vel U'VÆ, (from the same). See VITIS.

DAMASO'NICUM and DAMASO'NIUM. See DORIA.

DAMNATA TERRA, (from *damno*, to condemn). See CAPUT MORTUUM.

DANAIS. (Greek). See CONYZA.

DAPHNE, (from *Daphne*, supposed in fable to have been converted into a plant of this kind). The BAY TREE. See LAURUS ALEXANDRINA.

DAPHNE GNI'DIUM. See THYMELEA MONSPELIACA.

DAPHNE LAURE'OLA. See LAUREOLA MAS.

DAPHNE MEZE'REUM. See LAUREOLA FEMINA.

DAPHNELÆON, (from *δαφνη*, and *ελαιον*, oil). The OIL OF BAY BERRIES. See LAURUS VULGARIS.

DAPHNI'TIS, (from its resembling the laurel). A name for the best pieces of cassia.

DAPHNOIDES, (from *δαφνη*, and *ειδος*, likeness). See LAUREOLA MAS.

DA'RATOS. UNFERMENTED BREAD. See PANIS.

DA'RCHEM, and DA'RSIN. See CINNAMOMUM.

DA'RSIS, (from *δαρω*, to excoriate). When the skin is divided and separated by the scalpel from the parts which are situated underneath, and often when one part is separated from another, the phrase *κατα δαρσιν*, was used.

DA'RTA. See HERPES and PRURITUS.

DA'RTOS, (from *δερμα*, leather). *Dartos*, a Greek name, derived from its raw or excoriated appearance, and not from its use in contracting the scrotum. (See Warner on the Testicles, p. 2.) One of the coats which forms the scrotum is called the *dartos muscle* and *corium*. Dr. Hunter asserts that no such muscle can be found; and Albinus takes no notice of it in his table. See SCROTUM.

DAS. See TÆDA.

DASY'MMA, (from *δαρμα*, rough). See TRACHOMA.

DA'SYS, (from the same). Dense, thick, close, or rough; an epithet for a tongue that is parched in a fever. Applied to respiration, it signifies a contracted breathing, as if the lungs had not room to expand; and those who suffer from it are called *cerchodes*.

DATISCA CANNABINA, Lin. Sp. Pl. 1469, has been recommended as a substitute for the bark, in the same doses.

DATU'RA, and DATYRA. (Indian.) See STRAMONIUM.

DAUCITES VI'NUM, (from *δαυκος*, the wild carrot). Wine in which are the seeds of *daucus*.

DAUCUS, (*απο του δαυσιν*, from its relieving the colic, and dispersing flatulencies). The CARROT, called also *carota*, supposed to be derived from *cara*.

DAUCUS ALSA'TICUS. See OREOSELINUM PRATENSE.

DAUCUS A'NNUUS MI'NOR. See CAUCALIS.

DAUCUS VU'LGARIS; called also *daucus sylvestris*, *pastinaca tenuifolia*, *staphilinus Græcorum vel sylvestris*. WILD CARROT, or BIRD'S NEST. It is the *daucus carota* Lin. Sp. Pl. 348.

DAUCUS CRE'TICUS; *myrrhis annua*, *daucus foliis fœniculi tenuissimis*, CARROT of CRETE. It is the *athamanta Cretensis* Lin. Sp. Pl. 352; but often brought from Germany. The best is large, fresh, sound, and of an acrid taste.

The wild carrot is common in many uncultivated parts of England, and flowers in June: in its cultivated state, this is the well known garden carrot. Carrots appear to contain, from experiment, a large proportion of saccharine matter, and consequently afford much nourishment, if well boiled; if eaten raw, they are very difficult in digestion, and pass through the bowels without suffering any considerable change. Raw carrots have been given to children as an anthelmintic, probably, on this account: in calculous complaints, the expressed juice, or decoction of the roots, has been recommended; and as gargles for infants in aphthous affections, or excoriations of the mouth: to cancerous and putrid sores, and to phagedænic ulcers, cataplasms of scraped carrot have been found useful, as they mitigate the pain, and abate the stench of such as are foul and offensive. The seeds are similar in their taste and

smell to those of the Cretan carrot, but weaker: they are, however, substituted for them; and, if infused in ale or wine, give out their diuretic, antiscorbutic, carminative, and lithontriptic virtues; at least, all which they possess. They are, indeed, slightly carminative and diuretic, but little more. Half a pound of the seeds may be infused in five or six gallons of ale, and a pint of the clear liquor drunk three times a day. The seeds of the wild carrot, which should be gathered in August, are said in many instances to have been useful in the stone and gravel, particularly in the latter, when accompanied with great pain and coffee coloured or bloody urine. Half an ounce of the seeds may be added to half a pint of boiling water, and the infusion drunk with sugar and milk, instead of tea, for breakfast, and again in the afternoon. Gouty people, who are afflicted with the gravel, are sometimes relieved by it in a few days; others do not perceive any sensible effect from it for some months, but have been afterwards rewarded for their perseverance: though Dr. Cullen says, that the seed has been employed for a considerable time, in large quantities, in calculous cases, without any apparent remarkable diuretic power.

DAUCUS SATIVUS. *Daucus carota* Lin. var. γ. The COMMON GARDEN CARROT. This root is in frequent use, and though it will not yield any grained sugar, it affords a great deal of a sweet juice, strongly nutritious. When boiled, it affords a tender, and not very flatulent, food. The roots, when scraped small, and made up into a poultice, take off the disagreeable smell which attends ulcerated cancers. The raw carrot may be scraped or grated, then made into a cataplasm with cold water, and applied to any fetid ulcers; or carrots may be boiled a sufficient time till they become soft enough to mash into a pulp. The raw carrots are, however, preferable. Turnips prepared the same way are said to answer a similar purpose. They are both to be applied immediately to the ulcer, without the intervention of any other substance. See Lond. Med. Obs. and Inq. vol. iv. p. 183, 358, &c. Lewis's Mat. Med.

DAUCUS MACEDO'NIUS. See APIUM MACEDONICUM.

DAUCUS MONTA'NUS. See OREOSELINUM, API FOLIO.

DAUCUS ODORA'TUS CRE'TICUS. See CUMINOIDES.

DAUCUS PEREGRI'NUS. See SELINUM MONTAN.

DAUCUS PETRO'SELINI vel CORIANDRI FOLIO. See BUNIUM.

DAUCUS SELENOIDES. See OREOSELINUM.

DAULO'NTAS FRU'TEX. An American shrub, which Lemery says possesses the properties of camomile, and its berries relieve asthmas.

DAUPHINY SAL. See GLAUBERI SAL.

DAU'RA. See HELLEBORUM NIGRUM.

DAVERI'DON. OIL OF SPIKE. See LAVENDULA LATIFOLIA.

DEAFNESS. See DYSŒCEA and SURDITAS.

DEARTICULA'TIO, (from *de* and *articulus*, a joint). See DIARTHROSIS.

DEASCIA'TIO, (from *de*, and *ascio*, to chide, as with a hatchet). See APOSCERNISMUS.

DEATH. When we contemplate the wonderful structure of the human frame, the varied form in which it is supplied with what is necessary to its perfect state,

the resources accumulated to obviate accidental wants, and the exertions of nature to supply every defect, we appear to be calculated for immortality. Disease, however, sometimes rapidly terminates the scene; but age, without its aid, undermines the vital and mental powers, and the wonderful machine of man sinks again into feeble infancy, and the mental imbecility of the same period, so as to be the shadow of his former self, the ruin of the once boasted structure.

To trace this change, it will be necessary to examine the progressive stages of life, as they affect the different parts of the system. In the circulation, we have found the arterial system strong in proportion to the venal, and gradually decaying in activity and power. In the nervous system, irritability lessens, and torpor succeeds; in the muscular fibres, the same torpor occasions their less ready obedience to stimuli and to volition. From all these causes the circulation languishes, the extremities become cold, the feeling is blunted, the veins filled, and the excretions sluggish. Ossifications take place in the arteries; and mortification, from this cause, closes the scene: the bronchial glands cannot propel their contents, and, occasionally, suffocation follows; the distended veins burst in the head, and the principle of life is at once overwhelmed. In other circumstances, the activity of the circulation languishes, the blood is confined to the larger vessels, and the heart can no longer contend with the increasing load; or the vital power is gradually sunk in sleep, and at last in death, assuming the form of a deeper slumber.

The *causes of death*, at an earlier period, are either the destruction of an organ essential to life; a total obstruction to the supply of nutriment; or a poison gradually introduced, either undermining the vital powers, or exhausting the strength, by the regularly returning paroxysms of hectic. In continued fevers we cannot distinctly see the action of either cause separately; but the most frequent is exhausted strength, or an oppressed brain.

The *signs of approaching death* are, a rapid and very small, scarcely distinguishable, pulse, cold extremities, clammy sweats, "a lack lustre eye," features sunk, the expression lost, and a hollowness particularly at the temples: the three last characters constitute the *facies Hippocratica*. These are all signs of a total loss of activity and power in the circulating and nervous systems.

In these different states, the mind seems to sink with the body; its powers decay *pari passu*: and when the medium through which the activity of the soul is manifested can act no longer, we cannot expect to find any further traces even of its existence. Yet at the period of its separation, we are told of brilliant mental exertions, of powers of intellect, not equalled in the best portion of existence. It has not been our fortune to see such intellectual animation. At the moment of death, anxiety for those we have loved will sometimes occasion apparently disproportioned exertions; and, as they were unexpected, they have been exaggerated. But in no instance could we ever detect the activity of mind independent of the body. To this temporary prison the soul is confined, till, by the destruction of the machine, its animating principle is emancipated, soaring probably in higher, and, we trust, more blissful, regions.

**DEBILITATES**, (from *debilis*, weak). Diseases from deficiency, as blindness, want of appetite, &c.

**DEBUS**. A medicine given against anger. *Paracelsus*.

**DEC**. The abbreviation of *decad*.

**DECA'MYRON**, (from *δεκα*, *ten*, and *μυρον*, an ointment). In Oribasius it is a composition made of ten aromatics, forming an ointment.

**DECAGYNIA**, (from *δεκα*, *ten*, and *γυνή*, a woman). **TEN STYLED**; the name of one of the orders of the *decandria*, comprehending those flowers which have ten styles, considered as the female organs of generation.

**DECANDRIA**, (from *δεκα*, *decem*, and *ανρ*, *vir*). The name of the tenth class of Linnæus's artificial system, comprehending all hermaphrodite flowers, with ten stamens or filaments in each flower, and one style. It is also the name of an order in the classes *monadelphica*, *diadelphica*, *gynandria*, and *diacia*.

**DECANTA'TIO**, **DECANTATION**, (from *decanter*, French). Pouring the clear liquor from a sediment. See **DEPURATIO**.

**DECIDE'NTIA**, (from *decido*, to fall down). It is an epithet affixed to some acute diseases, which are protracted beyond fourteen days, to the twentieth, sometimes to the fortieth day; hence diseases are called *acute per decidentia*, or *ex decidentia*. It also means a sudden falling down. See **CATAPORESIS**.

**DECIDUA**, (from the Latin, *de*, from, and *cado*, to fall). **FALLING**, fading once in the year; whatever falls away, as leaves of trees. In botany, deciduous plants are such as cast their leaves in winter. From this Dr. Hunter calls the spongy chorion by the names *decidua* and *caduca*. (See **ABORTUS**.) Dr. Hamilton observes that the membranes (speaking of those which contain the fœtus during pregnancy) consist, externally, of two layers of the spongy chorion, called *decidua* and *decidua reflexa*: internally, of the true chorion, and the amnion. They form a pretty strong bag, commencing at the edge of the cake, going round the whole circumference, and lining the internal surface of the womb. The membrana decidua, or that lamella of the spongy false chorion which is in immediate contact with the uterus, is originally very thick and spongy, and exceedingly vascular, particularly where it approaches the placenta. At first it is loosely spread over the ovum; and the intervening space filled with a quantity of gelatinous substance; but gradually becomes more and more attenuated, and approaches nearer to the interior lamella of the decidua, called *decidua reflexa*: about the fifth month the two layers come in contact, and adhere so as to become apparently one membrane. The decidua reflexa, in its structure and appearance, is similar to the former, being rough, fleecy, and vascular, on its external surface; internally, smoother, and perforated with a number of small foramina, which are the orifices of vessels that open on this internal surface. In advanced gestation it adheres intimately to the former membrane, and is with difficulty separated when the double decidua comes off entire; but the outer lamella more commonly adheres to the uterus after the placenta and other membranes are expelled, and is afterwards cast off with the cleansings. The decidua reflexa also becomes thicker and more vascular as it approaches the placenta; and is then blended with its substance, constituting the cellular or maternal part of the cake. The other, or more internal part, belongs to the fœtus, and is styled the fetal part of the placenta. The double

decidua is opaque, in comparison of the other membranes; the blood vessels are derived from the uterus, and can be readily traced into it. Dr. Hunter supposes that the double decidua lines the uterus nearly in the same manner as the peritonæum does the cavity of the abdomen, and that the ovum is inclosed within its duplication, as within a double night cap. On this supposition, the ovum must be placed on the outside of this membrane; which is not very easily comprehended, unless we adopt Signor Scarpa's opinion, and suppose it to be originally composed of an inspissated coagulable lymph.

Dr. Ruysch called this exterior coat the *tunica filamentosa*; more modern authors, the *false* or *spongy chorion*, consisting, as we have said, of two distinct layers. The portion which covers the ovum is a complete membrane, like the true chorion and amnios; but that which immediately lines the uterus is imperfect or deficient, being perforated with three foramina, viz. two small ones, corresponding with the insertion of the tubes at the fundus uteri; and a larger ragged perforation opposite to the orifice of the womb. See Dr. Hamilton's Outlines; Dr. Hunter on the Gravid Uterus.

DECIMA'NA, (from *decem*, *ten*, and *mane*, *morning*). An erratic kind of fever, which returns every tenth day; but such fevers are not observed, at least in this country.

DECLINA'TIO, (from *declino*, *to abate*). The decline of a disease. See LUXATIO.

DECLI'VIS, (from *de*, and *clivis*, *a hill*). See OB-LIQUUS DESCENDENS.

DECO'CTA, (from *decoquo*, *to boil away*), water that hath not been boiled, and is cooled by the help of snow. Decocta also signify decoctions, boiling different ingredients in water, and administering the liquor, strained, either when cold or hot, according to the nature of the substance boiled.

DECO'CTUM A'LBUM. See CORNU CERVI.

DECO'CTUM RU'BRUM. See CORNU CERVI.

DECO'CTIO, (from *decoquo*, *to boil away*). See COCTIO.

DECOLO'RES, (from *de*, and *color*, *colour*). Diseases which disagreeably change the colour of the skin.

DECORTICA'TIO, (from *de*, and *cortex*, *bark*). The separation of the outward coat from branches or seeds.

DECREPITA'TIO, vel CREPITA'TIO, (from *decrepito*, *to crackle*). The crackling noise which common salt makes when thrown on the fire, from the sudden separation of its water of crystallization.

DECUMBENS, (from *decumbo*, *to lie down*). DECUMBENT. In botany it is drooping, hanging down.

DECURRENS, (from *decurro*, *to run along*). DECURRENT. In botany it is applied to a leaf, when its basis extends downwards, below the proper termination of the leaf.

DECURSI'VUS, (from the same). DECURSIVE; when the bases of the lesser leaves are continued along the sides of the petiola.

DECURTA'TUS PU'LSUS, (from *decurto*, *to curtail*). A weak or a deficient pulse. If it fails, and revives by turns, it is called *decurtatus reciprocus*.

DECUSSA'TION. The crossing of nerves or muscular fibres.

DECUSSATUS, (from *decusso*, *to divide*). DECUSSATED. In botany it means growing in pairs and op-

posite, each pair being alternately on opposite sides of the stem.

DECUSSO'RIMUM, (from the same). An instrument to depress the dura mater after trepanning, quia decutit membranam, or from its extremity being grooved, decussatim.

DECOLLA'TIO, (from *decollo*, *to behead*). It is when a part of the cranium is cut off with the teguments in a wound of the head.

DEFECATIO. In chemistry, to free from fæces.

DEFECTI'VI, (from *deficio*, *to faint*). Synonymous with *adynamia*.

DEFECTIO ANIMI, (from the same). See LIPOTHYMIA.

DEFENSIVA, (from *defendo*, *to defend*). See CARDIACA.

DEFENSIVUM, (from the same). An epithet for some surgical topics which repel; or, in some authors, such as defend. Of this kind are external dressings. See Kirkland.

DEFERE'NTIA VA'SA, (from *defero*, *to convey*).

Immediately beneath the tunica albuginea are lodged the testicles, the tubuli of which run on to form the epididymis. They then become larger, unite, and form the vasa deferentia, which ascend in the spermatic cord behind the blood vessels; and having got through the abdominal rings, are reflected downwards, and passing on the back of the bladder, between that and the ureter, go on the inside of the vesicula seminalis, to its anterior end, where they unite with the vesicula; and, from the union of these with the vesiculæ seminales, two ducts are formed and continued, which gradually approaching each other, become contiguous at the notch, in the basis of the prostate gland, and terminate in a small duct on each side of the caput gallinaginis, in the urethra. At a distance from the vesiculæ seminales, the vas deferens is hardly capable of admitting an hog's bristle; but, as it approaches the vesicula, it grows larger both externally and internally, and becomes cellular and tortuous. The use of these vessels is to contain the sperm secreted from the blood, and to carry it into the spermatic vessels.

DEFI'XUS, (from *defigo*, *to fasten*; because it was supposed that every man thus defective was bewitched, or fastened by some charm). Impotent with respect to venereal desires.

DEFLAGRA'TIO, (from *deflagro*, *to burn*). See CALCINATIO.

DEFLORA'TUS, (from *de*, and *flos*, *a flower*). DEFLORATED. In botany it means having shed or discharged its flowers; in anatomy, the loss of virginity.

DEFLU'XIO, (from *defluo*, *to flow down*). A DEFLUXION. The flowing down of humours upon any inferior part, as in a catarrh. They are supposed to flow from the head.

DEFORMA'TIONES, and DEFO'RMES. Synonymous with *cachexiæ*; or any diseases occasioning external deformity of the body.

DEFRU'TUM, (from *deserveo*, *to grow cool*). See MUSTUM.

DEGLUTI'TIO, (from *deglutio*, *to swallow*). The act of SWALLOWING. In swallowing, the morsel is collected on the upper surface of the tongue, is squeezed against the bony palate, and then carries the palatum

molle backward and upward; the pharynx meets it, the tongue keeps close to the palatum molle, and by this action the epiglottis closes the rimula of the larynx. The bolus is consequently forced down the œsophagus. When it is carried into the stomach, it is propelled by the successive action of the circular fibres of the pharynx, which contract from above downwards; and for this reason, when the continuity of these circles is destroyed by an ulcer, the action of the œsophagus is impeded or destroyed. General debility in a similar way will impede swallowing, and it is not uncommon in nurses, when the child's wants are disproportioned to the supply. Hysteric affections will equally occasion the disease, not only from debility, but from the distention of the stomach with wind, which the action of the muscular fibres cannot conquer. The latter cause we suspect to be much more frequent than physicians have supposed. Independent of these causes, incapability of swallowing, called *acatoposis*, or a difficulty, named *dysphagia*, or *agglutitio*, may be occasioned by a thickening of the mucus in the œsophagus; indurations of the canal; a fungus in it; by spasms; foreign bodies sticking in their passage to the stomach; tumours pressing against the side of the œsophagus, either of the canal or neighbouring parts.

Mr. Warner relates a singular case of difficult swallowing, in which the œsophagus, besides being otherwise diseased, was ulcerated in its internal surface; which we shall relate to facilitate the distinction, and assist future practitioners in their prognostics. A young woman, aged twenty-five, had been afflicted with a difficulty in swallowing for some months; the sense of constriction was just below the back part of the cricoid cartilage. The part affected was easily discovered, by conveying down the throat a bit of sponge, fastened upon whale bone, which, though very small, could not be made to pass beyond it. She at length became incapable of taking any nourishment, and soon after died. After death, her neck was opened, and, upon taking out the œsophagus, it appeared considerably thickened, about an inch in length, just below the cricoid cartilage. Upon opening the œsophagus lengthways, its coats appeared so contracted in the diseased part, as to be only just capable of admitting a passage to a common probe. The internal coat of the œsophagus was in part ulcerated, and covered with matter. All the adjacent parts were sound.

When a bronchocele is the cause, there is no palliating the difficulty of swallowing caused by it, further than that of which the bronchocele admits, which we have found to be inconsiderable.

Hoffman observes, that mucus not unfrequently concretes, during the night, in the fauces and gullet, and is afterwards with difficulty brought up. This proceeds not from the aspera arteria, or the pharynx, or the pituitary tunic of the nose, but from the glands of the œsophagus itself, from a torpor in their vessels, from too violent and too frequent previous stimulus on the stomach. He recommends diluents and mineral waters as the principal remedies, and relates a case in which a cure was effected by abstinence from a more generous diet, and the use of a soft and slender one; drinking the Egra waters, omitting suppers, and taking a dose of a nitrous powder in a draught of cold water at bedtime.

Indurations happening in any part of the œsophagus are causes of a difficulty of swallowing, an instance of which is already noticed. These tumours rarely admit of relief. In the History of the Royal Medical Society in Paris, for the year 1776, we are told that a young lady, aged sixteen years, after being troubled for about three months with a spasmodic cough, began to have a difficulty of swallowing, which increased so fast, that after a very short time she was incapable of taking any nourishment by the mouth: so that, for the space of three months, life was supported solely by clysters. Mercurial and other frictions were employed without effect. At length M. Macquart, reflecting on the case, and conjecturing that an encysted tumour existed in the œsophagus, and that it might probably be now in a state of suppuration, he resolved to administer some substance, which, by its weight, might occasion a rupture of the sac. For this purpose he prescribed an ounce of crude mercury, mixed with the yolk of eggs, to be swallowed every three hours. This remedy was taken, and the patient, soon after she had swallowed the second dose, brought up a considerable quantity of pus. From this moment she was able to swallow broth, and by proper care recovered. When scrofulous indurations happen about the œsophagus, the ung. hydrargyri, rubbed on the neck over the induration, or small doses of calomel, have often been of singular efficacy, especially if used early after the attack of the disorder. If the case is of more considerable duration, the mercurials should be given so as to excite and support a moderate pytalism for some time.

In the London Medical Observations and Inquiries, vol. iii. p. 85, is the history, &c. of a case, in which deglutition was obstructed, from a preternatural dilatation of a bag formed in the pharynx. This instance was produced by a cherry stone lodging in the throat, which was returned three days afterwards by a fit of coughing; the part where it had lodged gradually expanded, and retained a part of the food taken at each meal. At last all the aliment returned, without causing either pain or sickness. It is proposed in a similar case to pass a tube into the œsophagus, and through it, to inject a due quantity of broth; by which life may be continued many years, and the enlargement of the sac will be thus prevented.

DEGLUTITION PREVENTED BY SPASMS. See ŒSOPHAGUS.

When debility occasions difficult deglutition, bark, port wine, and a generous diet, assisted by drawing electrical sparks from the neck, will often succeed. A blister on the back part of the neck has sometimes been effectual; and even the irritation of introducing the probang we have thought useful, in exciting the action of the languid fibres.

Foreign bodies sticking in the passage to the stomach are no unfrequent cause of this disorder. Many are the contrivances for removing them; but it would often be better to leave the case to nature, than to irritate so tender a part, which must be the effect of such attempts. If the substance can be reached with the fingers, or with the forceps, the extraction is easy. When pins, fish bones, or similar bodies, stick across the gullet, some recommend a wire with its end turned up like a hook to be passed below these bodies, and then turned

so as to bring them up. Pins, and other sharp bodies, when they have stuck in the throat, have been returned by swallowing a piece of tough meat tied to a strong thread, and then pulled up again. If the detained body may more safely be pushed down, the probang, a flexible piece of whalebone, with a piece of sponge secured to its end, is a safe instrument. It hath frequently happened, that though indigestible bodies have been swallowed, no inconvenience hath arisen from them. If the bodies cannot be easily moved up or down, endeavours should not be continued long, lest inflammation come on. If the patient can swallow some softening liquid, barley water, or milk and water, may be taken; and if he cannot swallow, an assistant may inject some similar fluid into the gullet, which will not only abate inflammation, but will sometimes loosen the impacted body. When endeavours fail, the patient must be treated as if labouring under an inflammatory disease; and the same treatment will be required if an inflammation take place in the part, after the obstructing body is removed. A proper degree of agitation hath sometimes succeeded in removing the obstructing body, better than instruments. Thus a blow on the back hath often forced up a substance that stuck in the gullet or windpipe. Pins, which have stuck in the gullet, have been discharged by riding on a horse or in a carriage. If the gullet is strongly contracted, so that the patient cannot swallow, he may be supported by means of clysters until relief is obtained. If there is danger of suffocation, the operation of bronchotomy will be necessary; but sometimes the obstructing cause is seated below the part where the trachea can be opened. If an indigestible substance is forced into the stomach, the patient should live on a mild smooth diet, consisting chiefly of farinaceous matters, as puddings, soups, &c. carefully avoiding whatever will irritate or heat.

In the London Medical Observations and Inquiries, vol. iii. p. 7, is an account of a small fibre of a feather being swallowed, and extracted by means of a probang, with a thread or two passing from one end to the other, and fastened to the sponges which were connected with each end of this instrument.

In the Medical Museum, vol. ii. are several instances related of different bodies sticking in the œsophagus, and the methods by which patients were relieved. In the same volume it is observed, that many bodies are not much to be dreaded when they arrive at the stomach, though they have passed the œsophagus with difficulty. Pieces of money of various sizes have passed by the anus in a few days: pieces of lead, as bullets, have at last been discharged, though sometimes they have been detained for years.

In the London Medical Transactions, vol. iii. p. 30, is an account of a crown-piece which a man swallowed. An emetic was given, but without discharging the piece, which, after twenty months, was brought up by a spontaneous vomiting.

VOL. I.

DE'GMOS, (from *δανωω*, to bite). A biting pain in the orifice of the stomach, such as is perceived in the heartburn.

DEHE'NE. See SANGUIS.

DEHISCENS, (from *dehisco*, to gape). OPENING, or GAPI'NG WIDE. It is applied to the pod of vegetables.

DEJE'CTIO, (from *dejicio*, to cast out). A discharge of the excrements by stool. The prognostics from this evacuation may be seen in Prosper Alpinus's Presages.

DEJECTO'RIA, (from the same). See PURGANTIA.

DEINO'SIS, (from *δεινωω*, to exaggerate). EXAGGERATION. Hippocrates uses this word with respect to the supercilia when enlarged.

DELACRYMATI'VA, (from *de* and *lachryma*, a tear). DELACRYMATIVES. Medicines which dry the eyes by first discharging tears, such as onions.

DELA'PSIO, (from *delabor*, to slip down). See PROLAPSUS.

DELA'TIO, (from *delatus*, shown). See INDICATIO.

DELETE'RIOUS, (from *δηλεω*, to injure). Pernicious, or extremely noxious: an epithet of poisons.

DELIGA'TIO, (from *de* and *ligo*, to tie). A BANDAGE.

The design of bandages is chiefly to secure the dressings, or to confine the motion of parts which might be painful or injurious. In ulcers, they support the dressings, defend the newly formed skin from any force which might separate it, and bring the edges both of these and of wounds nearer; so that there will be less for nature to supply. That they support and preserve the ends of fractured limbs in a proper position, is too obvious to be particularly pointed out. In some instances they are necessary to keep parts asunder; and are very frequently useful in preventing a too luxuriant growth of new parts, accumulations of purulent matter in sinuses, of watery fluids in the extremities, as well as in confining prolapsed organs.

Bandages are made of linen, cotton, or flannel. They should be, if possible, without a seam, and linen is wove for this purpose; but the selvaige is always harsh, and as the edges are necessarily covered by the next round, they are sometimes inconvenient. We prefer, therefore, old linen; and more readily submit to the inconveniences of the edges unravelling, than to the irregularity which any stitching would produce. The length often renders seams necessary. The pieces must, therefore, be united by back stitching, and beat smooth.

Linen is generally preferred for bandages; and it should be such as has been long worn, as its harshness is thus diminished or destroyed. We have lately employed cotton (calico), and have perceived many advantages from its softness and elasticity. Where some motion of the part is necessary, flannel is preferable, from its greater elasticity; and it is used in ulcers of the legs, wounds of the thorax, and in the operation of the paracentesis: all its advantages are, however, to be found in calico.

The application of bandages can scarcely be taught by words; actual observation, and, indeed, experience, are required. The young surgeon should therefore be exercised in applying them to a proper figure, for it is a

part of his profession which every nurse can judge of. Should he perform it without effect or dexterity, he will have little credit for talents in any other branch. It is, however, often of importance, that the pressure should bear equally on every part; that in other cases it should gradually increase or lessen; and occasionally the force of the bandage is limited, while the parts above and below are useful only as they support the principal. With all these views, the surgeon should accustom himself to apply them; and he will find considerable assistance in the works of the French surgeons, who roll over an affected part many yards of bandage with the utmost dexterity and neatness. See Heister's Surgery, vol. ii. tables 37 and 38.

Bandages are either simple or compound; but they are sometimes divided into general and particular: and the latter are often denominated from the part to which they are applied.

A simple bandage is a long piece of linen or cotton of an indefinite length, and from three to six inches in breadth. When applied, it is usually rolled up; and the rolled part is styled its *head*. When rolled from each end, it is styled a *double-headed bandage*. The part applied to the limb should be the opposite to that on which it is rolled, so that it may *unroll* from above, and not embarrass the operator. In the circular turns, it should be unrolled towards the surgeon, and great care should be taken that the edges are kept smooth. This will seldom be effected, unless at least one third, often one half, of the bandage is covered by the succeeding turn. The first turns should be wholly circular, for security.

The bandage is frequently returned to secure the edges, and prevent its slipping. This is effected by folding it, at a right angle, when it can be easily rolled the opposite way without any gaping edge. The chief of the simple bandages are, the *circular*, the *spiral*, the *uniting*, the *retaining*, the *expellent*, and the *creeping* bandages.

The *circular* bandage is the simplest form; the rolls cover each other, and it is seldom long, as two or three rolls are sufficient. The *spiral* bandage is that already described; and modern practice has extended its utility, by applying it in many obstinate diseases, where it is the only remedy. In the upper extremity, the fingers are first swathed with smaller fillets, and these secured on the back of the hand by the larger bandage; it is then carried up the arm to the elbow, where the bandage is crossed in the form of a figure of 8, as after bleeding, and from thence up the humerus, where it must be returned. The toes need not be swathed; but the heel must be confined by a piece of linen drawn tight, and secured with the roller, and the cavities on each side of the tendo-achillis filled with lint. The bandage is then carried to the calf of the leg, to the knee and thigh reversed, where the increasing bulk prevents it from lying smooth. In these cases the bandage must not be too tight, especially if it is to be wetted; for it is contracted by moisture. If the proper degree of tightness cannot be ascertained, it may be applied wet.

The *uniting bandage*, or *spica descendens*, used in rectilinear wounds, made with a double-headed roller, with a longitudinal slit in the middle, of three or four inches long. After dressing the wound, compresses

should be applied on each side of it, so as to press from the bottom to the lips of the wound, before the roller is applied; which roller having one head passed through the slit, an opportunity will be given of drawing the lips of the wound together. The whole must be managed so that the bandage may act equally. Where wounds are stitched, this bandage supports the stitches, and prevents their tearing. When the wound is deep, a long compress is to be applied on each side, to secure a pressure at the bottom. When the wound is very long, two or three bandages should be employed, and great care must be taken that the pressure is perfectly equable.

Henkel and Richter recommend for this purpose a compound bandage, consisting of four straps of linen of the usual breadth, and a length suitable to the wound. These are united by six narrow straps crossing each other like the fingers of the hand when folded. When applied, the middle of the bandage, or the narrow straps, cover the wound, and two of the heads on each side of it cover each other. The two lowest are then placed circularly round the limb. The two heads are drawn tight with both hands, and fastened. As the narrow straps lie over the wound, we have thus a constant view of it.

The *retentive* bandage is usually the single-headed roller. It should be applied first on one side, opposite to the wound, and brought round, so as to bring the lips of the wound closer. The contrary manner separates the lips.

The *expellent* bandage is designed, by an equable pressure, to keep the fluids within so near to the orifice of the wound that sinuses may be prevented. In general, a compress of unequal thickness is necessary; and the thinner part of the compress is placed next, and immediately contiguous, to the orifice: the thicker below. Before it is fixed, the pus must be completely pressed out, and the rolling begun with two or three circular turns on the lower part of the compress. The bandage must then be carried spirally, but somewhat slacker, upwards, and again return to its commencement. It becomes an uniting bandage when a piece of flesh is lacerated, and we wish to heal it by the first intention.

The *creeping* is a simple bandage, where the succeeding turn only covers the edge of the preceding. It is employed where the object is merely to secure the dressings, and not to make any considerable or equable pressure.

The *compound* bandages are the *eighteen-tailed*, or rather the *many-headed*, bandage, and the *T* bandage. The first consists of three pieces of linen, about a foot in length and in width. These are sewed together in the middle, and each end divided into three equal parts; the division continued to about two inches and a half from the centre. These are arranged so as to press equally on the limb, which it will do, if the head which overlaps is received in a slit of the corresponding piece. This bandage has been varied by Dessault and others, in a manner which we find almost incapable of being conveyed by words.

The *T* bandage is chiefly used in injuries of the abdomen and back; but particularly of the genital organs, and the neighbouring parts. It is of the shape of the letter. The transverse part passes round the waist, and the other part between the legs. If the latter is

divided, it may press on either groin, when brought up to unite with the bandage which surrounds the waist.

We shall add a short description of some other bandages, neither simple nor compound, before we proceed to the particular ones.

The *triangular* bandage is generally a handkerchief doubled into that form. In common cases it is used on the head, also as a support to the testicles when swelled, called by the French *couvre-chef en triangle*.

The *nodose* bandage, called *scapha*. It is a double-headed roller, made of a fillet four yards long, and about an inch and a half broad; it must be reversed two or three times, so as to form a knot upon the part which is to be compressed. It is employed when an hæmorrhage from a wound is to be stopped, or for securing the compress after bleeding any part of the head.

The *quadrangular* bandage is about three feet square, or a little longer than broad. The French call it *le grand couvre-chef*.

The *reflex* bandage. See CAPELINA.

The particular bandages we shall consider under the article FASCIA.

For the practice of the ancients in this part of surgery, see Vidus Vidius. For more modern directions, Heister's Surgery; M. M. Sue, and Thilloye; Pott's Works; Bell's Surgery, vol. vi. p. 469; Lonibard and Bernstein.

The *scapularia*, *scapulary*, and *najkin*, is a piece of cloth four or six fingers broad, with a slit in the middle to pass the head through, and long enough to reach from the bottom of the sternum over the shoulders, and down the back, as low as the sternum is before. For the *spica inguinalis*, *inguinalis duplex*, and *simplex*, see SPICA. The *STELLA*, *MONO'culus*, *DISERIMEN*, *HABE'NA*, *HEMICERAU'NIOS*, *AURI'GA*, *CHIASTOS*, *CHIA'STE*, may be found under their respective heads. For *circulus*, and *plinthus laqueus*, see CIRCUS QUADRUPLIX.

*DELIQUA'TIO*, (from *deliquo*, to melt). See SOLUTIO.

*DELIQUESCENTIA* and *DELIQUIUM*, in chemistry, imply a spontaneous solution which some salts experience by exposure to the air only. This effect is owing to their very powerful affinity for moisture, which draws to them the portion of vapour dissolved in the atmosphere.

*DELI'QUIUM ANIMI*, (from *delinquo*, to swoon). See LIPOTHYMIA.

*DELI'RIUM*, (from *deliro*, to rave, or talk idly). It is termed also *alienatio mentis*, *paranoiæ* *paraphrenesis*, *dementia*, sometimes *emotio*. When the ideas excited in the mind do not correspond to the external objects, but are produced by a diseased state of the common sensory, the patient is said to be delirious. In madness, reason is destroyed; in foolishness (*morosis*), is defective; and in the delirium, vitiated. Delirium is commonly a symptom of fever, occasionally the effect of narcotic poisons. In general, the objects do not produce the accustomed impression, or are followed by the usual associations. It usually arises from an unequal state of activity in different parts of the brain, and differs from madness only in duration, or the presence of a disease of which it is a symptom.

Galen observes, that delirium is caused by the heat and acrimony of the fluid, but principally by yellow bile. (See his book *De Sympt. Caus. lib. ii.*) Many other writers think that the bile is the cause. No great

danger is to be apprehended from delirium, whilst the pulse, the appetite, and respiration, are favourable.

*DELI'RIUM MANIA'EUM*. See MANIA.

*DELI'RIUM MELANCHO'LICUM*. See MELANCHOLIA.

*DELI'RIUM FEBRILE*. See FEBRIS.

*DELOCA'TIO*, (*de*, from, and *locus*, a place). See LUXATIO.

*DELO'TICOS*, (from *δελον*, manifestum). INDICATIVE: used in this sense by Hippocrates, in his Aphorisms; in general, diagnostic signs. See DIAGNOSIS.

*DELPHI'NIUM STAPHIS A'GRIA*, (from the flower resembling the dolphin's head). See STAPHIS AGRIA.

*DE'LPHYS*, (from *δελφος*, the womb). See UTERUS.

*DE'LTÀ*. The name of the letter Δ in the Greek; also the external pudendum muliebre, so called from the triangular shape of the hair.

*DELTOI'DES MUSCULI*. The DELTOID MUSCLES, (from *delta*, and *ειδος*, likeness; *musculi triangulares*, and *humerales*). They rise from the anterior edges of the extremities of the clavicles, which join the acromions; from the acromions, and from the spines of the scapulæ; and are inserted into the middle of each humerus respectively. They move the arm forward, upward, and backward.

*DEME'NTIA*, (from *de* and *mens*, without mind). See VESANIA, and DELIRIUM.

*DEME'RSUS*, (from *dermergo*, to sink down). In botany it is applied to aquatic plants, and means sunk below the surface of the water.

*DEME'TRIAS*. See CEREALIA.

*DEMO'CRATIS THERIA'CA*. A theriaca described by Ætius; called from its inventor.

*DEMOTI'VUS LA'PSUS*, (from *demoveo*, to send back). SUDDEN DEATH.

*DEMULCE'NTIA MEDICAME'NTA*, (from *demulceo*, to soften). DEMULCENT MEDICINES sheath the acrimony of the humours, and render them mild. Dr. Cullen says, they are such as are suited to correct acrids, or to obviate the irritations arising from them. Emollients are occasionally demulcents; for they often sheath acrid humours, and soften rigid fibres. See EMOLLIENTIA.

Demulcents are of two kinds, viz. general, or specific, obtunding only a particular acrimony.

The general sort are, 1st, All oils obtained by the expression of fruits, or formed by boiling vegetable substances containing them; the oil distilled from wax, and all animal fats. 2dly, All insipid inodorous plants that yield no oil, but are merely mucilaginous. 3dly, The viscid insipid gums. 4thly, All the animal gelatines and albumens. Watery fluids, usually styled *demulcents*, are rather to be considered as DILUENTS; q. v. The specific demulcents are those which unite by chemical affinity with the acrid: these are chiefly alkalis and acids, when the acrimony is of the opposite kind. Bitters are supposed to be demulcents when the acrimony is bilious: vegetable acids are more certainly such in the same case. The other acrimonies described by authors are numerous, but generally imaginary, except probably the saline, for which diluents are the remedies.

*DENA'RIUS*, (from *denus*, ten; because the Roman denarium marked with the letter X meant ten asses, a coin so called).

**DENDR.** An abbreviation of dendrographia, or dendrologia, a description of, or discourse on, trees, from *δενδρον*, arbor, a tree, and *γραφη*, scriptura, seu *λογος*, sermo.

**DENDROI'DES**, (from *δενδρον*, a tree, and *ειδος*, likeness). Plants that resemble trees: they are also called *arborescent*.

**DENDROLI'BANUS**, (from *δενδρον*, tree, and *ολιβανον*, frankincense.). See **ROSMARINUS**.

**DENDROMA'LACHE**, (from *δενδρον*, and *μαλαχη*, the mallow). See **MALVA ROSEA**.

**DENODA'TIO**, (from *denodo*, to loosen). See **DIS-SOLUTIO**.

**DENS**, (quasi *edens*, from *edo*, to eat, or from *οδους* edon'os). A **TOOTH**. The teeth are usually sixteen in each jaw; they are divided into the body above the gum, and the root, or fang, which is within the socket of the jaw; the neck is the line of division between the root and the body. They are composed of a bony substance and an enamel.

Little attention was paid to the teeth before the period of Eustachius, whose work appeared in 1563. He was followed by a French surgeon, Urban Hemard, about twenty years afterwards; but though the teeth and their diseases were more frequently mentioned in anatomical and chirurgical works, we find no express treatise on the subject till the year 1740, the date of Fouchard's work. This author was followed in 1771 by Mr. J. Hunter; by Dr. Blake in 1798; and Mr. Fox in 1803.

The enamel covers only the body of the tooth, that part which is not covered by the gums, so far as to its neck: it is not vascular, nor capable of being injected: for if animals are fed with madder, the body of the tooth will be coloured, but the enamel will remain unaltered; or, if the enamel be steeped in a weak acid, it will become a powder; but if bone is thus steeped, a soft elastic part remains.

Chemically examined, the enamel consists, like bone, of phosphat of lime, and gelatine, viz. of 29.67 parts of phosphoric acid; 43.3 of lime; and 27.10 of gelatine and water. It is generally agreed that the enamel is never reproduced. It certainly is not when broken to the subjacent bone; but its surface seems to be occasionally supplied, though its hardness prevents injury from attrition.

Each root is hollow, for the admission of vessels and nerves to pass into the substance of the teeth; but these cavities grow less in advanced age.

Ossification begins in the body of a tooth, and is continued to the root; and there are as many points of ossification as there are tubercles in the tooth. Mr. John Hunter suspects that the teeth, when full grown, are not simply bone. He observes, that bones are tinged with the colouring matter of madder when they are complete and perfectly grown, if the animal is fed for a time with this root; and teeth, whilst growing, receive this tinge, but not when they are perfected. In all other bones this red colour is, in time, carried off by absorption, and they return to their original colour; but a growing tooth, if coloured, never loses it. This does not show the want of an absorbent system, for teeth, when their nerves are destroyed, seem to be slowly absorbed; and they certainly continue, while alive, to be vascular. The whole anomaly seems to arise from the

minuteness of their vessels. The rickets do not affect the teeth; for we never find them grow soft like the bones, but they remain perfectly hard: lastly, in old age, the other bones become brittle and waste; but the teeth, except when carious, continue in their former state.

The teeth are divided into three classes, viz. the *incisores*, *canini*, and *molars*. The incisores, called also *dentes lactei*, and *dentes risorii*, are the four anterior teeth in each jaw; they appear the first. The canini, or *dentes oculares*, are one on each side of the incisores, in each jaw. The molares are five on each side of both jaws. Sometimes before twenty years of age, often about five or six and twenty, the last of the grinders appear, and are called *dentes sapientiæ* and *dentes genuini*. Mr. John Hunter divides and names them as follows; viz. from the symphysis of the jaw on each side, are two *Incisores*, q. v.; one *cuspidatus*, (see **CANINI DENTES**); two *bicuspidæ*; and three *molars*, the last of which is the *sapientiæ dens*. See **MORALES**.

The incisores, canini, and the two first of the grinders, are formed at the birth, and are those teeth which are shed. They usually appear about the seventh month, and are shed about the seventh year. The secondary teeth are formed in sockets of their own, which are situated below the other socket. The three *dentes molares* on each side do not come through the gums until the first set of teeth is shed; then they come through with the second set, and are never shed. Some people never have the last molares. At about three years of age a child hath the whole of its first set of teeth, which are twenty.

There are generally as many protuberances on the body of the teeth as there are roots: but the latter sometimes grow together; at other times they are divaricated, especially in the upper jaw, where, not having a sufficient depth, because of the maxillary sinus, they spread and are extracted with greater difficulty than those on the lower jaw.

The fifth pair of nerves supply the teeth with branches, which, with the blood vessels, are surrounded by a membrane, and, running under the teeth, enter into the cavities through a hole in the roots. From an attention to the fifth pair of nerves, and the parts to which they are distributed, many of the phenomena attendant on disorders of the teeth may be explained. It is in general supposed that the teeth, when a child is born, are lodged in sockets in the jaw-bones, and are covered with, and enveloped by, a thin, very irritable, and sensible membrane, the periosteum of the teeth; so that when the teeth begin to grow, they must necessarily distend, and force their way through this membrane, which, from its sensibility, gives great pain, and occasions fevers, startings, and all the symptoms of teething. As soon as this membrane is completely divided in that part by the tooth, the child is relieved for the present from the fever and other complaints; which are subject to return upon the successive rising of the other teeth.

This general account must be admitted with many restrictions, derived from more minute inquiries. The teeth are formed in the fœtus, and even the rudiments of the second set are very early conspicuous. They ossify in distinct points; and, at the period of birth, these ossified points are nearly contiguous. They are covered with a membrane which is divisible into two

layers; most dense and thick near the edge of the jaw, and softer as well as more gelatinous below. The external layer is spongy and vascular; the internal more tender and delicate, without vessels: though Mr. Hunter, perhaps from accident, has inverted this order. The membrane is fastened to the neck of the tooth, which, pressing against it, deprives it of life, and thus occasions its absorption, as well as of the gum above. Laceration seldom takes place, though in some instances it seems to do so, as the ragged edges have been observed. In general, the diseases attributed to dentition do not arise from the distention of this membrane, but to the state of the stomach, and are often relieved by a slight opiate, with the volatile alkali. It has been a too common practice to divide the gum; but this is an unnecessary severity, and often useless. It is only when the tooth distends it considerably, with violent inflammation, that such an operation is admissible.

Disorders in the teeth, in more advanced age, depend chiefly on a caries, and an inflammation in the membrane which covers their root. When a tooth is carious, it often occasions a fetid breath; and the air passing into, or any warm or cold substance touching it, excites pain. Relief is often obtained by filling the carious part with opium for occasional relief; but with gold or silver laminæ for more permanent ease. When the membrane which spreads itself about the roots of the teeth is considerably inflamed, bleeding or purging, according to the state of the constitution, will be needful; warm barley water may also be held in the mouth, and the methods useful in other inflammatory disorders may be employed. Blisters may be applied behind the ears, or on the back; and horse radish or pellitory root may be held between the gums and cheeks, to excite a discharge of saliva. Besides these general causes, scorbutic and venereal complaints will affect the teeth; in which cases, the method of cure will consist in general remedies adapted to them. See DENTIFRICIUM.

On the teeth, and their disorders, see Mr. John Hunter's Natural History of the Human Teeth; Eustachius de Dentibus; Hoffman de Dentibus, eorum Morb. et Cura; Hurlock on Breeding of Teeth; Moss on the Management of Children; Bell's Surgery, vol. iv. p. 191; White's Surgery, p. 280; Blake and Fox on the Teeth.

DENS CABALLI'NUS. See HYOSCIAMUS.

DENS CA'NIS. DOG'S TOOTH. *Erythronium*, *dens canis* Lin. Sp. Pl. 437. The flower is shaped like that of a lily; the root is long, fleshy, and formed somewhat like the tooth of a dog; the leaves resemble those of the cyclamen. The dried roots are commended as anthelmintic; but are not used with us. Dog tooth spar in mineralogy is one of the original forms of crystals.

DENS LE'ONIS, also called *taraxacum*, *urinaria*, *hieracium Alpinum*, *hedypnois*. DANDELION. It is the *leontodon taraxacum* Lin. Sp. Pl. 1122. It is a low plant, with long, narrow, deeply indented leaves, lying on the ground, among which arises a single, naked, hollow pedicle, bearing a large, yellow, flosculous flower, followed by small seeds, covered with a tuft of long down: the root is oblong, slender, yellowish, or brownish, on the outside, and white within. It is perennial, common in uncultivated places, and flowers from April to the end of summer.

The roots, stalks, and leaves, abound with a milky, bitterish juice, but of no particular flavour. They were supposed to be mildly detergent and aperient; but owe their credit chiefly to their milky juice, which was supposed to be saponaceous. Boerhaave highly commends them as a resolvent; but the more immediate and sensible operation of this plant is to loosen the belly, and promote urine; which it does with little stimulus, though in a slight degree; and has been considered as highly efficacious in removing biliary obstructions. Dr. Pemberton, in a late work, speaks of it with commendation in these complaints. Murray observes, that this plant resolves viscid humours, opens obstructed vessels, and is a remedy for various eruptive complaints; and Bergius considers it as an effective, hepatic deobstruent, recommending it in hypochondriasis and jaundice. He recommends it boiled in whey, or formed into broths and apozems. It has also been supposed useful in dropsies, pulmonic tubercles, and some cutaneous disorders; given in decoctions of the plant and root; or the expressed juice is sometimes administered, from one ounce to four, three or four times a day. The plant should always be used fresh; for even extracts of it, as well as the roots and leaves, lose their power by keeping. It may also be taken as part of diet, and eaten fresh. The young leaves blanched resemble in taste the endive, and make a good addition to salads in the spring. The roots are roasted, and used at Göttingen, by the poorer people, for coffee, from which a decoction of them properly prepared can hardly be distinguished.

See Raii Hist. Lewis's Mat. Med. It is also a name of the auricula muris, and some other plants.

DE'NSITAS, (from *densus*, *thick*). DENSITY. Dense bodies contain a considerable quantity of matter within a proportionally small bulk. But in medical writings, denseness sometimes means frequency, and is applied to the pulse, and to respiration.

DENTA'GRA, (from *dens*, a tooth, and *αγρα*, a seizure). It is used both to signify the gout in the teeth (see ARTHRITIS), and an instrument for drawing them, called also *dentarhaga*, *dentiducum*, *odontagogos*.

DENTA'LE VIRIDE STRIATUM. See ENTALIMUM.

DENTA'LIS LA'PIS, (from *dens*,) the tartareous matter formed on the teeth, resembling in hardness a stone.

DENTA'LIIUM, (from the same). Also called *dentale*, *autalis*, *tubulus dentalis*, and TOOTH SHELL. It is the shell of a small sea fish, oblong, slender, and of a whitish, greenish, or reddish colour; about two inches long, striated, and marked with two or three bands. As a medicine, it differs little from the oyster shell.

DENTA'RIA, (from the same). *Dentaria pentaphyllos* Lin. Sp. Pl. 912. *Coralloides*, *septifolia*, SEPT-FOIL TOOTHWORT, and CORALWORT. This plant hath a long pod, full of round seeds; when this is ripe, its valves are twisted into a spiral form, and discharge the seeds with violence: the root is squamous, fleshy, and denticulated. It flowers in April: the root is drying and astringent.

DENTA'RIA. See PLUMBAGO.

DENTARPA'GA, (from *dens*, a tooth, and *απαζω*, to fasten upon). See DENTAGRA.

DENTA'TA, (from *dens*, a tooth). The second vertebra of the neck. It is remarkable for its process,

called *processus dentatus*, which plays in the hollow of the anterior arch of the vertebra above it, called *Atlas*. From the sides of the *processus dentatus*, the ligaments go off to attach it to the *Atlas*; and from its point a strong one is sent out to the *os occipitis*. In botany a dentated leaf, called *denticulatum*, is distinguished by spreading points or teeth, remote from each other, about the edge.

DENTA'TUS PROCE'SSUS. See *ATLAS*.

DENTELLA'RIA, (from *dentella*, a little tooth). See *PLUMBAGO*.

DENTES COLUMELLARES, (from *dens*, and *columella*.) A LITTLE COLUMN. *Dentes canini* of Varro and Pliny.

DENTES LACTE'I. See *INCISORES*.

DENTES OCCULA'RES. EYE TEETH. See *DENS*. They are thus named, because their nerves are supposed to be connected with those of the eye, and that any injury they receive may equally injure that organ.

DENTES RISORII. See *INCISORES*.

DENTICULA'TA, (from *denticula*, a little tooth). Indented, or cut round in small notches. See *MOCHATELLINA FOLII FUMARIÆ BULBOSÆ*.

DENTICULA'TUM, (from the same). See *DENTATA*.

DENTIDUCUM, (from *dens*, and *duco*, to draw). See *DENTAGRA*.

DENTIFRI'CIUM, (from *dentes fricare*, to rub the teeth). DENTIFRICE; called also *odontotrimma*. Medicines for cleaning the teeth. Many preparations are employed for this purpose, chiefly consisting of scuttlefish bone, bole, bark, myrrh, salt, and soot. Each operator has his receipt, which he highly commends and conceals. Any very fine powder is apparently of equal service, but mastich and myrrh are the general bases: most commonly the former. The powder is flavoured with orris root, with ambergris, &c. and coloured with dragon's blood, bole armoniac, or red sanders, professedly to strengthen the gums, but really to conceal the bleeding from the gums. It was formerly the custom to add common salt or crude sal ammoniac to dentifrices; for what purpose we know not; but both are now disused: and one of the most boasted tooth powders that we have seen, is only magnesia coloured with rose pink. The carbonated dentifrice is merely powdered charcoal, and it has been employed chiefly from its power of destroying the colours of different fluids, discovered by Lowitz. (See *CHARCOAL*.) Soot is used from the whiteness observed on chimney sweepers' teeth; but it possesses no very peculiar merit. A sufficiently pleasant and efficacious tooth powder is made with two parts of finely powdered mastich, two parts of myrrh, and one part of cassia. It cleans the teeth, preserves them from decaying, and renders the gums peculiarly firm and hard. In fact, however, almost every powder seems equally efficacious, and, if it be impalpable without acidity, equally innocent.

The calculus concretion which forms on the teeth is of singular hardness, and with great difficulty removed; nor has modern chemistry yet discovered a menstruum which will dissolve it without injuring the enamel. Acids soften this firm covering, and render it transparent. Dentists universally reprobate their use, and we cannot, therefore, encourage it. We suspect, however, that their occasional application will not be injurious: we are, at least, certain, that the injury acids

may do is recoverable. The brushes should be hard and strong; the hairs set at some distance, that they may clean the interstices of the teeth, where the tartar lodges; and the brush should be used more in the longitudinal direction, with respect to the teeth, than across them. If the powders are perfectly fine, no injury can arise from the brush. The preservative tinctures are of little use. Their basis, like the powders, is mastich, and their appellations fanciful.

DENTILLA'RIA, (from *denticula*, a little tooth; so called because its root is denticulated). See *PLUMBAGO*.

DENTISCA'LPIUM, (from *dens*, a tooth, and *scalpo*, to scrape). Also called *odontoglyphon*. An instrument for scraping off the crust which is formed on foul teeth. In Oribasius, it is an instrument for separating the gums from the teeth.

DENTITIO, (from *dentio*, to breed teeth). Also called *odontiasis*, *odontophya*. DENTITION, or breeding of teeth. Sauvages, in his system of Nosology, makes this a species of odontalgia. Cullen makes dentitio synonymous with odontismus; but does not admit it as a disease. Hippocrates uses the word principally with respect to the gums, when the teeth are forcing a passage through them; and modern writers follow his example.

Children often suffer much uneasiness from the cutting of their teeth: though teething is not a disease, yet from accident and temperament it sometimes produces the most fatal disorders. The fever and inflammation excited in a full habit may terminate in peripneumony or suffocation; and when the child is fat and plethoric, the most cooling diet and the most active laxatives must be employed.

A troublesome cough is often attendant on teething; in which case a small blister applied to the nape of the neck is of considerable service. A fresh one may be applied when the first begins no longer to produce any discharge.

Dr. Withers observes, in his Treatise on the Asthma, p. 301, 302, that, "If a child has a disease in his breast, the cutting of a tooth, as it often excites pain, fever, and general irritability, will be found commonly to increase it. But this affords no proof why a cough and shortness of breath, with a pulmonary obstruction in the lungs, should be thought a necessary attendant on teething. According to the best of my observations, it is an indisputable fact, that healthful children cut their teeth without a cough; and when in others a cough attends teething, it is, in general, an accidental circumstance, proceeding from a local complaint in the breast, and is not merely symptomatic of the cutting of a tooth. The violence of the cough, the rising of the phlegm from the lungs, inflammations, pulmonary obstructions, and ulcerations, which have followed, and been proved by dissection, have fully convinced me of the truth of the above assertion. I should not have dwelt at all on this fact, if I had not observed that the notion which I am endeavouring to refute is pernicious to society, and productive of fatal consequences. For when we say that a cough, with shortness of breath, is a common symptom of teething, we unite the two complaints together under one idea; and as we consider teething as natural and necessary, the other, being united with it, and regarded only as an effect, falls in under the same

general idea, and consequently is too often supposed to require no particular treatment; by which means it is neglected, and in many instances proves fatal."

When children are vigorous, they cut their teeth earlier; weakly children, particularly those that are disposed to the rickets, are later before their teeth appear.

A discharge of saliva, or a diarrhœa, are favourable symptoms during the time of cutting the teeth. Children attended with these symptoms are rarely affected with convulsions, or any other violent disorder.

Hoffman observes, that the teeth appear sometimes in the seventh month, at others in the ninth, or even the twelfth. In some, this process gives but little uneasiness; in others, it is accompanied with very troublesome symptoms. In difficult dentition the child is preternaturally hot, cries immoderately, starts in his sleep, often applies his hand to his mouth, sucks with eagerness, and even bites the nipple. The gums swell, and look whitish or reddish; the saliva is copiously discharged, and often hangs viscid from the mouth; the belly either costive or too loose. Sometimes acute fevers, convulsive and epileptic paroxysms, distortions of the jaws, and other violent symptoms are joined, different in different subjects, according to the difficulty of the eruption of the teeth, or the sensibility of the child. Amongst the prognostics, he says, that those who are plethoric, sleepy, costive, those affected in dentition with a cough, who are of great sensibility, or an hereditary passionate disposition, have the most to fear. Hippocrates observes, that those who are attacked by the acute fever escape convulsions, and that the teething is easiest in winter. The principal indications of cure are, to abate the pain and inflammation, and to soften and relax the gums. If the body be not naturally lax, it should be kept so. A spontaneous looseness is salutary, and should not be checked; for convulsions and other threatening symptoms will then probably follow.

Breeding the teeth commonly begins about the third or fourth month: it may be known by a copious discharge of saliva taking place; its being pleased with having its gums rubbed with a finger, or other harder substance; its becoming more fretful and uneasy, starting in its sleep, or suddenly awaking. If now there are also great heat, thirst, fever, a dulness and drowsiness, particular attention should be paid to keep the bowels lax, if they are not already so; if a looseness at this time attends, though it is somewhat severe, it should not be checked. The griping, which occasionally accompanies this looseness, is generally abated by the use of a little magnesia, or prepared chalk. When the drowsiness, starting, and feverishness come on, bleeding with leeches will be singularly useful. Two leeches may be applied to the neck every or every other day, until these symptoms abate. During the thirst, if children crave sweetened drinks, liquorice may be boiled in the water which is given, as it does not increase this troublesome symptom. After the bleeding, blisters behind the ears, or on the back, are not to be omitted. The antimonial emetics should be repeated occasionally until the fever is removed; and, in many cases, the *sp. cornu cervi*, recommended by Sydenham, is useful. Should convulsions come on, the above treatment will be also well adapted to relieve. A discreet use of anodynes is an important addition in this instance; and, in general, after free

evacuations they may be given by the mouth, or in an enema. The second stage, or period of teething, is that of cutting the teeth. This usually begins about the seventh or ninth month: in this the symptoms or management are, in general, the same as those of the first period. A child, however, who a little before was pleased with having his gums rubbed, will now seldom suffer any thing to touch them; for when a tooth is penetrating the gum, it is exceedingly sensible of pain from the slightest touch. It may be known that a tooth is near cutting, when the gum in one particular part appears fuller and more distended than usual; the gum in that part looks red, and is inflamed at the bottom or base, but is paler or whiter at its point or edge; and when the tooth is very near, the edge of the gum seems as if it was covered with a flat white blister, appearing also thicker and broader than the edges of the gums in other places: at this, but at no other period, if any alarming symptoms come on, cutting the gum over the edge of the approaching tooth, will be a speedy and often an effectual means of relief. If cut earlier, though the symptoms abate, the tooth will not appear for some days, or perhaps weeks. Sometimes the gum heals, and the former uneasy symptoms return; and it has been necessary to repeat the operation frequently; a severity which, though the wounded gum should not unite with a hard cicatrix, is to be discouraged. It is, however, by no means certain, that the subsequent operations are not more painful, and that the appearance of the tooth is not retarded; that repeated cutting the gum renders it harder; for the contrary is said to take place; on which see J. Hunter's Practical Treatise on the Diseases of the Teeth, p. 121. Bell's Surgery, vol. iv. p. 191. White's Surgery, p. 280, &c.

DE'NTO, (from *dens*, a tooth). One whose teeth are prominent to a great degree.

DENTODU'CUM. DENTIDUCUM. See DENTAGRA.

DENU'DA'TIO, (from *denudo*, to make bare). DENUDATION. It is spoken of parts that are laid bare by the flesh being torn from them.

DENU'DA'TUS, (from the same). An order of plants in the vegetable kingdom, whose flowers are naked.

DEOBSTRUE'NTIA, (*de*, priv. and *obstruo*, to obstruct). DEOBSTRUENTS. DEOPILATIVA.

DEOBSTRUENTS. This is a class of medicines formed without any precise or definite object. Obstruction was a cause of convenient application, from its vague indefinite meaning; and, while lentor and viscosity were the sources of diseases, deobstruents were common remedies. We declined speaking of them in the class of aperients; as for these medicines there was an apparent foundation, we mean not to say that there is not some foundation for the present group, yet it is less clear and satisfactory.

Obstruction, during the reign of the humoral pathology, was, as we have hinted, frequently introduced as a cause; but though fevers and inflammations were then ultimately resolved into obstruction, deobstruents were confined exclusively to chronic complaints: of these, infarctions of the viscera were chiefly attacked by gentle laxatives, from this effect styled aperients, of which we have already spoken.

The obstructions to be removed by this class of me-

dicines, are those of natural discharges, or infarctions of organs, whose utility is less obvious, and from which no excretory ducts proceed. The natural discharges, to restore which we employ deobstruents, are those of the menses, of the hæmorrhoidal vessels, of the nose, the lungs, and the skin. The first we must treat of under the title of EMMENAGOGUES; the second we have spoken of in the article CATHARTICS; the others will occur under the articles of ERRHINES, EXPECTORANTS, and DIAPHORETICS. Our present object is, then, those tumours out of the circulation, or in parts where the circulation is languid, and from which no excretory ducts proceed.

We have already stated, that where obstruction occurs, two modes of treatment offer themselves to our notice; the one consists in forcing on the circulation, by increasing the vis a tergo; the other in moderating too great action, in order to prevent the fluids from being further impacted, the obstruction increased, and suppuration supervening. The first can seldom be effected by violent stimulating remedies; yet we have had occasion to show, that mercury, by slowly and steadily increasing the action of the arterial system, and of course the momentum of the blood, sometimes succeeds. It certainly, at times, removes complaints of the liver; sometimes, though rarely, scirrhus tumours of the breast, and other parts where its topical application by friction can be combined with its internal stimulus. The internal use of arsenic, in cancers, must be referred to the same head; and other stimuli sometimes succeed in different complaints. The tartar emetic ointment has been useful in bronchocele, and occasionally in the white swelling of the knee. In the latter also, the arum, and the gum ammoniacum, with squills, have been successful. These, then, are deobstruents from their stimulus. When the application of sea weeds and sea salt, with their internal use, relieves cases of scrofula; and mesenteric tabes, or the burnt sponge, under the tongue, lessens the bronchocele; they appear to be useful in the same way.

The sedative or refrigerant deobstruents are medicines of the same classes, though they have not been usually arranged under this head. When we give nitre, and employ the antiphlogistic regimen in cases of tubercles in the lungs, we use them as deobstruents. A similar treatment is often, for the same purpose, adopted in incipient cancers. The general remedies of this class, however, besides opium, are, the cicuta, the lactuca virosa, the belladonna, the aconite, and the various genera of the same order. These have been used as deobstruents in other parts of Europe, it is said, with success. We have to regret that we cannot add our testimony to their efficacy.

It has not been uncommon to unite the two orders of deobstruents; and not long since fashionable to join the extract of cicuta with mercury in tubercular consumptions; arum, with the same preparation, as an application to white swellings; mercury, antimony, and opium, in internal obstructions; and mercury, with camphor, externally applied.

We have enlarged on this class more fully than, perhaps, its importance might have demanded; for, from being highly valued, it has been neglected in the later systems. It was proper, therefore, to show, that the establishment of this association was not wholly theoretical, and to point out its real foundation.

DEPART. See DISCESSUS. It is also called *quartatio*, which see.

DEPA'SCENS U'LCUS, (from *dehasco*, to eat down). See PHAGEDENA.

DEPENDENS, (from *dependo*, to hang from). DEPENDENT. In botany it means hanging down, pointing towards the ground.

DEPERDITIO, (from *deperdo*, to lose). See ABORTUS.

DEPETITGO, (from *de*, and *petigo*, a running scab). See PRURITUS.

DEPHLEGMA'TIO, (from *de*, and *phlegma*, *phlegm*). Vinous spirits are said to be dephlegmated, or rectified, when freed from the usual proportion of water.

DEPILATO'RIUM, (from *de*, and *pilus*, hair). DEPILATORY. Medicines which take off the hair, such as quick lime and orpiment. There are three kinds of depilatory medicines: 1. The *psilóthra*, or *depilatória*, by way of eminence; 2. Those which thin the hair; and, 3. Those which are corrosive, and extirpate the hair. The first and third are nearly the same, at least the hair cannot be effectually taken off unless its roots are destroyed.

DEPI'LIS, (from the same). See ALOPECIA.

DEPOT LAITE'UX. See LYMPHÆ DUCTUS.

DEPLUMA'TIO, (from *de*, and *pluma*, a feather, or hair). An affection of the eye lids, with a callous tumour, which causes their hair to fall off. *Ætius* says, it is a disorder in the eye, consisting of a *madarosis* and *sclerophthalmia*.

DEPREHE'NSIO, (from *deprehendo*, to catch unawares). See CATOLEPSIS.

DEPRE'SSIO, (from *deprimo*, to press down). A DEPRESSION. In surgery this word generally signifies a sinking of some part of the skull, which happens from an external violence, by which the bone is fractured, or pressed inwards. This injury is sometimes named *impressio*, *introcessio*.

In this case, the same symptoms may attend as are observed in an extravasation within the skull, and are caused by the same means, viz. mechanical pressure: they differ widely from those of a concussion of the brain. See CONCUSSIO, EXTRAVASATIO, CERBERI, COMPRESSIO.

Dr. Hunter seems to think, that it is almost impossible to raise a depression of this kind, because the fracture is usually more extensive in the inside than externally, and the spiculæ can never be brought exactly to fit each other. But as, according to Hildanus and Vander Weil, some skulls have been depressed without fracture, success may be expected, at least, in some cases; and where the bones are soft and yielding, they may be raised by means of a string fastened to an adhesive plaster, which may be applied to the depression, after shaving the part. But, after all, if their elevation were easily practicable, it would not be advisable, in general, to be contented with mere elevation; for all the ills attending and succeeding simple fractures, are more likely to happen from depressed pieces of bone; therefore the depressed pieces should be generally removed.

DEPRE'SSOR, also *deprimens*, (from *deprivo*, to pull, or draw down). In anatomy, a name applied to several muscles, because they depress the parts to which they are fastened.

DEPRE'SSOR ANGU'LI O'RIS. A name given by

Albinus to the *depressor labiorum communis*. It rises from the outer part of the lower edge of the lower jaw, at the side of the chin, and is continued outwardly, to the greater zygomaticus, to the nasalis of the upper lip, and thence into the outer part of the orbicularis, where it surrounds the upper lip at the corner of the mouth. It extends and joins the elevator of the corner of the mouth.

DEPRESSOR EPIGLOTTIDIS. It rises from the ligament on the thyroid cartilage on its fore part, and is inserted in the epiglottis, near its basis, on each side.

DEPRESSOR LABIORUM COMMUNIS. See DEPRESSOR ANGULI ORIS.

DEPRESSOR LABII SUPERIORIS; *triangularis, constrictor alæ nasi*. It rises from the sockets of the incisores, runs to the superior part of the upper lip, and sends some fibres to the nose.

DEPRESSOR O'CULI: *humilis rectus inferior, depressor musculus inferior*. It rises tendinous from the back part of the socket, cohering in some measure with the covering of the optic nerves, and is inserted into the fore part of the sclerotica, after running under the eye.

DEPRESSOR SUPERCILII. See CORRUGATOR COTERNI.

DEPRESSORES ALÆ NASI. The plural of *depressor*. The DEPRESSORS OF THE WINGS OF THE NOSE. They arise from the upper jaw bone outwardly, where the gums cover the sockets of the dentes incisores and canini, and are inserted into the root of the wing of the nose, advancing a little way up the side of the wing: they pull the alæ downwards.

DEPRESSORES COSTARUM. They are so similar to the levatores longiores, as to need no further description: their office is the reverse of the other.

DEPRESSORES LABII INFERIORIS. Also called *quadrati*. They arise fleshy on each side of the chin, proceed obliquely, and, crossing each other, terminate together in the whole edge of the lip, where it grows red.

DEPRESSORES MAXILLÆ INFERIORIS. See PLATYSMA MYOIDES.

DEPRESSORIUM, (from *deprimo, to depress*). An instrument used for depressing the dura mater after the operation of the trepan.

DEPRIMENS, (from *deprimo, to depress*). See DEPRESSOR, and DEPRESSOR OCULI.

DEPURATIO, (from *depuro, to purify*). DEPURATION, *clarificatio, despumatio, vel rectificatio*. It is the freeing of any fluid from all heterogeneous feculence, and rendering it more transparent. This operation is of three kinds: 1st. DECANTATION, which can only take place where there is a difference in the specific gravity of what constitutes the mixture; so that the lighter part can be poured off. When oils are to be separated from water, or indeed from other fluids, a tritorium, or separatory glass, is used. 2dly. DESPUMATION. The principle of this mode of depuration is the existence of air in the fluid, which, when rarified by heat, rises to the top, carrying with it the feculæ, which may be separated by a spoon. 3dly. CLARIFICATION, performed by adding the whites of eggs, or such fluids as will coagulate by means of heat, and entangle all the heterogeneous matter, which may be easily separated. 4thly. FILTRATION OR PERCOLATION, performed by passing, without pressure, the fluid to be purified through

strainers of linen, flannel, or paper, which, retaining the feculence, permit only the clearer fluid to pass. In filtration, a soft porous paper is folded in the shape of a funnel, then placed into one; and, after suffering some water to filtrate through it, to dissolve the alum, usually employed in the manufacture of the paper, the liquor is to be gradually poured on, to pass through it.

When flannel is used it is commonly formed into a cone, called *Hippocrates' sleeve*, and its base is hung on three props, with the apex of the cone downwards; it is then filled with the liquor, which gradually drops from the apex: it is generally used when the fluid to be depurated is hot.

Distillation and sublimation are practised in the depuration of spirits and salts, and the operation is then called *rectification*.

DEPURATORIA FEBRIS, (from *de, and furus, pure*). DEPURATORY FEVER. A name given by Sydenham to a fever, which prevailed in the years 1661 and 1664. He called it *depuratory*, because he observed that nature regulated all the symptoms in such a manner as to fit the febrile matter for expulsion in a certain time, either by a copious sweat, or a free perspiration. See Sydenham's Works.

DERAS, and DERMA, (from *dega, degus, a sheep skin*). The title of a book in chemistry, treating of the art of transmuting base metals into gold. It is written on sheep skins; hence also DERMA.

DERBIA. See IMPETIGENES.

DERIVATIO, (from *derivo, to draw from; and from de, and rivus, a river*). DERIVATION. In medicine, when a humour cannot conveniently be evacuated at the part affected, and is attracted from thence, to be discharged at another place, it is called *derivation*: thus a blister is applied to the neck to draw away the humour from the head.

The doctrine of derivation and revulsion, as understood and explained by the ancients, is, in their sense of these terms, wholly exploded. By revulsion they meant the driving back of the fluids from one part to determine it to another. The only rational meaning that the word revulsion, as here applied, can have, is the preventing too great an afflux of humours to any part, either by contracting the area of the vessels, or diminishing the quantity which flows from them; the first of these intentions is answered by the application of repellents to the part; the last by bleeding and other evacuations. The great object of the older authors was, however, to derive from a part, by establishing a drain in a very distant one. Thus they applied sinapisms to the feet to relieve the head. The fallacy of this reasoning we have noticed under the article of CIRCULATION. Revulsion was a reciprocal term to derivation: for revulsion was, in their sense, made by deriving to a distant part. The language and the ideas remain, though the error has been often demonstrated. It means also the derivation of a word, deducing it from its original source.

DERMATOIDES, (from *derma, a skin, or leather, and εἶδος, likeness*). See DURA MATER.

DERMATOLOGIA, (from *derma, the skin, and λογος, a discourse*). A treatise on the skin.

DERMATO-PATHOLOGIA. The pathology or diseases of the skin.

DE'RTON, (from *deris, the skin, or covering*). See ABDOMEN, OMENTUM, and INTESTINA.

DESCENSIO, and DESCENSUS, (from *descendo*, to move downwards,) mean the gentle and moderate motion of the body, or of the fluids, downwards. The chemists call it *distillatio per descensum* when the fire is applied to the top, and all around the vessel, whose orifice is at the bottom, and the vapours consequently driven there. Liquifying salts by exposing them to the air, as in making the aqua kali, is also a sort of *distillatio per descensum*.

DESCENSO'RIUM, (from the same). See BOTUS.

DESE'SSIO, (from *de*, and *sedeo*, to sit down). Celsus uses this word for sitting on a close stool. DESURRECTIO is used in the same sense, q. v.

DESICCA'TIO, (from *desicco*, to dry up). DRYING. The chemists also refer it (though improperly) to calcination.

DESICCATI'VUM, (from *desicco*, to dry up). DESICCATIVE. See EPULOTICA.

DESIDIA OBLIVIO, (from *deses*, sloth, and *obliviscor*, to forget). That inactivity and forgetfulness which attend the approach of lethargy. See LETHARGUS, under CAROS.

DESIPIENTIA, (from *desipio*, to rave, or to doat). See PHRENITIS.

DE'SME, (from *δεω*, to tie, or bind,) a word which occurs in Moschion. A FAGGOT. See MANIPULUS.

DESMIDION, a diminutive of *desme*; a handful.

DE'SMOS, (from *δεω*, to bind up). In Hippocrates de Fractura, this word signifies an affection of a joint after a luxation, when, as if tied, it is rendered incapable of bending or stretching out, which proceeds from inflammation.

DESPUMA'TIO, (from *despumo*, to scum). See DEPURATIO.

DESQUAMA'TIO, (from *de*, privative, and *squama*, the scale of a fish). To take off scales. Sometimes it signifies the same as abrasio; and by a metaphor is applied to the separation of a foul bone, the laminae of which rise like scales; more properly termed EXFOLIATIO; which see. When the scarf skin peels off after some eruptive complaint, the process is named *desquamatio*.

DESQUAMATO'RIUM, (from *desquamo*, to scale off). An epithet of a trepan, called also *exfoliativum*, for abrading part of the cranium.

DESUDA'TIO, (from *desudo*, to sweat). See EPIDROSIS. It is also profuse sweat, succeeded by an eruption of pustules, called *sudamina*, *hydroa*, and *boas*: these are of the miliary kind.

DESURRE'CTIO, (from *desurgo*, to arise from). The same as DESESSIO; but, though the derivation of the two terms appears to be widely different, they have been used in the same sense, to go to stool. Castelli.

DETE'NTIO, (from *detineo*, to detain). See CATALEPSIS.

DETE'RGENS, (from *detergeo*, to wipe off). DETE'RGING. (See ABSTERGENTIA.) These were medicines formerly supposed to have a specific power in cleansing wounds; but it is now found that proper pus is the most healing application, and that foul sloughs are only separated by exciting the action of the vessels below them.

DETERIORA'TIO, (from *deterior*, worse). DETERIORATION. The impairing or rendering a thing worse.

DETERMINA'TIO, (from *determino*, to fix bounds

to). In botany it means the prescribed habit of an herb, as to the number of its leaves, their direction, or insertion, and from which it never deviates. In medicine, an increased action of the vessels of any part, and an accumulation of fluids in it.

DETERSO'RIUM, (from *detergeo*, to cleanse). The apartments at baths where the sweat was scraped off.

DETERSO'RIOUS, (from the same). See ABSTERSIVUS.

DETONA'TIO. DETONATION, (from *detono*, to make a great noise). In chemistry it is that noise and explosion which some substances make upon the application of fire, or rather sparks. Detonation is a less degree of thundering noise, and less explosive than *fulminatio*. (See CALCINATIO, by *detonation*). As nitre is the cause of most explosions, the word *detonation* hath been appropriated chiefly to the inflammation of this salt with inflammable bodies; and it is frequently given to those inflammations of nitrous acid which are not accompanied with explosion. Compositions have lately been discovered which detonate by percussion, or even the slightest friction. But this rather belongs to FULMINATION; q. v. See Dictionary of Chemistry.

DETRA'CTIO, (from *detraho*, to draw forth). See CATHARESIS.

DETRA'HENS QUADRA'TUS, (from the same). See PLATYSMA MYOIDES.

DETRA'CTOR AU'RIS, (from the same). See ABDUCTOR AURIS.

DETRI'TIO, (from *detero*, to rub off). In a general sense it is taken from *trituration*. See RHACOSIS.

DETRU'SOR URI'NÆ, (from *detrudere*, to thrust or squeeze out of). Douglas divides the muscular covering of the bladder into two distinct muscles: the muscle composed of longitudinal fibres he calls the *detrusor urinae*, which he describes as arising from the prostate gland going round the fundus, and being lost in the gland again; the oblique fibres form a muscle, which he calls *constrictor vesicae urinariae*, and describes as running obliquely under the other. But Dr. Hunter thinks this distinction merely artificial.

DE'UNX. See CYATHUS.

DEU'RENS FE'BRIS, (from *deuro*, to burn). See ARDENS FEBRIS.

DEU'STIO, (from the same). See ENCAUSIS.

DEUTE'RIA, and DEUTE'RINAS, (from *δευτερος*, secundus). A poor kind of wine, which the Latins call *lora*. Also an adhesion of the placenta.

DEUTE'RION, (from the same). See SECUNDINA.

DEVALGA'TUS, (from *de*, and *valgus*, bow legged). See BLÆSUS.

DEX'AMENE, (from *δεχομαι*, to receive). Any receptacle, but particularly the *labrum* or *folium*, that is, a deep basin in which bathers might swim. It was also called *colymbethra* and *embasis*.

DE'XTANS, (from the same). See CYATHUS.

DIA, δια. The beginning of several terms in medicine: and when the name of any thing begins with these three letters, they signify composition, and the word with which they are compounded is the chief ingredient in the composition. A variety of instances may be seen in the succeeding articles.

DIABA'CANU, (from *δια*, and *βακανον*, a principal ingredient in it.) An hepatic remedy mentioned by Trallian.

DIABE'BOS, (from βεβαιω, to strengthen). The ANKLE BONES. Hippocrates uses this word. See AS-TRAGALUS.

DIABESA'SA, (from δια, and βρασα, wild rue). The name of a preparation, in which rue forms a part.

DIABE'TES, (from διαβαινω, to pass off, or through). *Diarrhæa urinosa; dihsas; diuresis; hydrophs ad matulam; profluvium urinæ.* An excessive discharge of crude urine, exceeding the quantity drunk. Boerhaave, in his Institutes, says, it is a frequent copious discharge of lacteous urine, in conjunction with an extraordinary tenuity of the fluids.

Dr. Cullen places this genus of disease in the class *neuroses*, and order *spasmi*: which he defines a chronic flow of urine, made in immoderate quantities, and of a preternatural quality. He notices two species, 1st. *Diabetes mellitus*, when the urine hath the colour, odour, and taste of honey. 2d. *Diabetes insipidus*, when limpid only. Dr. Home defines it to be an extraordinary increase of the urine as to its quantity, and that of a sweetish taste, attended with perpetual thirst, and a dry skin, which for the most part is also scaly.

Youth is scarcely ever attacked with this disorder: its most frequent subjects are those in the decline of life, often those who have drunk liberally of wine in their earlier years, and who are also employed in the more violent kinds of business.

The flow of insipid urine is owing sometimes to a nervous irritation, and from this cause it appears to be occasionally a symptom of hysteria. It has been owing to relaxation of the kidneys from drinking mineral waters in excess, occasionally to unnatural indulgences, and, as has been said, to too great tenuity of the fluids: generally speaking, when permanent, it is a symptom of debility; when temporary, it is nervous. The insipidity of the urine is not always owing to a deficiency of its solid contents, but to their diluted state, from the large proportion of the menstruum. Yet in some fevers, apparently of the nervous kind, with affections of the head, we have perceived the salts almost wholly retained.

The other species is that which has lately attracted the greatest attention, the diabetes mellitus. In this disease the urine is not only copious in quantity, but wholly different in its quality, since it contains no animal matter, and yields, on evaporation, a considerable quantity of sugar. To constitute this disease, it is not necessary that the urine should be in an unusual quantity; since we find an instance where, in an anomalous consumption, the urine contained three ounces of sugar in a pint, without being uncommonly copious.

In general, in the diabetes mellitus, the skin is dry, parched, and often scaly. The appetite not greatly impaired; but the patient is weak and emaciated, with a low quick pulse. It has been said, that, on the stoppage of the discharge, anasarca has come on; but, in twenty cases we have seen, no such termination has occurred. It is, however, by no means a common complaint. The thirst is excessive.

In speaking of aliment, we have mentioned sugar as highly alimentary: the chyle and milk have been considered as abounding in sugar; so that, with some authors, the conclusion was easy, that the discharge was milky, with others that it was chylous. Modern che-

mistry, in ascertaining carbone to be the principle of vegetable substances, and azote of animal, has led with more reason to the conclusion, that the saccharine discharge was an imperfectly animalised fluid; and this idea is supported by the disease occurring in exhausted constitutions, while its chief remedies are tonics and stomachics. When we reflect on various symptoms of disease, we shall find that saccharine discharges are not uncommon. The depots lacteux of puerperal women are of this kind: in hectic we find the sputum occasionally sweet; we have found the saliva of a honied sweetness. Hippocrates has remarked, that the sweet smell and taste of the cerumen are a fatal symptom; and the colliquative sweats of hectic patients are occasionally found to impart the smell of acetous acid, after being confined in napkins. From these facts, our conclusion, that the *caliaca passio* may be a deposition of the same kind, will not appear very unreasonable.

Dr. Gottlieb Richter, professor of medicine at Gotttingen, thinks, according to his experience, that a diabetes is occasioned by a stimulus which acts upon the kidneys. When the particular irritation cannot be discovered nor removed, to counteract its action upon the kidneys by antispasmodics and sedatives, is the proper remedy. In proof of which he refers to Whytt and M'Cormic, who saw it originate from gouty matter, and Sydenham from healing an old ulcer. Steller, who cured a patient with bark and opium; Dobson, by warm baths; M'Cormic, by Dover's powder; Brisbane, by almond emulsion; support, in his opinion, the same doctrine. Dr. Richter says also, that tincture of cantharides and bark have been variously used with advantage against diabetes; and supposes, that the first acted by carrying off irritation, as in the chin cough; the second by allaying irritation, as in agues. But notwithstanding these, he depends chiefly upon his own experience, and gives some cures in support of his opinion: one case, which succeeded a bilious fever, wherein the pulse was small, tense, irritated, and quick, attended with an uneasy sensation and fulness in the region of the stomach; all the complaints growing worse towards evening, was cured by a vomit, by which a very great quantity of bilious matter was evacuated. A second, wherein some scorbutic symptoms appeared, was conquered by wort. A third and fourth, for which no precise cause could be discovered, yielded to tartar emetic and valerian in the first case; in the second, to ipecacuanha, which occasioned vomiting; and as often as the patient vomited, the disease disappeared for twenty-four hours: but besides these medicines above mentioned, he strongly recommends camphor in emulsion. See Medical and Surgical Observations, Edinburgh, 1794.

This author seems, however, evidently to confound the two species of diabetes; and after having mentioned his arguments and facts, we may safely conclude that they do not apply to the diabetes mellitus.

We know nothing of the process of animalisation, but that it is connected with the production or union of azote. The mode in which it is effected we cannot in this place ascertain; and all that the refinement of modern practice has suggested, with the assistance of the improved state of chemistry, is the exhibition of azotic substances with an animal diet.

The following remarks, which we transcribe from the

last edition, are apparently directed to the increased flow of limpid urine.

"The diet should be the same as in an hectic fever, viz. animal substances, such as broth made of beef, shell fish, milk often, and in small quantities; jellies, barley water, in which the root of comfrey is boiled, and lime water, may be the common drink.

"Moderate exercise on horseback, and dry friction of the whole body, assist in promoting perspiration; and which, when excited, peculiarly tends to divert the discharge through the kidneys.

"When unquenched lime is mixed with the serum of blood, it generates those salts that are necessary to the true urinary discharge; and if lime water is drunk as freely as the thirst requires it, its efficacy exceeds that of Bristol water in the cure of a diabetes, notwithstanding the latter is esteemed as a specific: but, in order to this advantage from lime water, it must be drunk while the heat continues, which it possesses from the lime being quenched in the water.

"At proper intervals, during the use of lime water, as above directed, the acidum vitrioli dilutum; cort. Peruv. limatura ferri; and whatever can improve the crisis of the blood, may also be administered.

"A flannel shirt may be worn, to solicit a discharge through the skin. The tincture of cantharides is said by Dr. Morton to be a specific in this complaint. Others prefer the serum aluminosum, made as strong as the stomach will bear it, and direct half a pint to be taken night and morning. With others, the vitr. cærul. gr. ss. given twice a day, dissolved in any agreeable liquor, is most depended on. When the means first proposed are unsuccessful, recourse may be had to these, or such other means as experience may suggest. Rhubarb is found to be of singular advantage; and from the success which follows on the use of antispasmodics, joined with other means, a spasm in the ducts, through which some other excretions are conveyed, rather than an irritation in the kidneys, may be a principal cause of this malady."

From these confident assertions the disease may be supposed tractable, and easily yielding. Each species is, however, peculiarly obstinate, and we fear both resist the best concerted plans. The hepatised ammonia (see CHEMISTRY) has failed in our hands; and the best, most successful, remedies have appeared to be bark, with Dover's powder, and a diet highly alkalescent and animalised. Yet, in general, every attempt has alleviated the disease only; for how can we expect to cure what is, perhaps, a symptom only of a broken constitution?

See Aretæus, Lommius, Boerhaave, Lister, London Medical Observations and Inquiries, vol. iii. p. 274, &c. vol. v. p. 298. Cullen's First Lines, vol. iv. Sydenham.

DIA'BOLUS META'LLORUM. See STANNUM.

DIA'BOLI INTESTINA. See CUSCUTA.

DIABO'TANUM, (from δια, and βοτάνη, an herb). The name of a plaster prepared of herbs.

DIABRO'SIS, (from διαβροσκω, to eat through). See ANASTOMOSIS, and ANABROSIS.

DIACA'DMIAS, (from δια, and καδμία, cadmia). The name of a plaster, whose basis is cadmia.

DIACALAMI'NTHEIS, (from δια, and καλαμίνθης,

calamint). The name of an antidote whose basis is calamint.

DIACA'RCINON, (from δια, and καρκινος, a crab, or cray fish). The name of an antidote prepared of these kinds of fish.

DIACA'RYON, (from δια, and καρυν, a walnut). See JUGLANS.

DIACA'SSIA, (from δια, and κασσία, cassia). See CASSIA FISTULARIS.

DIACASTO'RIMUM, (from δια, and καστοριον, castor). A name of an antidote whose basis is castor.

DIACATHO'LICON, (from δια, and καθολικος, universal). See CATHOLICON.

DIACELTATE'SSON. A name given by Van Helmont to a purging preparation of antimony. It seems to mean, in Paracelsus, a vomit excited by quicksilver. Sometimes this word signifies quicksilver dissolved in alcahest.

DIA'CENOS, (from δια, and κενος, empty, void). An epithet of porous bodies, as sponge, or pumice stone.

DIACENTAURI'ON, (from δια, and κενταυριον, centaureum). See CHAMÆDRYS.

DIACENTE'TON, (from δια, and κεντω, hungo, to prick). The name of a stimulating collyrium in Celsus.

DIACHALA'SIS, (from διαχαλω, to relax). A relaxation of the sutures of the cranium.

DIACHALCI'TIS, (from δια, and χαλκίτις, chalcitis). The name of a plaster whose basis is the calcitis.

DIACHEIRI'SMOS, (from δια, and χειρ, a hand,) is any manual operation.

DIACHELIDO'NIUM, (from δια, and χελιδων, celadine,) a swallow. A preparation of swallows.

DIACHETON. See ASPALATHUS.

DIACHORE'MA, and DIACHORE'SIS. The different excretions from the body; but more properly and frequently those from the intestines. See DISTRIBUTIO.

DIACHRI'STA, (from δια, and χριω, to anoint). Medicines applied to the fauces, palate, uvula, and tongue, to absterge phlegm, and discharge the mucus. P. Ægineta.

DIACHRY'SU, (from δια, and χρυσος, gold). The name of a plaster mentioned by Galen, used when limbs were fractured.

DIA'CHYLON, (from δια, ex, and χυλος, a juice). An emollient digestive plaster made of vegetable juices. The name is given to very different compositions for plasters, and is now the emplastrum lithargyri of the London Dispensatory. See EMPLASTRUM COMMUNE.

DIACHY'SIS, (from δια, and χυω, to fuse, or melt). See FUSIO.

DIACHY'TICA, (from the same). See DISCUTI-ENTIA, and DISSOLVENTIA.

DIACHY'TOS, (from the same). An epithet of wine prepared from grapes that have been dried seven days, and were pressed on the eighth.

DIACINE'MA, (from διακινεω, dimoveo, to put aside). See LUXATIO.

DIACLY'SMA, (from διακινεω, and κλυζω, to wash out, or rinse). See GARGARISMA.

DIACOCCYME'LO'N, (from διακινεω, and κοκκυμελον, a filum). See DIAPRUNUM.

DIACO'CHLACON, (from διακινεω, and κοκλακει,

*flints*). An epithet of milk in which red hot flints have been extinguished, supposed to be sudorific.

DIACO'DIUM, (from *δια*, *ex*, and *κοδεία*, a *foetus* or *head*). See PAPAVER ALBUM.

DIACOLOCYNTHIDOS PILULÆ. Alex. Tralian's composition which bears this name is called *pil. de nitro* in the Augustan Dispensatory: they consist of aloes, colocynth, nitre, &c.

DIACOLOCYNTHIS, (from *δια*, and *κολοκυνθίς*, *colocynthis*), from *colocynth*, which is the chief ingredient in the preparation.

DIACOMERON. The name of an antidote in Myrepsus.

DIA'COPE, (from *διακοπῶ*, to cut through). A deep cut, a wound, or the cutting off any part.

DIACOPRÆ'GIA, (from *δια*, *κοπρῶς*, *dung*, and *αἶξ*, a goat). A preparation with goat's dung against disorders of the parotids and spleen.

DIACRISIS, (from *διακρίνω*, to judge, or distinguish). The distinction of diseases and symptoms.

DIACRO'CIUM, (from *διακρίνω*, and *κρόκος*, *saffron*), also a collyrium containing saffron. The elect. de ovo; Platerus de curatione. Febrium Pestilentialium, tom. ii. c. 2.

DIACRO'CU, (from *κρόκος*, *saffron*). The name of a dry collyrium in P. Ægineta, in which saffron is an ingredient.

DIACURCUMA. Fuschius thinks Mesue used *curcuma* for saffron. A name of several antidotes in Myrepsus which contain saffron.

DIACYDONIUM, (from *δια*, and *κυδωνίος*, a quince). MARMALADE OF QUINCES. See CYDONIA.

DIADA'PHNIDON, (from *δια*, and *Δαφνίς*, the bay tree; bay berry). The name of a drawing plaster prepared from bay berries, employed to promote suppuration. Celsus, lib. 5, cap. 19.

DIADELPHIA, (from *δύς*, twice, and *ἀδελφός*, a brother). The name of the seventeenth class, in Linnæus's artificial system, comprehending those plants which bear hermaphrodite flowers, with two sets of united stamina. This is a natural class with papilionaceous, or pea flowers, and leguminous fruits. The orders are founded on the number of stamina; and ten being the predominating number in this class, the order *decandria* is much the largest. The regular disposition of the stamina in this order is, nine united in one brotherhood, the lower broad part of the filament sheathing the germ, and the tenth single; but in almost twenty genera, the ten stamens are connected into one body at the bottom.

DIADE'XIS, and DIADO'CHE, (from *δια*, and *ἐχόμεναι*, to transfer). See METASTASIS.

DIADO'SIS, (from *διαδίδωμι*, to distribute or dissipate). In medicinal authors it signifies to remit, though sometimes it means the distribution of the aliment over all the body.

DIÆ'RESIS, (from *διαίρειν*, to divide or separate). It is taken generally, from Galen, to be a solution of continuity, of which he forms four species, wounding, contusion, erosion, rupture; it is now used in this sense from whatever cause the solution arises.

DIÆ'RETICA, (from *διαίρειν*, to divide). Corrosive medicines.

DIÆ'TA, (from *διαίτω*, to nourish). *Dieta*, also *Diatericu*. DIET. When strict and regular, the Greeks

named it *cathestecus*. Though diet is often confined to what we eat and drink, yet Galen and most other medical writers include in it the whole of what are called the non-naturals.

We shall consider under this head what relates to our food and drink only.

We have already spoken at some length on this subject under the article of ALIMENT; and it will only be necessary, at this time, to distinguish the food adapted to the different ages, different climates, and to different periods of the day.

The food of infants is milk, mixed occasionally with the farinacea; and, in general, a healthy child requires no farther approach to an animal diet till after the ninth or tenth month. Yet, in some constitutions, the milk, from the mother's constitution, disagrees; sometimes the farinacea become acescent and flatulent. A more animalised diet is then necessary; and the juices of the younger animals, as of veal and chicken, must be mixed with the farinaceous pap. Sometimes the latter must be wholly laid aside, and the gravy of meat or beef tea substituted. With the teeth, new sensations arise, and the child is delighted to exert its little powers on what will easily yield; a bit of meat, some soft bread, &c.; nor, if he is healthy, is this to be forbidden. He advances another step, and makes a regular meal of solid food.

A growing child is always craving for food: his stomach digests rapidly no inconsiderable quantity, when his age and size are considered; and, if he is active and strong, there is no reason why he should not be indulged. We are told, however, that he should be fed regularly, at distant intervals, and in moderation. There seems no rule so little consonant to the dictates of nature. If the child grows full; if he breathes with difficulty; if he is torpid or drowsy; he is certainly over fed. But if from his meals he rises to play; if his sleep be light and uninterrupted, and his activity incessant; it is difficult to say what are the limits which a judicious observer would lay down for the regulation of his diet. The symptoms of fulness, which we have mentioned, are not seen when the food is plain; the drink, water; when pastry and confectionary are denied, or very sparingly allowed: nor have we ever observed a bloated infant, whose diet was properly regulated in its quality, whatever may have been the quantity. Nature never errs in her demands, when not pampered by high sauces, various dishes, or sweetmeats. It is certainly a proper rule, that the drink of children should be of the mildest kind, and almost exclusively water. Wine or diluted spirits, in any form except as a medicine, should be forbidden; but as, according to modern customs, it is sometimes impossible to comply with this rule, they should, at least, never be rendered habitual. Sauces and condiments should be equally strangers to their palates, till, at least, after the age of fourteen.

From eighteen to fifty-six, if moderation be observed, and the health good, no rules of diet are necessary: *sana omnia sana*. Yet we would suggest the propriety of making the meal, in general, on one dish only, either of fish or animal food. The little excesses in this respect, if not often repeated, will not be injurious; and we have already stated, that the powers of nature in preserving health and correcting any deviations are *lost*, if not occasionally exercised: we should add, that they are *exhausted* if the exertion is too frequent.

In this interval, the errors respecting drink are often more fatal than those which regard the food. Water with the meals is always most salutary: cyder follows; and beer, or porter, according to different constitutions, come in succession. Cyder is said to be injurious to those subject to rheumatism; beer is certainly so to the corpulent and asthmatic; porter is a salutary liquor, though containing a proportion of poisonous vegetables. If any thing be afterwards taken, wine will be preferable to spirits in any form. The quantity will vary in different habits; and, as the prior customs may have induced an artificial necessity, a pint of wine should be the utmost limit: in general, it should be less, and it may occasionally, though this should seldom happen, be more. Dr. Cadogan recommended, at times, intemperance. This is not, indeed, wholly inconsistent with the principle already stated; and if we sometimes break regularity, without, however, verging to intemperance, the danger will not be considerable. Midnight orgies are always fatal, for the fever at night is exasperated by wine, as well as by late hours.

When the second childhood commences, the habits of the earlier period of our lives return. Animal food is less easily borne. The lighter diet is preferred, and wine begins to lose its relish. Of the whole change, the diminution of the proportion of wine is most injurious; and the old man should drink it as a cordial, if not as a luxury. We ought, however, to add, that the growing distaste for wine is so common in advanced life, that we almost distrust our opinions in this respect. Yet we think experience supports them. The love of confectionary, of tarts, and whatever is sweet, returns also in old age; and this propensity we have never found injurious, though sometimes indulged with little moderation.

We have spoken of spirits as less wholesome than wine. It may be said, that by dilution they are not superior in strength, and may be even made of an inferior quality. In wine, however, there is an extractive matter, and a mucilage which sheaths the pungency of the spirit; but, independent of this difference, by distillation an oily matter is separated, which, from the action of heat, seems to acquire, if not an actual empyreuma, a deleterious quality. In a moderate proportion they are not, however, eminently hurtful; and we must repeat another axiom, that poisons differ from medicines not in their qualities, but their doses. It is often asked, which kind of spirit is the most wholesome. In the moderate quantities, we would allow they are perhaps equally so. Rum has been preferred as most oily. It is certainly not more wholesome on this account. Brandy is more suitable, in general, to weak, gin to disordered, stomachs; but the latter is always injurious, when any irritability or weakness in the urinary or neighbouring organs exists.

The diet, adapted to different climates, will not detain us long. Under a tropical sun, the perspiration is considerable, and the fluids alkaline. The supply should therefore be of the mildest kind, and the proportion of watery fluids large. Yet the languor produced by heat requires assistance for the digestive organs; and the tropical regions, which abound in succulent fruits, abound also in spices. On this subject we have spoken at sufficient length under the article of *CONDIMENTS*.

If the stranger to these regions, from this statement, indulges in fruits, he will find himself in error. Old

habits are not easily conquered; and the constitution will not change, at once, with the climate. The bile soon becomes more acrid; and this, with fruit in excess, occasions cholera or bilious fevers. Some proportion of the usual stimuli are also essential; and the spices, with a moderate proportion of wine, are at first necessary. When the constitution is more accustomed to the climate, he may indulge more freely; but excess in hot climates should be always particularly avoided.

We have explained, at some length, the effects of continued cold, and pointed out the torpor which it produces in every part of the system. Indulgence in animal food, in wine, and even in spirits, may in the arctic regions be more readily admitted. Indeed, seasoned dishes and wine are almost indispensable, especially if a person has been accustomed to them in more moderate climates.

Of the sixteen hours not destined to sleep, two hours may be dedicated to meals; and we think that nature would divide them in the following manner. After one or two hours from our rising we should breakfast; about noon, or soon afterwards, dine, allowing for this meal an hour, as we should take after it a little rest, but without sleep. The concluding slight meal may then be about an hour before bedtime. The first and last meal will require only an hour; and the more solid substantial one, with the respite from labour, we have said another hour.

This may appear to be a plan of peculiar severity; but the health, the cheerfulness which follow, will compensate for all the inconvenience. It is necessary, however, to explain its foundation. One substantial meal of solid animal food, each day, is sufficient to support the constitution under very considerable fatigue; and the time of taking this meal is undoubtedly about the middle of the day, or one in the afternoon. If the changes, even in the most healthy constitutions, are observed, three slight febrile accessions may be discovered. We style them febrile, though in general announced by an increased quickness of pulse only; but their nature is shown by their being sometimes attended with rigour and increased heat, in consequence of debility alone. The first of these occurs about eight in the forenoon, and it remits about ten; the second occurs at twelve, and remits about one or two; the third at six or seven, and is not completely at an end till two in the morning. The evening paroxysm is the most distinct; that at noon very inconsiderable. The period of the morning paroxysm distinguishes all fevers of the tertian type; that of the evening the quartans, which is also the type of continued fevers, for we have seen that they scarcely ever terminate till the quartan period has taken place. See *CRISES*.

These are the principles which regulate the time of taking food. The system of the healthiest person after sleeping, is not at once alive and active; and the appetite, unless from indulgence, or in childhood, is seldom craving at this early period. If the person rises at six, his breakfast hour should be eight; and if he is to experience great fatigue, some animal substance, as an egg, or some cold meat, may make a part of his meal, which will not require half an hour. If in health, the morning paroxysm is not noticed; and he may with this support continue till one, when the solid substantial meal should be taken; and the remainder of the hour, for the plain meal of a hungry man requires but little time,

should be destined to repose, while the fever, which digestion always produces, continues. The slight evening meal may be taken at eight, and the hour of repose should not be protracted beyond ten. The evening meal should be slight, because it is taken during the evening paroxysm; and the hour of retiring be early, that much of the time, while it continues, may be passed in a state least likely to increase it. It has been reported, we believe with truth, that a judge was accustomed to ask witnesses, who are often in a very advanced period of life, respecting their diet, &c. He found, it is said, that their mode of living was various, but that they uniformly agreed in early hours. Whether we have correctly stated the cause or not, it is, however, a fact, that nothing is more injurious than late hours, and that, in every instance, a *habit* of this kind shortens life.

It may be remarked, that in this arrangement of our time and meals we have been anxious to avoid the fever from indigestion interfering with the regular febrile exacerbations; and it may be asked, why may not the evening fever be obviated by retiring to repose before it recurs, or the morning paroxysm by remaining in bed till after it returns? The answer is easy: we are constituted for activity by day, and for repose by night; nor does sleep naturally come on so early as six in the evening. To this may be added, that exercise does not increase these slight febrile attacks, but the increased perspiration, which is its most frequent consequence, either prevents or lessens them. The other idea is apparently more plausible. After, however, the termination of the evening paroxysm, at one or two in the morning perspiration comes on, which gradually increases, though in no hurtful degree, till after six or seven. If therefore, continuing in bed *would* prevent the morning paroxysm, the injury to the constitution would be greater by the debilitating perspiration, which necessarily recurs.

We have engaged at greater length in this disquisition than we designed, as we wished to rescue a popular subject from the dictates of caprice, and the trammels of fashion; to point out what is right, if modern customs will not enable us to pursue it. We shall, therefore, next examine how far fashionable life is reconcilable to this system, and where the usual customs may be allowed as least injurious.

A modern day begins by far too late, and the stomach is at once cloyed by animal food before the system has recovered its activity and tone. The eggs, the dried fish, the tongue, or the ham, which in moderation might be digested by a constitution which has already laboured two hours, is a load on one, without exercise, exhausted by the morning perspiration, and yet languid from imperfect sleep. The lunch at one or two is the only part of the system which can be recommended. It is a plain solid dinner at a proper hour, sufficient to support, not overload. The subsequent dinner at six is superfluous. It is unnecessary as a principal meal, and too stimulating for a supper. Luckily, fashion spares the stomach any new load. The evening paroxysm thus excited is kept up by wine, and different stimulants, by crowded and hot rooms; nor does the constitution know a respite till the moment of retirement.

If we look at the waste which this excess of nourishment is intended to supply, we shall find it very considerable. If anxiety, restlessness, hope delayed, or

ambition disappointed, exhausts the frame, we fear in high life they are so frequent as to draw compassion even from the labourer, who eats his hard earned meal with cheerfulness, and rises, refreshed with sleep, to his daily toil. In general, however, the daily ride, and the daily saunter, are the chief exercises; and the votaries of fashion thus anxiously hoard all the diseases arising from repletion and indigestion for their future torment. These would be more striking, but that the summer carries them to the sea coast, where fashion allows of more air, more violent exercise, earlier hours, and less crowded apartments.

**DIÆTE'TICA**, (from *diæta*). See PHARMACEUTICE.

**DIAGLAU'CIUM**. The name of a collyrium recommended by Scribonius Largus. It is thus named from Glaucium, which, according to Dioscorides, is the juice of the *papaver spinosum*.

**DIAGNO'SIS**, (from *διαγνωσκω*, to discern, or distinguish,) also *dignotio*. It generally means distinction, and is generally confined to diseases; therefore, diagnostics mean the signs of diseases by which they may be known and distinguished. They are of two kinds, viz. the *adjunct*, and *pathognomonic*: the first are common to several diseases, and serve only to point out the difference between diseases of the same species; the latter are those which always attend the disease, and distinguish it from all others.

The knowledge of diagnostics has always been considered as of the greatest importance in the practice of medicine; and to know a disease is justly believed to be the first step in its proper treatment. The want of accuracy in distinction is a source of much uncertainty; and it is not uncommon for those who practise from the popular treatises, to apply the remedies recommended for one complaint to those of another; so very imperfect are such works in discrimination. Distinction is the greatest object of nosological systems; and this advantage we shall afterwards have occasion to point out. See NOSOLOGY.

**DIAGRY'DIUM**, also **DACRYDIUM**; which see. A preparation of scammony; but indeed the general name of the resin itself: quasi *δακρυδίων*, *lachrymula*, because the juice issuing from the wounded root was called *lachryma scammonii*. Its great activity was corrected by the ancient physicians by exposing it to the fumes of burning sulphur; in reality combining it with the vitriolic acid, and it is then called *diagrydium sulphuratum*. It is sometimes incorporated with the *spiritus vitrioli rosati*, sufficient to make a liquid paste, which is afterwards dried in the sun or by a gentle fire; called *diagrydium rosatum*; occasionally it has been baked in a quince: but all these modes are of not the slightest consequence as correctors; nor, indeed, does the medicine require correction. See SCAMMONIUM.

**DIAHERMODA'CTYLUS**, (from *δια*, and *ερμοδακτυλος*). A purging medicine, of which hermodactyls form the basis.

**DIAHEXA'PALA**, or **DIAHEXA'PTE**. See LAURUS ALEXANDRINUS.

**DIA'ION**, (from *δια*, and *ιον*, a violet). The name of a pastil in Myrepsus. Violets are its chief ingredient.

**DIA'IREOS**, (from *δια*, and *ιρις*, a lily). An antidote in Myrepsus, containing the lily root.

**DIALA'CCA**, (from *δια*, and *λακκα*, *lacca*). An antidote in the same author, containing lacca.

**DIALAGOU**, (from *δια*, and *λαγος*, *lepus*, a hare). A medicine, whose chief ingredient is the dung of a hare.

**DIALEPSIS**, (from *διαλείπω*, to leave a space between). To intermit. See **APOLERSIS**.

**DIAL'EANON**, (from —, and *λεανον*, *frankincense*). A name of several medicines in which frankincense is an ingredient.

**DIA'LOES**, (from —, and *αλοη*, the aloe). A composition in which is aloes.

**DIALTH'EA**, (from —, and *αλθεια*, the malton). The name of an ointment in Myrepsus, the prototype of the althæa ointment.

**DIALYSIS**, (from *διαλυω*, to dissolve, or render languid,) also *dissolutio*. A dissolution of the strength, or a weakness of the limbs; applied by Hippocrates to the cause of the debility, particularly of the winds, hence *οι διαλυηκοι*, *ausuri dissolventes*. It is expressive also of a discontinuity or division of a part.

**DIALY'TICA**, (from the same). A solution of continuity as in fractures, or wounds.

**DIAMARE'NATUM**, (from *δια*, and *αμυγενα*, *acid cherries*). It is a confection of acid cherries, called *amarantæ*, reduced to a pulp, passed through a sieve, then mixed with sugar, and aromatics. See Schroder. *Pharmacopœia Medico Chimica*, lib. 4, p. 41.

**DIAMARGARITON**, (from *δια*, and *μαργαριτης*, *pearl*). An antidote in which pearls are the chief ingredient.

**DIAMA'SCIEN**. See **ÆRIS FLOS**.

**DIAMASSETIA**, (from *διαμασσομαι*, to chew). A masticatory.

**DIAMBRE' PILULÆ**, from *δια*, and *αμβρα*, *amber*). See **AROMATICÆ PILULÆ**.

**DIAMBRE' SPECIES**, **SPECIES AROMATICÆ**, now **PULVIS AROMATICUS**. The prescription is originally Mesue's, and had its name from the ambergrise in the composition. See **AROMATICÆ SPECIES**.

**DIAME'LON**, (from *δια*, and *μελον*, a quince). The name of a composition containing quinces.

**DIA'MNLS**, and **DIAPNE**. An involuntary and insensible discharge of urine; a word used by Joannes Anglicus.

**DIAMORON**, (from *δια*, and *μαρον*, a mulberry). A preparation of mulberries and honey.

**DIAMO'SCIU**, (from *δια*, and *μοσχος*, *moschus*). The name of an antidote containing musk.

**DIAMOTO'SIS**, (from *δια*, and *μοις*, *lint*). See **CARBACES**.

**DIA'NA**. The chemical, or rather alchemical, name of silver. See **ARGENTUM**.

**DIANANCA'SMOS**, (from *δια*, and *αναγκη*, *force*, or *necessity*). The forcible restitution of a luxated part into its proper place. Hippocrates gives this appellation to an instrument intended to restore a distorted spine.

**DIA'NDRIA**, (from *δς*, and *ανδρ*, a man). The second class of Linnaeus's artificial system, comprehending all hermaphrodite flowers which have two stamina.

**DIA'NTION**, (from *δια*, and *ανθος*, a flower). The name of an antidote in Galen, which is thus made.

*R. Fior. rosarum ʒi. rosarum rubrarum et radice glycyrrhizæ ʒā ʒi. Caryophyllar. aroniat. spicæ nardi*

*nucis moschatæ radicis galangal. corticis cinnamomi radicis zedoariæ ligni aloes seminum cardam minoris sem. anethi. et anasi. macis. ʒā ʒi. m.*

**DIA'NTIUS CARYOPH'LLUS**. See **CARYOPH'LLUS RUBER**.

**DIAOPO'RON**, (from *δια*, and *οπωρα*, an autumnal fruit). A composition of quinces, medlars, and services.

**DIAPA'SMA**, (from *διαπαζω*, to sprinkle). See **CATAPASMA**.

**DIAPEDE'SIS**, (from *δια*, through, and *πηδω*, to pass). The transudation of blood through the coats of an artery, or occasionally between its fibres. See **ANASTOMOSIS**.

**DIAPE'NCIA**. See **ALCHIMILLA**.

**DIAPE'NSIA**. See **SANICULA MAS.**

**DIAPE'NTE**, (from *δια*, and *πεντε*, *quinque*). A composition which consists of five ingredients; gentian root; aristolochia longa; shavings of ivory; bay berries: *bac. laur. et myrrh. ʒā p. æq. m. f. pulv.*

Mesue is said to be its author; but Vegetius described it before him. It is now only used by farriers.

**DIAPEPE'REON**. An antidote mentioned in Galen.

**DIAPHÆ'NICON**, (from *δια*, and *φοινιξ*, a date). The name of an electuary for discharging phlegm; as well as a medicine made of dates.

**DIAPHILEDO'NU**. The name of an antidote in Myrepsus.

**DIAPHLY'XIS**, (from *διαφλω*, to moisten). In Galen's Exegesis it means effusions or ebullitions; also an affusion, or moistening any part.

**DIAPH'ORA**, (from *διαφωρα*, to differ). **DIFFERENCE**. In medicine it comprehends the characteristic marks and signs which distinguish one disease from another. It also signifies a corruption of food in the stomach; and is then synonymous with **DYSPERSIA**; which see.

**DIAPHORE'SIS**, (from *διαφορεω*, of *δια*, through, and *φερω*, to carry). See **PERSPIRATIO**.

**DIAPHORE'TICA**, (from the same). **DIAPHORETICS**. Medicines which promote perspiration. Diaphoretics differ from sudorifics: the former only increase the insensible perspiration; the latter excite a sensible discharge through the skin, which is called *sweat*. See **SUDORIFICA**.

Diaphoretics are those medicines which produce a discharge from the surface; and when this discharge is fluid, they are styled *sudorifics*. The true diaphoresis is a condensed halitus, distinguishable by a moist clammy feel; while the diaphoe, of which we have had occasion to speak, and to which we shall often return, seems still less sensibly moist, and to be more truly gaseous. This is ascertained by the peculiar softness of the skin in health.

These three states have been supposed to differ only in degree. The insensible halitus, when in a quantity to be condensed, and in this state sensible to the feelings, is the diaphoresis: and this, when more decidedly fluid, sweat. The same causes, in different degrees, appear to produce each discharge; and they have of course been supposed to proceed from the same vessels, the exhalant arteries. If the distinction were a refinement merely, it would not deserve a moment's notice. We think, however, that it involves many questions of

practice. We cannot relieve some complaints without actual sweating, and others are injured by it. Rheumatisms require the former discharge, and fevers demand its regulation, at least, if not the reduction of its violence. Again: diaphoresis, if gradually increased to sweating, can scarcely in any instance be kept up after it. When the sweating is stopped, the skin is dry, and shivering often follows. If, in diaphoresis, we feel the hand, it is soft and unctuous to the touch: in the most violent sweat, the skin, though covered with moisture, often feels harsh and unyielding in its substance beneath. Sweating almost constantly requires increased heat, or the confinement of the heat of the body. Diaphoresis, on the contrary, is often produced by antimonials and different sedatives. We shall admit that these distinctions may, with a very slight exertion of ingenuity, be reconciled with different degrees of the action of the same vessels; yet, while practical facts lead us to distinguish them in their effects, we were willing to point out some discordance in their phenomena. It is no objection that anatomy does not furnish us with a clue in this investigation, by demonstrating the glandular apparatus. We have no such structure to explain the production of sweat; and the best physiologists consider it as an exhalation from the serous arteries, while others suppose it to be derived from follicles under the skin, though no such have been demonstrated. Sweat, in a chemical view, differs little from the serum of the blood. It contains, with a large proportion of water, some gluten and muriated ammonia; while the insensible perspiration consists of carbonic acid gas, with a proportion of azotic gas. In some experiments, it has appeared to be chiefly the latter. The acid which occasionally appears on the sweat, is the phosphoric. We have much reason to believe, then, these discharges to proceed from different vessels; and should conclude, that the halitus is a secreted fluid in a gaseous form, while the sweat is only elicited by the force of the circulation from the exhalant arteries. We are confident, however, that these opinions, should they be found or appear fanciful, will not mislead. The distinction which we shall pursue is wholly practical; and, as it was originally suggested by practical facts, we hope it will contribute to elucidate and explain them.

Perspiration has been styled insensible, from its not being cognizable by any sense. Its existence is ascertained by the peculiar softness of the skin, and the general feeling of freedom and hilarity which accompanies this state of health. It is the diapnoe of some authors; but in Chenot, this term rather means a slight degree of diaphoresis. The discharge of insensible perspiration is an halitus not admitting of being condensed in a fluid form, of the nature already explained.

The diaphoresis is an increased discharge of a vapour rather than a gas. It is obvious to our sight, when a sun beam passes over the surface of the body, while naked against a wall, as a slight shade may be perceived. It is usually the effects of warmth, of a stimulus, or of exercise; and is felt by a warm healthy glow, and a sensation of freedom from oppression or inconvenience.

Sweating, on the contrary, is probably a serous discharge from the skin, generally attended with considerable warmth, often with oppressive heat, seldom affording a pleasant sensation, unless associated with mirth

and hilarity, as in dancing, or a freedom from pain, as in the sudorific treatment of rheumatism.

These different discharges are excited by different means. The diapnoe is the criterion of health, and we can restore it only by restoring health. Diaphoresis and sweat are excited by different ways, which may be divided into the stimulant and relaxant. The stimulant diaphoretics are chiefly heat, sometimes alone; occasionally assisted by aromatics, and similar heating medicines. We employ sometimes heat alone to produce sweat, as in the sudatoria of the ancients; heat, in other circumstances, is communicated more successfully by vapour and by water, though their relaxant power contributes to the effect: it is communicated also by solid bodies, as bricks or tiles, heated cloths, bottles and jugs containing warm water. The heat of the body itself is sometimes confined for the same purpose, and a partial diaphoresis kept up, by covering any portion of the body with oil skin;—a general sweat by additional clothes, particularly flannel, whose properties we have already explained. See COOPERTIO.

Heat produces this discharge, when conveyed to the stomach by means of warm water; and it is rendered more effectual when this water is impregnated with different stimuli. The aromatic herbs of our own country, and the spices of the warmer regions, are equally employed for this purpose. Wine, cyder, sometimes beer, ardent spirits, and volatile alkali, are occasionally added to increase the effect; but these always operate with great stimulus and inconvenient heat.

It was formerly the custom to accumulate all these stimuli for particular purposes, thinking that the greater the heat, the more copious would be the discharge. Physicians, in this plan, were frequently disappointed by their own eagerness. They could produce burning heat, and a clammy fluid on the skin, which appears to be the serosity, with a large proportion of the gluten of the blood; but they soon found that this was not of the nature of sweat, nor so efficacious as the more fluid discharge. We were brought nearer the truth by Dr. Alexander, who found, by his experiments, that the temperature of the body must be often reduced before the proper discharge takes place. The temperature, at which sweating most freely occurs, he fixes at 108° of Fahrenheit. We have found, by some experiments, that this heat is too high, and suspect the accuracy of his thermometer. We are confident that the highest point is 102°; and that generally the heat, when the sweat is most free and salutary, does not exceed 100°.

To this reduction of temperature, rather than to its increase, we must attribute the effects of many diaphoretics. A draught of cold water will often, in this way, excite a free diaphoresis; and cold affusions, during the height of the febrile paroxysm, will have the same effect. We have striking instances of this kind in the practice of Dr. Currie and Dr. Gregory in scarlatina. Acid drinks have a similar power; and to this cause we attribute the diaphoretic effects of vinegar whey, the whey of milk, and similar drinks.

There is, however, a class of stimulant diaphoretics which act more gradually, and almost insensibly, by mixing with the blood, and stimulating, in the course of their circulation, the extreme vessels. From what has been observed under the article of ARGENTUM

*vivum*, it will be obvious that mercurials are remedies of this kind, and we are inclined to refer all the metallic tonics to the same head. Arsenic will probably be found a similar remedy. There are many vegetable substances which may be referred to this class, particularly the *serpentaria contrayerva*, the *mezereum*, and the *guaiacum*. The *seneka*, which may appear to belong to it, owes, more probably, its diaphoretic effects to the action of vomiting which it excites.

To these more moderate stimuli of the extreme vessels, some of the gentler exercises may be added. Sailing, riding in a carriage, and swinging, require bodily exertion in the same order; but are apparently similar in their effects of determining to the surface. Riding on horseback, walking, dancing, digging, tennis, and ringing, require still more violent exertion, and at last excite copious sweat.

External stimulating diaphoretics are, friction, rubefacients, warm plasters of Burgundy pitch, euphorbium, and cummin seeds; and blisters, which excite copious partial perspiration, previous to their vesication.

The relaxing diaphoretics are much more powerful in their operation; and at the head of this list is opium. There are few ancient sudorifics which have not this medicine as an ingredient in a greater or less proportion; and of whatever nature the diaphoretic is, the addition of opium makes it more active and successful. Antimonials are equally useful, and *ipécacuanha* scarcely yields to them in this power. It has been doubted, whether these two last medicines act independently of the nausea they produce. We have little hesitation in thinking that they do so, for their effect is not in proportion to the degree of nausea, and is sometimes considerable, when no such previous power is obvious. Squills seem to connect the nauseating medicines with those which act on different principles. No diaphoretic effects are strikingly produced by them in moderate doses; but it may be presumed that such exist, by the balance observable between the skin and kidneys; for whatever may excite the discharge from one organ, if its operation is prevented, stimulates the other. Vomiting constantly relaxes the vessels on the surface, and every medicine which produces it is a diaphoretic. The whole tribe of narcotic vegetables, with their deleterious effects, produce cold sweats. Yet these we should not employ as salutary medicines; though we suspect that the *aconite*, and some others, employed in chronic rheumatism, or that hybrid disease which seems to connect gout and rheumatism, act in no other way.

Such are the remedies employed as diaphoretics, and such, in general, the principles on which they act. We must now attend to their effects on the animal economy.

The connection between the state of the extreme vessels, the system in general, and the stomach, has been already noticed. This has been attributed to a nervous sympathy, and probably is owing to such a connection, since the effect is more sudden than can be explained in any other manner. To keep up the action of these vessels must consequently be always of the greatest importance, since health is inconsistent with a contrary state; and, in the whole circle of acute and chronic complaints, no single circumstance requires greater attention.

When we reflect, however, on the extent of the surface of the body, we shall find, that to fill the extreme

vessels will require no inconsiderable proportion of the fluids. To prevent, therefore, as well as to relieve, internal congestions, this class of remedies is of the greatest utility. If, however, carried to excess, no evacuation so greatly debilitates; and though all secretory organs, after their action has been violently excited, sink into a torpid state, the vessels of the skin seem peculiarly disposed to this alternation of inactivity after exertion. If then it is intended to relieve congestion, we must be peculiarly cautious to excite no greater action than we can constantly keep up. In all such cases, therefore, the slightest diaphoresis is only admissible. In fact, we should fill the vessels, instead of promoting any considerable evacuation.

As different theories have dictated, we have been sometimes alarmed with apprehensions of producing morbid viscosity and lentor of the fluids by sweating; at others, taught to promote this evacuation to counteract preternatural tenuity. Each danger is equally imaginary. When sweat is excited, other watery discharges are proportionally diminished, and thirst leads the patient to require a supply. On the other hand, tenuity of the blood, when it exists merely in consequence of an increased proportion of water, is relieved by the kidneys, without any effort on our side. When it arises from an increase of the ammoniacal salts in the blood, the debility which attends prevents the use of remedies which, in any degree, weaken the system. In those cases where acrimony may be suspected, (they are indeed very rare,) violent, insatiable thirst calls for a supply of watery fluids for their solution and evacuation. They are then eliminated through the urinary organs. We must next consider the diseases to which diaphoretics are applicable.

The insensible diapnoe, we have said, is the criterion of health, and can be produced only by supporting the general healthy state. It is most observable in cold weather; and the nearer we approach to it in every disorder, the greater is our success. It is generally obtained by free cold air, when this is admissible; and to attain it is our aim in every complaint.

The moderate diaphoresis is our chief object in the greater number of acute diseases. To begin, as usual, with the *pyrexia*, we may remark, that diaphoretics are, in this class, of very extensive utility. *Intermittents* are usually left to their course during the paroxysm, and the efforts of the physician are reserved for the interval. Yet there are circumstances in which the return of the paroxysm would be fatal; and others, where the delirium, in the hot fit, is most alarming. In each case, diaphoretics are employed: in the first, to support the circulation in the extreme vessels, that the fit may be obviated; in the second, to hasten the natural crisis by perspiration. The kind of diaphoretics chosen for the first purpose, is the warm stimulants; the reason of which we shall afterwards explain. To assist in promoting perspiration, in the hot fit, the relaxants, and particularly opium, are preferred. This was the practice introduced by Dr. Lind.

In *continued fevers*, it was, for ages, the custom to give the most stimulating diaphoretics to promote the concoction of morbid matter. Not a breath of air was suffered to approach the patient; but *serpentaria*, *contrayerva*, and volatile alkali, were exhibited in profusion.

We have been assured, that three beds have, in succession, rotted by the sweat, under the same person, in a single fever. We still attempt to promote perspiration; but by cooling, rather than heating, remedies, adapting them to the circumstances and to the temperature of the patient. Modern practice has freely adopted the relaxant diaphoretics, particularly the antimonials, to conquer the supposed spasm on the surface. We trust that we shall show that this plan has at least been carried to an improper extent, even if it appear well founded in its principle.

In the *phlegmasiæ* the skin is hot and dry, and the utility of diaphoretics is obvious. As the temperature of the skin is above the sweating point, cold is chiefly indicated; yet, in many of the diseases, this plan cannot, for reasons already assigned, be carried to a considerable extent (see *COLD*). We must, therefore, adopt the relaxant diaphoretics; and of these we are often obliged, for other reasons, to avoid opium. Antimonials are then our chief dependence, with the other remedies peculiarly adapted to the seat of the complaint. There is, however, one disease, which is an exception to these general remarks; rheumatism. After the more active period of the complaint, it admits of the more stimulating diaphoretics; and when the fever has abated, of the most stimulating. In fact, after a time the vessels become torpid and paralytic, to be roused only by the most powerful exciting causes; but this state can only be explained under the proper head, after many previous distinctions. See *INFLAMMATIO* and *RHEUMATISMUS*.

In the *hæmorrhagiæ* we find little room for diaphoretics, except of the most cooling kind. The source of their utility in relieving internal congestions has been already explained; but it will be obvious that these remedies are chiefly of service in active hæmorrhages, where the heat is preternaturally increased. In this case, cold drinks and cold applications are, as usual, the most powerful diaphoretics. In the passive hæmorrhages they relax too powerfully to be of the slightest utility. In reality, they are highly injurious.

*Exanthemata*. The diseases of this order peculiarly require the use of diaphoretics; but, in the greater number of genera, the heat is already beyond the point which admits of a discharge from the skin, so that the more cooling medicines of this class are preferred, except in one genus, the *measles*. In *scarlatina*, the cold affusions, long continued, have been found of singular utility in promoting perspiration. In the plague, the gentle diaphoresis called by Chenot the *diapnoë*, is found of the greatest utility; and it appears probable, from the late experience in this complaint, that this is best obtained by cold. To this general doctrine there are only two exceptions, either when the disease is of a putrid nature, or the eruption has disappeared. In these cases warmth of every kind is essentially necessary, and the warmer diaphoretics are only employed.

In the *profluvia*, this class of remedies is of the highest importance. In the only two diseases included under it in the best system of nosology, diaphoretics chiefly relieve. In *catarrh*, their use is well known; and in *dysentery*, when purgatives have evacuated the accustomed scybala from the intestines, the ipecacuanha and antimonials, so universally recommended, undoubtedly act only by determining to the surface.

In the first order of the *NEUROSES*, the *comata*, diaphoretics are not peculiarly indicated. Yet we must keep in our view the advantages which, in every case of internal congestion, arise from keeping the extreme vessels in an active state, since they contain so considerable a portion of the fluids. Of the *adynamiæ*, *dyspæxia*, *hypochondriasis*, and *chlorosis*, require the same attention. In each there is always a defect of perspiration; and, in each, to restore it, contributes greatly to the patient's relief.

Of the *spasmi*, *tetanus* chiefly demands our attention to the state of the skin, as it often proceeds from cold, and is relieved by active sweating. When mercurials, with opiates are of such singular service, the benefit probably originates from the same source. In *asthma*, the utility of diaphoretics is sufficiently obvious, from what we have already said; and in *colic* and *diarrhæa* external warmth is singularly useful. In *cholera* they are of peculiar service; and Sydenham has remarked, that every remedy to calm the vomiting has failed, till a sweat broke out. We mention this more particularly, as the advantages of these remedies were not duly enforced under the proper head.

Of the *vesaniæ*, *melancholia* alone seems to be particularly relieved by diaphoretics; yet, in those cases of *mania* where there is great internal congestion, could the patient be properly confined, they might be useful. In the *CAEXIÆ* we see little foundation for their peculiar employment. In each genus, however, the circulation in the extremities is particularly languid, and the external stimulating diaphoretics are of use. Of the *IMPETIGENES*, the diseases merely cutaneous are benefited by them; but these require the more gently stimulating kind, which act steadily rather than violently: we mean the mercurials, the sarsa, the mezereon, and the others enumerated.

The chief disadvantages of diaphoretics arise from their debilitating effects. The discharge, therefore, in every instance, should be conducted with caution and moderation; nor should the practitioner aim at relieving his patient rapidly, when the cure would be safer and more permanent, were the course more gentle and steady; and when the perspiration has been kept up with violence, relapses are by no means uncommon.

**DIAPHRAGMA**. The *diaphragm*, (from *διαφρασσα*, to make a partition, or inclosure, of *δια*, and *φρασσα*, to close,) because it divides the cavity of the thorax from that of the abdomen. *MIDRIFF*; also called *diazoma*, *disseptum*, *hyfiozoma*, *septum transversum*, *cinetus*, *succingens membrana*, *discrimen thoracis et ventris*. Pliny calls it the *præcordia*, because it stands, he says, like a wall, to defend the heart. Hippocrates, with many of the ancients, call it *φρεγες*; they also gave the name of *diaphragma* to the division between the mouth and the œsophagus, terming it, by way of distinction, the *diaphragma per œsophagum*. Galen and Rufus Ephesius call the cartilaginous partition between the nostrils, the *diaphragm* of the nose; but the only part now called *diaphragm* is that first mentioned.

The *diaphragm* is composed of two muscles; the small one rises by two tendons, called *crura*, from the second lumbar vertebra, and receives a slip from the first vertebra of the loins, and from the ligament which joins the last rib to the vertebra; the two *crura* then run upwards and grow fleshy. The large muscle rises

from the inside of the margin of the thorax, all round, from the false ribs to the xiphoid cartilage; its fibres shoot forwards, and form that triangular appearance called the *centrum tendinosum*, or *centrum nervæum*. Winslow calls it the *middle aponeurosis*, or *aponeurotic plane of the diaphragm*: M. de Bordeu calls it *centre phrenique*; and it is also called *costrum*. There is a notch between the crura of the lesser muscle where the aorta passes. In the larger muscle are two passages, one in the tendinous part, for the vena cava, which is situated there; because as the tendon is not capable of being contracted, the circulation will not be interrupted: the other is for the œsophagus, and is situated in the fleshy part. The reason seems to be, that the diaphragm, in its action, pressing upon the stomach, might cause an evacuation of its contents, unless at the same time it constricted the cavity of the œsophagus. If this be true, the diaphragm has probably little effect in promoting the action of vomiting. From considering the attachment of the diaphragm, it will be seen that its action will be to render itself flat, and thereby to enlarge the cavity of the thorax; but if we regard it as acting round the viscera as round a pulley, we may conceive how it both depresses the viscera and raises the ribs; at the same time still more enlarging the cavity of the thorax. Its veins are large, and go directly to the vena cava. The arteries are sometimes immediately from the aorta, and sometimes from the cœliac; a few branches are received also from the lumbales and adiposæ. The nerves are from the plexus cervicalis on each side, and from the second pair of the vertebræ.

In inspiration, the diaphragm descends towards the belly; this is its proper motion resulting from muscular contraction. In expiration, it is relaxed and drawn upwards, forming a concavo-convex figure, the concave side being towards the belly. It assists in the expulsion of the excrements and fœtus. It is in perpetual motion, and seems to have other and more important uses in our constitution than as yet are clearly understood. It is also a name of the *septum scroti*. See SCROTUM.

DIAPHRAGMA'TICÆ ARTE'RIÆ, belonging to or connected with, the diaphragm. The DIAPHRAGMATIC ARTERIES; also called *phrenicæ*. Their origin has been already explained. The diaphragmatic arteries generally appear on the under side of the diaphragm, very rarely on the upper; they give small branches to the glandulæ renales, and to the fat which lies on the kidneys; these latter are called *adiposæ*. Besides these capital diaphragmatic arteries, there are other less ones from the intercostales, mammariæ internæ, mediastinæ, pericardiæ, and cœliacæ.

DIAPHRAGMA'TICÆ VE'NÆ, (from the same). The DIAPHRAGMATIC VEINS; also called *phrenicæ venæ*. They spring from the vena cava inferior, just as it descends through the diaphragm: they appear generally on the lower side of the diaphragm. The left branch is ramified upon the pericardium.

DIAPHRAGMA'TICÆ SUPERIORES VE'NÆ. The UPPER DIAPHRAGMATIC VEINS, are also called *pericardio-diaphragmaticæ venæ*. The right comes anteriorly from the root of the bifurcation, near the mediastina, and is spread about the pericardium: the left from the left subclavian.

DIAPHRAGMI'TIS, (from *διαφραγμα*, *diaphragm*).

INFLAMMATION OF THE DIAPHRAGM. See PARAPHRENITIS.

DIA'PTHORA, (from *δια*, and *φθίγω*, *corrumptio*, *to corrupt*). In Hippocrates it signifies the corruption of the fœtus. See ABORTUS.

DIAPHYLA'CTICOS, (from *διαφυλασσω*, *to keep*). See PROPHYLAGE.

DIA'PHYSIS, (from *διαφω*, *internascor*, *to grow between*). An interstice, a partition, or whatever intervenes between different parts. Galen explains it to be a nervous and cartilaginous protuberance in the middle of the junction of the os tibiæ with the os femoris, which enters that large sinus, and separates the lower heads and processes of the os femoris, inserted into the sinus of the tibia. This substance only appears in recent subjects. In other places, the diaphysis is spoken of as a cavity, or chink, for the reception of some other part.

DIAPISSELÆ'ON, (from *δια*, and *πισσαλαιον*, *the oil of pitch*). A composition in which liquid pitch is a chief ingredient.

DIAPLA'SIS, (from *διαπλассω*, *to put together*, or *fashion*). CONFORMATION. It signifies the replacing a luxated or fractured bone, as near as possible, in its proper situation.

DIAPLA'SMA, (from *διαπлассω*, *to smear over*). An unction or fomentation applied all over the body.

DIA'PNE, (from *διαπνεω*, *to pass gently through*, as the breath does). See DIAMNES.

DIAPNOE, (from *διαπνεω*, *to perspire*, from *δια*, *through*, and *πνεω*, *to breathe*). See PERSPIRATIO, and DIAPHORETICA.

DIAPORE'MA, (from *διαπορεω*, *to be in doubt*). Anxiety, heat, and restlessness, in distempers. See ALYSMOS.

DIAPRA'SIUM, (from *πρασσιον*, *horehound*). A composition in which horehound is one of the ingredients.

DIAPRU'NUM, (from *δια*, and *προυνον*, *a prune*), also called *diacoccymelon*. The name of two compositions which contain prunes: both are purging electuaries; but the elect. è sennâ is used in their stead.

DIAPSO'RICUM, (from —, and *ψωρα*, *the itch*). The name of a medicine for the itch or scurvy.

DIAPTE'RNES, (from —, and *πτερινα*, *the heel*). A medicine made of the heels of animals and cheese.

DIAPTERO'SIS, (from —, and *πτερο*, *a feather*). The cleaning of the ears with a feather.

DIAPYE'MA, (from —, and *πυον*, *pus*). See ABSCESSUS.

DIAPYE'MATA, and DIAPYE'TICA, (from *διαπυημα*, *a suffuration*). See SUPPURANTIA.

DIA'RIA FE'BRIS, (from *dies*, *a day*). See EPHEMERA.

DIAROMA'TICUM, (from *δια*, *aroma*, *aroma*). A medicine composed of aromatics.

DIA'RRHAGE, (from *διαρρηγνυμι*, *to break asunder*). A fracture, particularly of the temporal bones.

DIARRHODOME'LI, from *δια*, *ροdon*, *a rose*, and *μελι*, *an apple*). The name of a composition of scammony, juice of roses, &c. See DIAGRYDIUM.

DIARRHO'DON, (from —, and *ροdon*, *a rose*). A name of many compositions in which roses are ingredients.

DIARRHŒ'A, (from *δια*, *through*, and *ρεω*, *to flow*). ALVI FLUXUS, *hyperædosis*; *perturbatio alvi*; a too

frequent discharge of the contents of the intestines. Dr. Cullen places this genus of disease in the class *neuroses*, and order *spasmi*, which he defines a frequent purging; the disease not contagious, and unattended with any primary febrile affection. Of this he forms six species: 1st, *Diarrhœa crafulosa*; *stercorosa*, seu *vulgaris*; when the excrements are more fluid and more copious than is natural. 2d, *Diarrhœa biliosa*; when yellow fæces are copiously discharged. 3d, *Diarrhœa mucosa*, *leucorrhœis*; *diarrhœa lactantium*; *serosa*; *pituitaria*, vel *mucosa*; in which, either from acrid substances taken into the stomach, or from cold applied particularly to the feet, there is a copious discharge of mucus. 4th, *Diarrhœa celiaca*, called also *celiaca chylosa*, and *lactea*; when a milky liquid, like chyle, passes downwards. 5th, *Diarrhœa lienteria*; when the aliment soon passes through, with little alteration. 6th, *Diarrhœa hepaticrhea*; when the discharge is bloody coloured serum, and not attended with pain. If painful, it is sometimes called a colic.

Those who have been rendered weak or irritable by a hot season or sultry climate, or by being exposed to a putrid vapour, are peculiarly liable to this disease.

The immediate cause is irritation in the intestines; but the causes of this preternatural irritation are numerous: the most frequent are an undue use of purgatives; acidity, or putrescency of the aliments; acrid bile; pus absorbed from abscesses, and carried to the intestines; a laxity of the glands of the intestines; obstructed perspiration; putrid vapours; a translation of the morbid matter of other diseases to the intestines; passions of the mind, &c.

Whatever other symptoms occasionally attend a diarrhœa, besides a too copious and too frequent discharge of the intestines, are accidental. The loss of appetite, and of strength, are consequences of the excessive evacuations, or of some other attending disorder; sickness and pain are, in many cases, only attending symptoms. While the patient's strength is but little affected by a diarrhœa, it may be generally looked on a salutary rather than morbid evacuation; but sometimes, if neglected or ill treated, the cure is difficult.

Diarrhœa, in its most unlimited sense, is a discharge from the bowels; and, in this view, its explanation is peculiarly difficult. The principal distinction which arises is, whether the cause be connected with the bowels, or with other organs; in fact, whether diarrhœa be idiopathic or symptomatic. But this distinction we shall have little occasion to employ, since the greater number of instances are owing to substances actually present in the intestines.

The most obvious species is that kind which arises from the ingesta, whether these in their quantity or quality offend. In either case, the first symptoms arise in the stomach; and, if the patient cannot ascertain the fact from recollecting what he has eaten, he may be reminded of it, by the taste arising in his mouth, the aversion which he feels on recollecting any part of his former diet; from the nidorese eructations, resembling the taste of rotten egg, or even a putrid taste on the back part of the tongue. In such circumstances, no medicine will, in general, succeed, without evacuating the stomach; but to this consideration we must return.

When the ingesta pass the stomach, they sometimes excite commotions from their action in the intestinal canal. They then usually pass off; but there are in-

stances where they are retained, particularly in the colon, by a spasmodic constriction; and the increased action which they excite is sometimes continued from increased irritability alone. In the first instance, considerable pain usually attends; in the second, the stools are watery, without pain.

Another kind of diarrhœa, confined to the bowels, is from an increased discharge of the fluids poured in from their excretory ducts. The principal fluid is bile; and diarrhœa arises from this fluid in many different circumstances. An increased flow of bile is sometimes owing to continued heat only, and it is then attended with vomiting, as in cholera; sometimes from a previous obstruction of the biliary ducts, when the preceding jaundice will point out its cause; occasionally from the exciting passions of the mind; from the bites of vipers; from worms; from poisons; from congestions in the liver; from cold; or the cold fit of fevers.

Of the other glands whose ducts open in the alimentary canal, we have a less perfect knowledge. The pancreas only is an object of our sense, and its functions are little known. It is probable, however, that its fluid resembles the saliva; and, when we find mercurials employed in friction, instead of affecting the salivary glands, stimulate the intestines, we naturally ascribe it to an increased discharge of the pancreatic fluid.

The whole of the canal is covered, however, with mucous glands; and we know that, when the perspiration is obstructed, the whole mucous membrane compensates for the defect, by an increased discharge. It is said, and, we believe, with some truth, that the milk is occasionally absorbed and deposited on the intestines; we can add, after what has been said on the subject of *CÆLIACA PASSIO* and *DIABETES*, q. v. that the unapplied aliment sometimes takes the same course.

In cases of teething, we might consider the increased action of the salivary glands as similar to the increased discharge from the pancreas. We omitted mentioning it, however, under this head, because it is supposed that the irritation communicated through the whole membrane contributes to the effect. We dare not either deny or confirm this opinion; but it receives some support from opium being the most effectual remedy.

In cases of diarrhœa following suppressed perspiration, we considered the discharge as merely vicarious. It is, however, sometimes inflammatory; and it was necessary to separate the consideration in a practical view, from the following circumstance. A diarrhœa sometimes follows measles, which, Sydenham tells us, cannot be suppressed by the usual remedies, but by antiphlogistic plans, and particularly bleeding.

Diarrhœa, we have said, arises from acrid poisons; and these, even when they have been discharged, leave the intestines in so irritable a state, that even the common ingesta excite violent and irregular action. Sometimes even extreme general irritability will occasion a similar effect; and any agitation, even from the depressing passions, will occasion copious discharges from the bowels.

This disease occasionally attends fevers, and is said to be sometimes critical, which means, in the language of the ancient physicians, that the concocted morbid matter is thrown out by the glands of the intestines, probably the liver. Though we admit neither of the theory nor of the comment, the fact is certain, and will be found to admit of a different explanation. We now mention it merely to say, that, if in fever the pulse becomes

fuller, softer, and slower, the skin more moist, without faintness, though the discharges by stool are copious, they should not be hastily checked.

The bowels suffer from another cause. When internal suppuration takes place, the discharge is sometimes lessened, and the purulent matter apparently evacuated from the intestines. It is seemingly absorbed, and again deposited. In cancers we have more than once known this metastasis, as it is called, to take place; and in phthisis it is not uncommon, especially when there is no morning perspiration, or this discharge disappears, or is checked. It frequently attends peripneumony, and is then a dangerous symptom, as it prevents the natural solution of the disease by expectoration; sometimes it attends gout, when it brings back an almost extinguished paroxysm.

Diarrhœa sometimes continues long without evacuating the offending substance. We must not, therefore, conclude, from its continuance, that the intestines are properly emptied. In fevers it supervenes, or is produced by the most active purgatives, without properly discharging the contents of the canal, which only appear on the solution of the disease. When diarrhœa has long continued, it is attended with tenesmus, an irregular action of the rectum, suggesting the idea of a discharge impending, without effect. Sometimes the abraded mucus exposes the small vessels, and a little blood is evacuated. It is then said to be dysenteric; but no two diseases are more essentially distant than diarrhœa and dysentery, as we shall soon demonstrate. The mucous diarrhœa approaches most nearly to dysentery; but this is either owing to acrid cathartics or sometimes to cold.

Diarrhœa is seldom fatal but in exhausted constitutions, where it is generally a symptom of some highly dangerous disease; or where the tone of the intestines is so completely destroyed, that the aliment cannot be retained a sufficient time to be digested. In general, when it has continued for a long period, it is seldom completely removed; and, in such cases, when it has ceased for a time, the slightest occasional causes have induced a relapse.

The cure of diarrhœa is sometimes easy; but it frequently baffles our utmost skill. When the symptoms, already described in the stomach, lead to a suspicion that irritation is kept up by acrid substances in that viscus, an emetic should be premised. This, indeed, is generally necessary in every case where the diarrhœa continues obstinate. It relieves the stomach from acrimony, checks the increased peristaltic motion downward, gives it an opposite direction, or determines it to the skin: in each way it is useful. After the emetic, it is necessary to procure some respite, and opiates may be employed with safety. By lessening or stopping the peristaltic motion, we relax any spasmodic stricture which may prevent the discharge of offending matter; and the gentle laxatives afterwards required, will have a more salutary effect. By thus alternating the opiates and laxatives, we at last succeed in relieving the bowels from the irritation of offending matter, and moderately warm astringents will complete the cure.

The bilious vomiting will be sufficiently understood by what has been observed under the article CHOLERA. We can only add in this place, that while the dis-

charges continue dark and fetid, no astringents should be employed, and we can only allow occasional rest by a slight opiate after it, and the laxatives must be soon repeated.

When a bilious diarrhœa has followed a suppressed evacuation of bile, or when it arises from passions, from worms, the bites of poisonous animals, &c. it requires regulation, rather than immediate suppression, and we may still alternate the opiates with the laxatives; but emetics are unnecessary. The diarrhœa, from congestions in the liver, attends those who have lived long in, and been affected with the bilious diseases of, warm climates. It is a symptom of infarcted liver, and the cure will depend on the removal of the principal complaint. When from the congestion, in consequence of the cold fit of fevers, we must endeavour to relieve the fever by the remedies to be afterwards pointed out.

The diarrhœa, which arises from mercurials externally applied, we have attributed to their action on the pancreas; and the medicine must, in that case, be permitted, opiates employed, and perspiration excited by warm diluting liquors. When the kindred fluid, the saliva, excites the action of the intestines, in the teething of children, we can only lessen it, and diminish the irritation by opium. It must, however, be recollected, that a diarrhœa in teething is most salutary, and that it should be regulated, not checked.

The most frequent cause of diarrhœa is an affection of the mucous membrane, either when its action is increased to supply, with the other glands, the deficiency of perspiration, or when, from this or a specific virus, as in the measles, these glands are inflamed. In such cases the ipecacuanha, either in active doses, as an emetic, or in milder ones, with opium, as a diaphoretic, is of considerable service. The warm bath also, general or topical, is essentially useful. In the last case, Sydenham recommends bleeding; but by regulating the discharge only by diaphoretics, and interposing mild laxatives, we have always succeeded in combating it. In general, diarrhœa, from cold, should be treated like a catarrh, which it really is; and we may be less anxious to keep up any action of the bowels than in the other cases. A similar disease arises from the metastasis of milk, of any unassimilated nourishment, or of purulent matter. These also may be checked; but the offending fluids will find their way by other excretories, and little advantage can be gained, unless the original cause be removed. In the instance of the milk only can we form any reasonable expectations. This is the diarrhœa that attends puerperal women, and we should be cautious in checking it, though we must equally prevent its excess. In these cases the ipecacuanha, as an emetic, followed by the columbo root, and the careful, but occasional, exhibition of opium, will best succeed. Every means must, however, be attempted to bring back the milk to its natural channel.

When the diarrhœa is chronic, moderate astringents and tonics, warm feet, exercise on horseback, and avoiding the depressing passions, afford the most reasonable expectations of relief. Opiates, with demulcents, as in the old pulvis è bolo cum opio, the modern pulvis è cretâ compositus cum opio, are often essentially necessary.

The safest astringents in diarrhœa are the opiates, especially if joined with ipecacuanha. The tormentil, the ca-

techu, the gum kino, the oak bark, and the logwood, may be occasionally employed. We have placed them nearly in the order of their strength; for the tormentil is seemingly the strongest. The logwood appears to owe its utility, in part, to its mucilage, and is more effectual where the mucous coat of the intestines is abraded. In such cases, which often follow the use of acrid cathartics or poisons, this, with thick gruels, chiefly of rice, a decoction of althæa, with gum arabic, and every other mild demulcent, is of singular utility.

Opiates may be sometimes given in clysters, and they are said to affect the head in a less degree than when swallowed. They relieve more certainly, in this way, the troublesome tenesmus; which is often greatly mitigated also by the pulv. è bolo cum opio, interposing the mildest laxatives, as soap or castor oil.

Soap, when joined with wax, which thus becomes soluble in our fluids, is often highly useful when the mucus of the bowels is abraded, or tenesmus is troublesome. A little opium, and occasionally the Dover's powder, joined with these remedies, renders it more effectual.

It may be remarked, that we have not mentioned rhubarb, on which former authors seem to have a considerable dependence in this complaint, from its supposed subsequent astringency. We have not found it, however, superior to other purgatives: yet occasionally, in small doses, it seems to strengthen the bowels; and those who depend on its astringent qualities may supply this remedy, where we have mentioned purgatives in general.

See Aretæus; Lommius; Wallis's Sydenham; Fordyce's Elements, part ii.; Dr. Pye's Observations on the Use of Ipecacuanha, in the London Med. Obs. and Inq. vol. i.; Cullen's First Lines, vol. iv.

DIARRHŒA CARNO'SA. See DYSENTERIA.

DIARRHŒA CHOLE'RICA. See CHOLERA MORBUS.

DIARRHŒA URINO'SA, OR EX OUERE. See DIABETES.

DIARROX'Æ, (from διαρρησσω, *disrumpio*). The interstices betwixt the circumsolutions of bandages.

DIARTHRO'SIS, (from δια, *per*, and αρθρον, *a joint*). A MOVEABLE ARTICULATION; *abarticulatio*, and *dearticulatio*. Different authors vary in their division; but Dr. Hunter supposes it to consist of three species: 1st, The *enarthrosis*, or ball and socket; when a large head is received into a deep cavity, as the head of the femur into the acetabulum of the os innominatum: its synonym is *genou*. 2dly, *Arthrodia*; when a round head is received into a superficial cavity: these two kinds admit of a motion on all sides. 3dly, The *ginglymus*, called also *cardo*, *cardinamentum*; because it resembles the motion of a hinge. There are properly but two species of this articulation; the first confined to flexion and extension, the *angular ginglymus*, where each bone receives partly, and partly is received by the other, as in the articulation of the humerus with the ulna, or where the joint is adapted only to small turns towards each side, the *lateral ginglymus*. This last is either single, as in the articulation of the first vertebra of the neck, with the apophysis dentiformis of the second; or double, that is, in two different parts of the bone, as in the articulation of the ulna with the radius.

DIASPO'NIUM, (from δια, and σαπν, *soapi*). An ointment in which soap is a principal ingredient.

DIASATY'RION, (from δια, and σατυριον, *satyrion*). An electuary containing satyrion.

DIASCI'LLION, (from δια, and σκυλλα, *the squill*), vinegar and oxymel of squills.

DIASCI'NCI, (from δια, and σκινχος, *skink*). A name for Mithridate, which originally contained this kind of lizard. See CONFECTIO DAMOCRATIS.

DIASCO'RDIIUM, (from δια, and σκορδιον, *scordium*), from containing scordium, formerly called *elect. è scordio*. Hieronymus Fracastorius first described it; and it was named *Fracastorii confectio*; though now rejected from the London Pharmacopœia.

DIA'SENA, (from δια, and *sena*). It is an antidote in Myrepsus, containing senna; but very different from the pulvis è sena now in use.

DIASE'RICOS, (from δια, and σιρικον, *silk*). A composition in which silk is an ingredient.

DIASMY'RNON, or DIASMY'RNES. A name of several collyria, which contain myrrh (συμνη), called also *euelhidium* and *atheniphon*.

DIASO'STICA, (from δια, and σωζω, *to preserve*). See PROPHYLACE.

DIASPE'RMATION, (from δια, and σπερμον, *a seed*). A name of two malagmas, compounded of seeds.

DIA'SPHAGE, (from διασφαζω, *to separate*). An INTERSTICE. The interval between two branches of a vein. Hippocrates.

DIASPHY'XIS, (from δια, and σφυζω, *to strike*). The pulsation of an artery.

DIA'STASIS, (from διαστήμι, *to separate*), signifies the distance betwixt the fractured ends of bones receding from each other; also the natural interstice betwixt the radius and the ulna. Sometimes it signifies that distention of the muscles which happens in spasms. When this word is applied to the stomach, it means an effort to vomit; and when to the pulse, it is synonymous with diastole. It sometimes means a luxation.

DIASTE'ATON, from δια, and στεαρ, *fat*). The name of an ointment containing the fat of a stag, a sow, a goose, and a hen.

DIA'STOLE, (from διαστέλλω, *to stretch*). In anatomy, it imports the dilatation of the heart, auricles, and arteries; in contradistinction to systole, by which is understood their contraction. In the diastole the artery is enlarged both in length and breadth. In the systole the coats of the arteries restore themselves by their elasticity, assisted by the action of the muscular fibres. The diastole is performed almost instantaneously, the systole more gradually, insomuch that the latter employs two-thirds more time than the former. When the heart begins to vibrate, the diastole is the first motion. The heart has only two motions, dilatation and contraction; but it has been supposed to have a third, or subsultory motion, by which the blood is projected forward from the ventricles of the heart into the large vessels. This idea is, however, unfounded.

DIASTOMO'TRIS, (from διαστομω, *to dilate*). It is usually joined with μηλη, *a probe*. See SPECULUM.

DIASTRE'MMA, and DIA'STROPHE, (from διαστρεφω, *to distort*, or *turn aside*). A distortion of the limbs.

DIASU'LPHURIS EMPLA'STRUM, (from δια, and sulphur, *brimstone*). This is a prescription of

Rulandus; but it contains only a very small proportion of sulphur, with wax, &c.

DIATA'MARON. See ANTIMOROS.

DIATA'SIS, (from διατείνω, to stretch out). The extension of a fractured limb, in order to its reduction.

DIAECOLI'THOS, (from δια, and τηκολιθος, the Jew's stone). An antidote in which is the lapis Judæicus, called τηκολιθον.

DIATERE'TICA. See DIÆTA.

DIATE'SSARON, (from δια, ex, and τεσσαρες, four,) a compound made of four ingredients, viz. gentian, bay berries, myrrh, and the root of birthwort, in equal quantities. See DIAPENTE.

DIATE'TTIGON, (from δια, and τετλιξ, a grass-hopper). The name of an antidote containing grasshoppers.

DIA'THESIS, (from διατιθημι, to dispose). An affection, or a disposition, expressive of a particular state of the constitution. Hence the term, often used in medicine, *inflammatory diathesis*, that is, when the vascular system is in an inflammatory state, or so disposed as readily to be inflamed by any accidental cause. See HEXIS.

DIATRAGACA'NTHI SPE'CIES, (from δια, and τραγακανθος). See GUM. TRAGACANTHA.

DIATRINSA'NTALON. A confection in which is the santalum.

DIA'TRION PIPERE'ON SPE'CIES, (from δια, and τρεις, tres). A powder prescribed by Galen, which chiefly consists of three peppers.

DIATRI'TOS, (from the same.). An abstinence during three days was first recommended by the methodic physicians. The term was called *diatritos*, not the abstinence; and, from this circumstance, the methodics had the name of *diatritarii*. On the third day they gave such medicines as they thought of importance. Cælius Aurelianus gives this name not only to the term, but to the third day in particular.

DIAU'LOS, (from δια, twice, and αυλη, a station). A kind of exercise in which the person runs a straight course forwards and back again.

DIAZO'MA, (from δια, and ζωννυμι, to surround). See DIAPHRAGMA.

DIAZO'STER. A name of the twelfth vertebra of the back; called from ζωστηρ, the belt, which rests on it.

DICENTE'TON. See DIACENTETON; the name of a collyrium described by P. Ægineta.

DICHA'LCON. A weight equal to one third of an obolus.

DICHA'STERES, (from διχαζω, to divide). See INCISORES.

DICHOPHY'IA, (from διχα, double, and φυν, nascor). It is a distemper of the hairs, when they split at the points.

DICHO'TOMUS, (from διχα, double, and τεμνω, seco). In botany it means forked.

DICHOTOPHY'LLON, (from διχα, double, and φυλλον, a leaf). See CERATOPHYLLUM.

DICO'CTA, (from δια, bis, and coguo, to boil). Water first heated, then cooled with snow.

DICOTYLEDON'ES, (from δια, twice, and κοτυλεδων, cotyledon). See COTYLEDON.

DICRÆ'US, (from δια, twice, and κρινω, to distinguish). See BIFIDUS.

DICRO'TUS, or BIS-FERIENS, (from δια, twice, and κρουω, to strike). A pulsation of an artery which strikes the finger a second time before the usual interval, similar to what appears from a hammer striking the anvil, and afterwards rebounding. Solano first observed it, and supposed it a certain sign of an approaching critical hæmorrhage from the nose. It is also called a rebounding pulse.

DICTAMNI'TES, (from δικταμνος, dittany). A wine medicated with dittany.

DICTA'MNUS ALBUS, (from Dictamnus, a city in Greece, on whose mountains it grew,) *fraxinella*, WHITE OR BASTARD DITTANY. It is a plant with leaves resembling those of the ash tree, but much smaller, and more juicy. On the tops of the stalks are long spikes of purplish and white flowers, which are followed by pods of black seeds. It is perennial, and grows wild on the mountains in France, Italy, and Germany. *Dictamnus albus* Lin. Sp. Pl. 548.

The roots are whitish; the cortical part, freed from the pith and small fibres, is dried, rolled up, and in this form brought to England. The young roots, about the size of a squill, are the best. When fresh, they have an agreeable smell, dissipated in drying; are considerably bitter; a quality they yield to water and spirit, and which remains in the extract. Formerly this medicine was considered as efficacious in uterine and visceral obstructions, as well as an anthelmintic. But it had been neglected, till brought again into notice by Stoerck, and recommended in tertians; against worms, particularly the lumbrici; and menstrual suppressions. A scruple of the powder was given twice a day, which may be gradually increased to ʒi. From twenty to fifty drops of the following tincture were successfully prescribed in epilepsies, given two or three times a day: R. Dictamni albi recentis ʒij. sp. vini rect. ʒxiv. digere. In choleric patients, the root, mixed with steel, has been said to be efficacious. It is not, however, employed in this country, and probably is of little efficacy.

DICTA'MNUS CRE'TICUS, VERUS; *origanum Creticum*, ONITIS, DITTANY OF CRETE, OR CANDY WILD MARJORAM. It is the *origanum dictamnus* Lin. Sp. Pl. 823, and is a small shrubby plant, with square stalks, and roundish leaves, that are covered with a thick white down; the flowers are in spikes of a purplish colour. The flowery tops were formerly brought from Crete, and indeed these are somewhat stronger than ours, which are now always used. It is perennial, a native of stony grounds, and bears the winters of our climate. Those we have from Greece, when we receive them, are not greatly superior to our own.

Whilst the leaves are in perfection, they are warm and aromatic, have an agreeable smell, and a hot pungent taste, resembling that of the thymus citratus. The garden pennyroyal is of the same quality, but not equally strong. Both water and spirit take up the virtues of this plant. If a large quantity is distilled at once with water, a small portion of essential oil is obtained, of a yellowish colour, a highly pungent, aromatic taste and smell; congealing in the cold, so as to resemble camphor: the remaining decoction, when inspissated, is a bitterish, disagreeable mass, but destitute of the flavour and warmth of the herb: the spirituous extract possesses all its virtues. See Neumann's Chem. Works; Lewis's Mat. Med.

DICTYOIDES, (from *δικτυον*, a net, and *ειδος*, form). NET LIKE. See RETE MIRABILE.

DIDYME, (from *διδυμος*, double). See BIFOLIUM.

DIDYMÆA, (from the same). The name of a cataplasm mentioned by Galen, named from the double use to which he applied it.

DIDYMI, (from the same). See GEMINUS, TESTES, and CEREBELLUM.

DIDYMUS, (from *δισ*, or *δυο*, two). A TWIN. In botany it means double, or having two of each sort.

DIDYNA'MIA, (from *δισ*, twice, and *δυναμις*, power). Linnæus's fourteenth class, comprehending those plants which have hermaphrodite flowers, with four stamens, in two pairs, of different lengths, the outer pair longer, the middle pair shorter, and converging. These flowers have one pistil, and the corolla is irregular. Linnæus has divided this class into two orders, *gymnosperma*, and *angiosperma*; the seeds naked or covered.

DIECBO'LION, (from *δια*, and *εκβαλλω*, to cast out,) a medicine causing abortion: hence DIECBOLICA.

DIELE'CTRON, (from *δια*, and *ελεκτρον*, amber). The name of a troche, in which amber is an ingredient.

DIERVILLA. *Lonicera diervilla* Lin. Sp. Pl. 249. This species of honeysuckle is a native of the most northern regions of America, and its young branches are employed in gonorrhœa and suppression of urine.

DIET DRINKS. Alterative decoctions, employed daily in considerable quantities, at least from a pint to a quart. The decoction of sarsaparilla and mezereon, the Lisbon diet drink, is the most common and most useful.

DIETETICS. The doctrines relating to diet.

DIE XODOS, (from *δια*, and *εξοδος*, a way by which any thing passes). *Diodos*. In Hippocrates, it is the descent or passage of the excrements by the anus.

DIFFLA'TIO, (from *difflo*, to blow away). See PERSPIRATIO.

DIFFU'SUS, (from *diffundo*, to spread out). DIFFUSE. In botany it means spreading wide.

DIGA'STRICUS, (from *δισ*, double, and *γαστρικ*, a belly). See BIVENTER.

DIGE'STIO, (from *digero*, to dissolve). DIGESTION. In surgery it is the disposing an ulcer or wound to supuration, by the application of proper remedies.

In pharmacy it is the subjecting of bodies, included in proper vessels, to the action of a gentle heat. The term digestion is often used for maceration; and, in this case, the process is without heat: where this circumstance is not expressed, digestion always implies the operation of heat. In some cases, digestion is used to produce a change in a single body, as in hydrargyrus nitratus ruber; in others, to promote solutions, or different combinations. Circulation is a mode of digesting: the vessels generally used are matrasses, or Florence wine flasks, either of which may be converted into circulatory vessels; or the neck of one may be inverted into the neck of the other. The operation is generally performed in a sand bath, by which the degrees of heat may be regulated according to the intention of the chemist. This heat is never so great as to make it boil. Digestion is used for making tinctures, wines, and elixirs.

In the animal economy, it is the conversion of aliment into chyle, and then into blood. By digestion, the specific differences of all substances are abolished; the blood, formed from different kinds of aliment, whether used singly or together, does not sensibly differ in

its properties, provided that the organ of digestion be sufficiently powerful to convert them into blood. Digestion, in the stomach alone, is capable of converting our food into chyme, and the continuation of the process can alone assimilate it to our own nature.

This function of the animal economy is of most difficult explanation. The ingenuity of physiologists has been exhausted in the solution of the problem; and we are still at a distance from any theory that will explain all the different appearances satisfactorily.

When, with Hippocrates, we attribute digestion to putrefaction; with Pringle and Macbride, to fermentation; or, with Haller, to the joint action of solution and fermentation; we alter the language only, not the opinions. Van Helmont attributed it to the energy of his archæus, which resided in the stomach; and, though fanciful in language, we shall probably find this process very intimately connected with the vital principle. We must, however, premise some peculiar circumstances in the structure of the parts concerned in the operation, omitted in the general descriptions; because they would appear more advantageously, when their application could be at the same time perceived.

The alimentary canal extends from the mouth to the anus, enlarged at different parts, to detain the food, and assist the changes it is destined to undergo. When the œsophagus passes down on the left side, the canal crosses the body; and we here find the first dilatation, which we style the stomach. In its empty state it appears a bag, into which a substance falls, and from which it must rise to pass out at the other aperture, the pylorus. When, however, the stomach is full, the fundus of this sac is raised against the integuments, and it assumes the form of a crescent. The angle to which the substance passing out must rise, in the empty state, is obliterated; but the food is retained by the contraction of the strait fibres, which draw the pylorus towards the cardia. The fundus of the stomach enlarges between the folds of the epiploon, which is its mesentery; and the large vessels of this membrane are thus emptied, discharging their contents into the stomach, which receives also, at the same time, blood, from its pressure on the spleen, which determines a larger proportion of the vital fluid through the vasa brevia.

The next dilatation is a little below the stomach, at the part styled the duodenum. The intestine, in this part, is not confined by the peritonæum so closely as to form a mesentery; but is loosely connected to the back bone, and admits of considerable distention. Here the chyme receives the bile and the pancreatic juice; and, in this part, its animalisation begins, and chyle is formed. The intestines then proceed, of an uniform diameter, till the end of the ilium is inserted, in the manner before described, into the large intestine (see COLON), where it again stagnates; apparently to admit of the absorption of the remaining chyle.

The food of animals is very various; yet it consists only of a few principles, and these may be reduced to oil, gelatine, and sugar, with the animal matter already prepared. In proportion as the food is of the last kind, its remora in the stomach and duodenum is shorter; but the digestion of matter already animalised, is a problem too simple to detain us. We must remark, however, that the action of the stomach differs from almost every known power. It has no effect on living bodies: its

effects are in proportion to the vital energy; and when this is greatly diminished from any sudden cause, the digestion suffers at the same moment, and in the same ratio. Digestion sweetens also, in a short period, the most putrid substances which the stomach can retain. So different is this process, as well as its instruments, from every other, that we must turn with contempt from the philosophers attempting to imitate it in their phials, did not their exalted character in other pursuits change our contempt to surprise.

The changes produced by digestion are very considerable. The principles of vegetable substances, as we have already seen, consist of oxygen, carbone, and hydrogen; animal substances contain the same principles, with a less proportion of carbone, and with the addition of azote. The production of the azote has occasioned the chief difficulty; for we know that some proportion of carbone is separated with oxygen, by respiration, in the form of carbonic acid gas. We must, however, pursue the subject in its proper order.

The changes in the stomach are, by the most modern physiologists, attributed either to fermentation or solution. Each, however, gives a due share of the credit to the division by mastication, combination with the saliva, the effects of heat, and gentle agitation in the stomach by the action of its fibres, producing a regular progressive and retrograde motion. Fermentation, it is contended, does not probably take place, because we do not find its productions, an ardent spirit, and an acid. We have more than once had occasion to remark that we often find an acid, which we know to be the product of fermentation, though we cannot detect the previous form. We discover, in digestion, an extrication of air, which, when the process is not interrupted, is again combined with the mass, and an acid is perhaps always formed; because, when by accident digestion is disturbed, or stopped, in an early period, it is obvious. In better circumstances this acid disappears, in consequence of a subsequent union. In short, as our vegetable food is susceptible of fermentation, and in circumstances which would most probably favour it, we see no reason for denying that this change takes place.

Those who contend that digestion is a simple solution, have sought, with some anxiety, for a solvent of a peculiar power; and they have at last, apparently, discovered it in what they style the gastric juice, a mucous fluid always found in the stomach, of some peculiar, but no very decisive properties. It is, undoubtedly, a solvent out of the body; but the experiments made by forcing animals to disgorge what they have taken, prove the power of all the fluids of the stomach, not of one only. In every part of the human body, the production of a fluid of peculiar powers is connected with a complicated apparatus. In the stomach the mucous glands only seem to produce the gastric juice. When analysed, it is said, by Struve, to contain a phosphorated ammonia; but this conclusion has not been supported by other chemists. Carminiati digested some veal in water, with a little salt, in a heat of about 100 of Fahrenheit. The decanted liquor he employed in a similar experiment, which he repeated till he produced a fluid resembling the gastric. This would lead us to a suspicion that the gastric juice is only the remnant of former digestions, and, in reality, nothing more than a ferment. We are told, however, by Carminiati himself

(Journal de Physique, vol. xxi.), that the gastric fluid of herbivorous and of carnivorous animals, when the stomach is not organically diseased, assists digestion, and cures intermittents, if given as a medicine. Other authors have told us, that it is antiseptic; that it even sweetens putrid meat; and that it greatly assists in healing old ulcers. It is natural to suspect the existence of extraordinary qualities, when detailed by those who, previous to their experiments, had formed a particular system. We may just suggest, however, that if the gastric juice has such miraculous powers, why does it not constantly produce them in the stomach? If, after a meal made with the best appetite, a cause of sudden agitation or of deep distress should occur, the food, which would have otherwise produced wholesome chyle, becomes acid or putrid. The stomach is not, therefore, a containing vessel only, gently agitating the mass.

Fordyce, after describing the structure of the organs of digestion; the matters applied to the food in those organs; and pointing out that the substances employed for food have the same elements, and each of them all the elements, actually found in chyle, viz. a part which is fluid, and contained in the lacteals, but coagulates on extravasation:—a second, which consists of a fluid coagulable by heat, and, in all its properties that have been observed, consonant to the serum of blood; and a third, formed of globules, which render the whole white and opaque; observe, that it was, therefore, only necessary that these elements should be separated from one another, and recombined in order for its formation. That the action of the organs of digestion disunited the elements of the food, which were reunited in a new form, so as to form the essential parts of the chyle; and that these three essential parts of the chyle were always the same; and, therefore, when converted into blood, the blood *à fortiori*, could not, in the smallest degree, be influenced by the food. The elements, according to this author, are separated in the stomach, where they are retained; but the chyle is not formed in this organ. A simple matter, called *chyme*, is only there produced, which in the subsequent state of the process is, by the reunion of its elements, formed into chyle.

Digestion consists of two distinct stages: the first, which takes place in the stomach, styled solution, or fermentation; and the second in the duodenum, which is more strictly animalisation. In the remaining track of the intestine, the animalisation is rendered more complete: the chyle, gradually and progressively formed, is absorbed, carried into the blood, and then applied to supply the different organs, after having been more completely elaborated in the lungs. We must pursue this progress in the order.

It has been always, but with little accuracy, supposed that digestion takes place in the stomach. This is not true; for not a particle of chyle can be at any time discovered in its lymphatics, coloured matters do not tinge their contents; and what is called the chyme resembles in no respect the white fluid destined, at a future period, to fill the blood vessels. In the stomach then, perhaps, we shall find solution only in the saliva and other glands of that organ: but it is a solution which we may try in vain to imitate; because it takes place in an animated organ, whose power cannot be for a moment intermitted, without some injury to the result. Fermentation, also, probably soon comes on; and it is

apparently assisted by the gastric juice, which acts as a leaven, and in this way only. Such a process is peculiarly necessary in herbivorous and granivorous animals, since the change by solution alone is not sufficiently rapid for the wants of the system, or equal to the effect of breaking down the denser substances; and since, perhaps, one stage of assimilation may be necessary in this organ to prepare it for the second. If the gastric juice be formed, as Carminati suspects, and which is highly probable, since it differs in different animals, and always resembles the nature of their food, it is a ferment peculiarly adapted, not only to assist the separation of the parts, but, in some degree, to assimilate them to its own nature. The fluids of the stomach have no effect in dissolving the husks of vegetables, for instance; and consequently fermentation, in some cases, is absolutely necessary. So far, therefore, there is little mystery.

The distention of the stomach, after a full meal, is not, in the greatest degree, at its termination, if the appetite has not been stimulated by varieties, or by condiments. It is farther increased by the separation of air, which is sometimes so considerable as to rise to the cardia, and be discharged through the œsophagus. It is, however, generally again absorbed by the mass, and carried into the blood. The food detained in the stomach by the action of its longitudinal fibres is lessened in its bulk by the reunion of its air, and the absorption of its watery parts. The pylorus is then brought in a straighter line with the axis of the organ, and the fluid parts gradually pass over. It has been supposed that the pylorus possesses an elective power, to admit of the passage of some bodies, and to refuse others. In every part of the animal economy we seem to perceive a similar power; nor dare we deny it to an organ of so much importance, whose nerves are peculiarly and acutely sensible. Richerand, who has most pointedly enforced this opinion, seems to think that this elective power is at last lost. The stimulus which excited, by its disagreeable impression, the contraction of this aperture, becomes, in time, habitual, and the passage is effected. Independent, however, of this cause, heavy bodies not soluble in the watery fluids are not, for a long time, discharged. They lie at the bottom of the stomach; are not presented to the pylorus when it is full; and, when empty, they cannot rise to the angle which that passage forms. In this way, heavy metallic bodies, and even the heavy mucus of weak stomachs, are not discharged. The stimulus of the latter soon becomes habitual; but, after some time, the action of this organ seems to be excited, and the former are propelled into the duodenum.

The food then in the stomach is in part dissolved by the saliva and fluids of the organ; broken down by fermentation, and, by the latter process, in part animalised. In this state it is carried into the duodenum, a portion of the intestine, for the reasons assigned, capable of a considerable dilatation. It is here exposed to the influence of bile, a fluid, as we have seen, which has almost undergone a second circulation, without being exposed to the air; or, what is of more consequence, without being mixed with fresh animal matter. It is evidently more animalized than any other fluid of the body; and, by its union with the chyme, new combinations take place, which have not yet been accurately observed. Our food, we have said, consists of

gelatine, oil, and sugar. These substances are the chief component parts of the chyle. When the vegetable substances are then broken down, we want little more than their separation from the other ingredients, which may be probably effected by the bile, and perhaps the combination of a small portion of azote. Fourcroy supposes that the alkali, and other saline parts of the bile, are combined with the chyle to attenuate it, and that its resin is discharged with the excrements. We should rather suspect that the alkali itself was decomposed, and its azote only combined with the chyle. We certainly find the resin of the bile in the excrementitious part of the contents of the intestines. The pancreatic fluid is here also added; and we have reason to suppose that it dilutes the chyle, while, as an animal fluid, it contributes to the necessary change.

The next portion of the intestine is called *jejunum*. It is distinguished by no peculiar structure, and differs from the rest of the small intestines by being frequently found empty. The only consequence to be drawn from this is, that, in the duodenum, digestion is perfected, and no longer delay is required. As the food, however, proceeds, the process of animalisation appears to go on; and, from the large intestines, the chyle seems to differ in some respects, at least in colour, from that which is carried from the ilium.

In the progress of the alimentary fluid through the lacteals, we find it often conveyed into glands, called *lymphatic*, or *conglobate*. It is here apparently deposited into cells, and mixed still more intimately with animal fluids, from whence it is absorbed by other lacteals, which apparently possess some elective power. Partly for the purpose of a more complete animalisation, and partly to prevent any noxious substance from contaminating the vital fluid, these glands are seemingly interposed. We see an equal anxiety for each purpose in the further provisions. The new aliment is mixed in the thoracic duct with the lymph, absorbed from every cavity, and, even after every precaution, conveyed almost by drops into the blood. It is thus carried gradually to the heart and the lungs, where the last process takes place.

We are now well acquainted with the changes which are produced in this part of the animal system. Atmospheric air is absorbed, and its oxygen, in part, uniting with the blood, gives it a florid hue; and, in part, combining with the carbone, separates it in the form of carbonic acid gas. It is, indeed, doubtful whether any oxygen remains; and whether the separation of the carbone alone may not produce the sensible changes attributed to the oxygen. Our vegetable food, by the gradual admixture of fluids more highly animalised, has now become near to our own nature, but it is still not azotic. This last principle seems to be supplied by the air, from whence azote is very probably absorbed. The experiments by which this is ascertained are not before the public; but those communicated to us render it highly probable.

It may be said, that, though the bile be obstructed, digestion goes on. It does so; but imperfectly, and the body is emaciated, the strength diminished, and atrophy is the consequence. There is some doubt whether any considerable portion of nourishment is, in such cases, conveyed through the lacteals, and whether the body is not supported by absorption from the adipose membrane,

It will be obvious, however, that some nourishment must still be obtained; for the bile, returned to the blood, is discharged by every excretory duct, and, among the rest, by the mucous glands and the pancreas. A small portion, therefore, finds its way to the digestive organs; and those who have remarked with how inconsiderable a degree of nutriment the body is sometimes supported, will not be surprised at the effect of the pittance it must in this way receive.

Another objection will be suggested, by the almost total obstruction of the mesenteric glands in some cases of scrofula. Yet, on minute observation, it will appear that every lacteal does not press through a gland. Sometimes it creeps over the surface to immerse in the following; and sometimes it seems cautiously to avoid every body of this kind interposed.

The "play of affinities," which takes place on the mixture of the bile, is not yet understood. It is certainly considerable; for we sometimes find the benzoic acid in the excrements of herbivorous animals, and sometimes the phosphoric. The former we have reason to believe, from some late experiments, to be a product, whose basis is the vegetable acid; and the latter we have begun to detect in its disguise, and to trace its source in grain. These subjects will soon be more clearly elucidated. Whether produced in the intestines, in the different cavities, or in the circulating system, is yet uncertain; but the phosphoric acid and the ammonia are the creatures of the animal economy, produced by the new combinations constantly taking place.

The red globules of the blood, though evidently derived from the nutriment, resemble so little every part of it, except the oil, that we must profess ourselves ignorant of their source. They are not oily; and though we lose the oil that makes a part of our food, and which is discoverable in the chyle, we can scarcely think that it forms this singular portion of our fluids. It is apparently decomposed, and affords the hydrogen, which is a component part of the animal economy. When we reflect, however, on the other hand, that we have scarcely any instance of globules swimming, unmixed, in a watery fluid, without being oleaginous; that oil affords a very solid, substantial nutriment; and that the red globules are numerous and vivid, in proportion to the strength of the constitution; we have some reason to suppose that they derive, in part, their origin from this source, though changed in their chemical properties. The application of these newly formed fluids must be the subject of future consideration. See NUTRITION.

The digestibility of different substances we considered under the article ALIMENT, and we there spoke from observation, assuming, as the criterion, the exacerbation of hectic paroxysms, which always occurs during digestion, and is greater in proportion to the difficult solubility of the food. Constitutions, however, greatly differ in this respect; and we ought to add, that the opinions of other authors differ from our own. We shall, therefore, adduce the conclusions of a respectable observer, M. Gosse, of Geneva, who, by swallowing air, was at any time able to discharge the contents of the stomach. His experiments are recorded in Spallanzani's work; but, that we may not be suspected of distorting them to favour our own ideas, we shall transcribe the account from a late respectable, but unequal, publication.

"He informs us, that in about an hour and a half after the food is taken into the stomach, it is changed into a pultaceous mass; the gastric juice, likewise, renders it fluid, without altering its nature; and when digestion is properly carried on, there is no appearance of acidity or alkaliescence; the food does not ferment; and the process of digestion is not completed until the space of between two and three hours has elapsed.

"The chyme which arises from aliments taken either from the animal or vegetable kingdom is the same; they both are, by the gastric fluid, converted into the same substance, which is in consequence most probably of their both containing gelatine, &c. If, however, the digesting solvent is not in sufficient quantity, or is in a diseased state, the acetous fermentation will take place in vegetable, and the putrid in animal, matter; hence milk, vegetable matter containing sugar, wine, and even spirits, will degenerate, when left to their spontaneous changes in the stomach, to a very strong acid, and sooner sometimes than out of the body, perhaps from the heat, &c. All oily substances likewise become rancid, and flesh meat putrid, producing acid and putrid eructations, which is never the case in a state of healthy digestion; whilst, in many animals, the digestion is finished before the acetous or putrid fermentation can begin.

"Substances insoluble, or that were not digested in the usual time in the stomach.

"Animal substances.

"1. Tendinous parts. 2. Bones. 3. Oily or fatty parts. 4. Indurated white of egg.

"Vegetable substances.

"1. Oily or emulsive seeds. 2. Expressed oils of different nuts and kernels. 3. Dried grapes, and the skins of fish. 4. Rind of farinaceous substances. 5. Pods of beans and peas. 6. Skins of stone fruits. 7. Husks of fruits with grains or seeds. 8. Capsules of fruit with grains. 9. Ligneous stones of fruits. 10. It does not destroy the life of some seeds; hence bitter-sweet, hemp, misletoe, and other plants which sometimes grow upon trees, are produced by the means of the excrements of birds, the kernels of the seeds being defended from the menstruum by their exterior covering.

"Substances partly soluble, or parts of which were digested.

"Animal substances.

"1. Pork dressed various ways. 2. Black puddings. 3. Fritters of eggs, fried eggs and bacon.

"Vegetable substances.

"1. Salads of different kinds rendered more so when dressed. 2. White of cabbage, less soluble than red. 3. Beet, cardoons, onions, and leeks. 4. Roots of scurvy grass, red and yellow carrots, succory, are more insoluble in the form of salad than any other way. 5. The pulp of fruit with seeds, when not fluid. 6. Warm bread and sweet pastry, from their producing acidity. 7. Fresh and dry figs. By frying all the substances in butter or oil they become less soluble. If they are not dissolved in the stomach, they are, however, in the course of their passage through the intestines.

"Substances soluble, or easy of digestion, and which are reduced to a pulp in an hour, or an hour and a half.

"Animal substances.

"1. Veal, lamb, and, in general, the flesh of young

animals, are sooner dissolved than that of old. 2. Fresh eggs. 3. Cow's milk. 4. Perch boiled with a little salt and parsley. When fried or seasoned with oil, wine, and white sauce, it is not so soluble.

"Vegetable substances.

"1. Herbs, as spinach mixed with sorrel, are less soluble, celery, tops of asparagus, hops, and the ornithogalus of the Pyrenees. 2. Bottom of artichokes. 3. Boiled pulp of fruits, seasoned with sugar. 4. Pulp or meal of farinaceous seeds. 5. Different sorts of wheat bread, without butter, the second day after baking, the crust more so than the crumb. Salted bread of Geneva more so than that of Paris, without salt; brown bread in proportion as it contains more bran is less soluble. 6. Rapes, turnips, potatoes, parsnips, not too old. 7. Gum arabic, but its acid is soon felt. The Arabians use it as food.

"Substances which facilitated the menstrual power of the gastric juice are, sea salt, spices, mustard, scurvy grass, horse radish, radish, capers, wine, spirits in small quantities, cheese, particularly when old, sugar, various bitters.

"Substances which retarded the gastric power are, water, particularly hot, and taken in large quantities. It occasions the food to pass into the intestines without being properly dissolved. All acids, astringents, 24 grains of Peruvian bark, taken half an hour after dinner, stopped digestion. All unctuous substances, kermes, corrosive sublimate. Gosse likewise observed, that employment after a meal suspended or retarded digestion, as well as leaning with the breast against the table; and that repose of mind, vertical position, and gentle exercise, facilitated it."

See Fordyce on Digestion; Richerand's Elements of Physiology; Senchier's Observations (Journal de Physique, Mars, 1785); Carminiati's Experiments, *ibid.* vol. xxvi.; Spalanzani's Tracts; Brugnatelli Sagio d'un Analisi Chimica de succi Gastrici; Steven's Thesis; Gosse's Experiments.

DIGESTIVUM, SAL SYLVII, (from the same). See MARINUM SAL.

DIGESTIVA, (from *digero*, to dissolve). Such applications as promote suppuration, viz. ointments rendered stimulating by turpentine and balsams, poultices and fomentations. The object is to excite suppuration by stimulating the vessels, when too languid; to hasten it when the process goes on too slowly; and to relax the vessels when their action is sufficient. By these effects the choice is easily directed.

DIGITALIS, (from *digitus*, a finger). *Aralia, digitalis purpurea* Lin. Sp. Pl. 758. It is a hairy plant, with serrated leaves; a thick angular stalk, on which are numerous purple tubulous flowers, resembling the finger of a glove, hanging downwards, in a row along one side, each on a short pedicle; the flower is followed by an oblong pointed capsule, full of small angular seeds. It is biennial, grows wild in woods and on heaths, only in gravelly soils, and flowers in June, July, and August.

The leaves are bitterish and nauseous to the taste; they yield their virtue both to water and to spirit. Dr. Hulse recommends an ointment made by boiling it in butter, as an application to scrofulous ulcers, with gentle purging two or three times a week.

Dr. Withering considers this as one of the most cer-

tain diuretics in the whole materia medica. The leaves, which are chiefly employed, are given from one to three grains, in powder, twice a day, alone, or united with aromatics, and sometimes formed into pills with soap and gum ammoniac: the dose may be gradually increased; but four grains are generally sufficient in drop-sical cases. A drachm of the dried leaves may be infused in half a pint of boiling water, for four hours, adding to the strained liquor an ounce of any spirituous water: two table spoonfuls, or an ounce given twice a day, is a moderate dose for an adult: if the patient be stronger than usual, or the symptoms very urgent, this may be given once in eight hours; but, in many instances, half an ounce will be sufficient. When this medicine purges, it is said to fail of success, and opium may be advantageously joined with it: but when the bowels are too tardy, jalap may be added. It seldom succeeds in men of great natural strength, of a tense fibre, warm skin, florid complexion, and a hard pulse. But if the pulse be feeble, or intermitting, the countenance pale, the lips livid, the skin cold, the belly soft and fluctuating, the anasarcoous limbs readily pitting with pressure of the finger, we may expect the diuretic effects to follow in the most salutary manner. If given in the form of extract, it must be joined with exercise and tonics. The decoction is occasionally preferred to the powder, and given in the following form: R. Digitalis purpureæ recentis ℥iv. aquæ distillatæ ℥ij. coq ad ℥i. et liquor colato adjiciantur spt. vinosi ℥ij. fiat decoctio.—One large spoonful is to be administered every morning, in every variety of idiopathic dropsy, and repeated every hour, till the patient has taken from three to eight or nine spoonfuls, or till sickness, or some other disagreeable sensation, be induced. The hydropic fluid generally disappears on the next or on the third day, without any repetition of the medicine; and frequently without any apparently increased evacuation; at other times, with vomiting and a large flow of urine; and sometimes with purging stools.

Such is the flattering account of Dr. Withering; but we cannot confirm it from experience in every part. The digitalis is of a suspicious order, and its exhibition is attended often with inconvenience. Vertigo, sickness, and faintness, frequently follow. More than one patient has died suddenly during its exhibition; and, though these sudden terminations in dropsy are not uncommon, we have apprehended that this poisonous plant may have had a share in the event. We have, therefore, always prescribed it with a trembling caution, and have scarcely ventured giving above two grains three times a day. After some time the pulse becomes slower, the patient weaker, and it seems to be owing to the general relaxation which takes place that the urine passes off. It is singular, but undoubtedly true, that it should be useless in dropsies of the young and strong.

From its lowering the pulse, it has been given freely in spasmodic asthma, and hectic, so far as our experience goes, without success. The pulse is, indeed, rendered slow; but the other symptoms remain with little melioration.

The unguentum digitalis is made in the same manner, and applied to the same uses, as that of cicuta; the ingredients are equal parts of the digitalis purpurea, recently gathered, and hog's lard. (For the process, see

CICUTA.) It is also a name of the *sesamum orientale*. See SESAMUM VERUM.

DIGITA'LIS MINIMA. See GRATIOLA.

DIGITA'TUS, (from *digitus*, a finger). In botany it means divided into several parts, and meeting together at the tail; like a hand, and its fingers. It is applied to the leaves.

DIGI'TIUM, (from *digitus*, a finger). A contraction of the joint of a finger; and a pain, with wasting of the same part. See also PARONYCHIA.

DIGITO'RUM TE'NSOR. See EXTENSOR DIGITORUM COMMUNIS.

DIGITUS, (from *digero*, to direct, as the natural instrument of pointing or directing). A FINGER. In the hands they have particular names. The first, which is opposite to, and thicker than the rest, is called *ὑποχέρις*, and *pollex*; the second, *index*, *λίχανος*, and *salutaris*; the third, *μεσος*, *medius*, and *longissimus*; the fourth, *παραμεσος*, and *annularis*; and the fifth, *minimus*, *auricularis*. The Greeks called the thumb, *ὑποχέρις*, because it was alone as powerful as the other four fingers, from *ὑπὲρ*, against, and *χείρ*, the hand; and the Latins *pollex*, from *pollendo*, for the same reason. The second, or fore finger, *λίχανος*, *index*, because, by pointing, discoveries are made, or indications given; and *salutaris*, because, being applied to the mouth, it causes a salutary silence. The third, *μεσος*, *medius*, and *longissimus*, the middle finger, from its situation and length. The fourth, *παραμεσος*, because it was beyond the middle finger; and *annularis*, from wearing rings upon it, hence called ring finger. The fifth, *auricularis*, from its clearing the ear, and *minimus*, from its size. The toes have no names. The thumb and the four fingers are each composed of three bones; those of the fingers are formed alike, but those of the thumb are much thicker and stronger, in proportion to their length. On the outside, the bones of the fingers are convex, within flat. Both ends of the first phalanx are in a cartilaginous state at birth. The first joint of the fingers is arthrodia, the two last are ginglymus. The different parts or bones of the fingers are called *phalanges*; the first phalanx is the largest, and the last the least. (See PHALANX). *Digitus*, among the Latins, stands also for a measure, similar to *dactylus* among the Greeks; the smallest measure, by which the distances of space or time are measured, similar to our jot. However, at the present day, it seems to be a measure taken from the breadth of the finger, properly three fourths of an inch, and equivalent to four grains of barley laid breadthwise, so as to touch one another. Astronomers preserve the name in the division of a great circle, *digit*.

DIGLO'SSON, (from *dis*, *bis*, and *γλῶσσα*, a tongue). A name of the *laurus Alexandrina*, because that above its leaf a less leaf resembles a tongue.

DIGNO'TIO, (from *dignosco*, to distinguish.) See DIAGNOSIS.

DIGY'NIA, (from *dis*, *bis*, and *γυνή*, mulier.) The name of an order in Linnæus's artificial system, comprehending those plants which have two pistils.

DIHÆ'MATON, (from *δια*, and *αἷμα*, blood). The name of an antidote, in which is the blood of many different animals.

DIHA'LON, (from *δια*, and *ἅλς*, salt). A plaster prepared of salt and nitre, adapted to foul ulcers.

DII'PETES, (from *διος*, heaven, and *πιπῶ*, to fall; i. e. falling as rain). See SEMEN.

DILATA'TIO, (from *dilato*, to expand,) *distentio*; DILATATION. Sometimes it is used for *diastole*.

DILATATO'RES ALA'RUM NA'SI, (from the same). DILATORS OF THE NOSTRILS. They are small, thin muscles, having a double order of fibres decussating each other. They rise from the interior and inferior parts of the ossa narium, and are soon inserted into the superior parts of the alæ. They raise the alæ, and dilate the nostrils.

DILATATO'RIMUM, (from the same). A surgical instrument for dilating any part.

DILL. H. MUSC. An abbreviation of *Johannis Jacobi Dillenii Historia Muscorum*.

DILUEN'TIA, (from *diluo*, to wash away). DILUENTS. These are fluids, which render the substance with which they are mixed still more fluid, without adding any acrimony, and are almost universally water. Heat cannot be considered of this kind, because it is not, in the strict sense of the word, a fluid; and, when salt renders the serum more fluid, the term is improperly applied.

Diluents are, therefore, watery fluids alone; and these undoubtedly dilute the contents of the stomach and bowels; but, should lentor or vicidity exist in the blood, water alone will not remove it. If water is absorbed, it is soon again carried to the kidneys or the skin, and evacuated without any impregnation. Some diluent effect may be produced, if, by joining any of the farinacea, the watery fluid is subjected to the powers of digestion.

DILU'TUM, (from the same). DILUTED. See INFUSUM.

DILYTÆ'A. In Myrepsus, it is the fat of some unknown animal.

DIMIDIA'TUS, (from *dimidium*, half,) divided into half.

DI'NICA, (from *divew*, to turn round). Medicines against a vertigo.

DINNER, (from the barbarous Latin word *disnare*, to dine). The principal meal, which should be taken about the middle of the day. See DIÆTA.

DI'NOS, (from *divew*, to turn round). See VERTIGO.

DIO'BOGON. See SCRUPULUS.

DIO'CRES. The name of a pastil in Myrepsus.

DIO'DOS, (from *δια*, and *ὁδός*, the way through). See DIEXODOS.

DIO'CIA, (from *dis*, *bis*, and *οἶκος*, domus). A vegetable which has no hermaphrodite flower; but in which the male flower is upon one plant, and the female flower upon another. It is the twenty-second of Linnæus's classes.

DIËNA'NTHE'S, (from *δια*, and *οἶνον*, the flower of the vine,) an epithem in Trallian against the cholera morbus.

DIO'GMUS, (from *διωκω*, to persecute). See PALPITATIO CORDIS.

DIO'NIS COLLY'RIMUM. A collyrium in Oribasius, so called from Dion its author.

DIONY'SIA. The name of a plaster for abscesses, invented by Hera the Cappadocian; also called *dionysianum emplastrum*.

DIONY'SIAS, (from *Διονυσος* Bacchus, or wine). See ANDROSÆMUM.

**DIONISI'SCI.** HORNED. Certain bony eminences near the temples; or rather the race distinguished by those prominences; from Dionysius, a name of Bacchus, described as horned.

**DIONY'SIUS.** See **LEPIDIUM**.

**DIONY'SOS.** The name of a collyrium in Ætius; one resembling it is found in P. Ægineta, called *collyrium malabathrinum*, and *isotheon*.

**DIOPO'RON**, (from *δια*, and *οπωρα*, autumnal fruit). The name of a medicine in Cœl. Aurelianus, used against the quinsy.

**DIO'PTRA**, (from *διοπτομαι*, to see through). An instrument for dilating any natural cavity, the better to see its state, as the speculum uteri.

**DIOPTRICS**; glasses employed to view distant objects, where the rays pass through the lens, in opposition to those where the object is examined after reflection. Spectacles are dioptrical instruments.

**DIOPTRISMOS**, (from *διοπτομαι*, to see through). The operation which consists in dilating the natural passages with a dioptra.

**DIO'ROBON**, (from *δια*, and *ροβος*, a vetch). A medicine containing vetches.

**DIORRHOSIS**, or **DIORO'SIS**, (from *δια*, and *ορις*, serum,) a conversion of the humours into serum and water.

**DIORTHO'SIS**, (from *δια*, and *ορθος*, right, or from *διορθωω*, to direct). The restitution of a fractured limb to its natural situation.

**DIOSCO'R.** An abbreviation of Pedacii Dioscoridis Opera.

**DIOSCU'RI**, (from *Διος κουροι*, the sons of Jupiter, *Castor* and *Pollux*: the parotid glands are so named from their equality in shape and position). See **PAROTIDES**.

**DIO'TA**, (from *δισ*, double, and *οτος*, from *ους*, the ear). The name of a wooden cup, with two ears or handles, lined with aromatics, to give a flavour to the liquor contained in it.

**DIOXELÆ'UM**, (from *δια*, *οξυς*, acid, and *ελαιον*, oleum). A malagma of oil and vinegar.

**DIO'XUS**, (from *δια*, and *οξυς*, acid). The name of an acid collyrium in Marcellus Empiricus.

**DIOSPY'ROS.** See **GUAJACANA**.

**DIP'CADII.** See **BULBUS VOMITORII**.

**DIPCÆ'A.** See **CIRCÆA**.

**DIPETALUS**, (from *δισ*, double, and *πέταλον*, a petal). Consisting of two petals.

**DIPHRYGES**, or **DISPHRYGES**. **SCORLÆ**; (from *δισ*, twice, and *φρυγα*, to torrefy). There are three kinds; 1st, Metallic, produced only in Cyprus; found in the mud of a pool, whence it is taken and dried in the sun, then burnt; as it were twice roasted. 2d, The dross in working copper. 3d, Pyrites calcined to redness.

**DIPLOE**, from *διπλος*, double, called also *medistulium*. It is the soft part between the two tables of the bones of the skull.

**DIPLO'MA**, The written instrument which gives authority for physicians to practise. It is usually written on parchment, and folded up; hence its name, from *διπλωω*, to fold. Diplomas are now disgracefully sold by colleges founded for better purposes; and the blockhead, who cannot write a prescription, ranks with a man of the greatest learning and experience. Also a **DOUBLE VESSEL**. To boil in diplomate, is to set one

vessel, containing the ingredients intended to be acted upon, in another larger vessel full of water, and to this latter vessel the fire is applied. See **BALNEUM MARIÆ**.

**DIPLO'PIA**, (from *διπλον*, *duplus*, and *οψις*, *visus*). A depravity of sight, by which the same objects appear double. The symptom is almost always of short duration, and we bear it freely. So long as the object is not within the distance of distinct vision, two images opposite to one faramen, or aperture, having fallen upon the eye, are not united in the retina, but in distinct places; and, therefore, they have not the optic point as a centre: whence the image appears double. The optic portion is a circular point in the bottom of the eye, whose centre the optic axis occupies: but as often as we look at any object with both eyes, so often, unless there should be some defect in the organs, we turn the eyes, that each axis may concur in the same point of the object; and we learn by long habit, that a double image answers to one object, and consequently we judge that object single: but if a double image should fall upon the same eye, and not concur in the optic point, then the same object appears to be seen in two different places, and therefore double. It frequently arises from weakness, when we lose the power over the muscles of the eye, so as not to be able to direct them with accuracy. The diplopia, then, is the forerunner of death, or in fevers, of delirium. At times, the defect seems to be in the brain beyond the eye; and it has been sometimes an early symptom of hydrocephalus, or of an abscess in the basis of the brain near the thalami nervorum optico-rum. Dr. Cullen makes it a variety of the second species of pseudoblepsia, which he calls *mutans*, in which objects appear changed from what they really are: and the disease varies according to the variety of the remote cause, of which he enumerates, from Sauvages, ten species. See *Nosologia Methodica Sauvagesii*, et Culleni. Wallis's *Nosologia Methodica Oculorum*, with notes.

**DIPNO'OS**, (from *δισ*, *bis*, double, and *πνεω*, to breathe). An epithet of wounds which penetrate through some cavity, or quite through a part, or that have two orifices, admitting the air at both ends.

**DIP'SACON**, the **TEASLE**, (from *διψα*, thirst). So called from the concave situation of its leaves, which will hold water, by which the thirst of the traveller may be relieved. See **ASPALATHUS**.

**DIP'SACOS**, (from *διψα*, thirst). See **DIABETES**.

**DIP'AS.** **DRY EARTH**, (from the same). Also the name of a serpent, whose bite causes thirst. See **COBRA**.

**DIPSE'TICUS**, (from *διψαω*, to thirst). An epithet for food which causes thirst.

**DIPYRE'NON**, (from *δισ*, *bis*, double, and *πυρην*, a berry, or kernel,) the name of a probe, with two buttons on one end. It is mentioned by Cœlius Aurelianus.

**DIPYRITES**, or **DIPY'ROS**, (from *δισ*, twice, and *πυρ*, fire). **BREAD TWICE BAKED**. Hippocrates recommends it in dropsies.

**DIRADIA'TIO.** See **ACTINOBOLISMUS**.

**DIRE'CTOR**, (from *dirigo*, to direct). A grooved instrument for guiding an incision knife.

**DIRECTO'RES PENIS**, (from the same). See **ERECTORES PENIS**.

**DIRI'NGA.** A name, in the isle of Java, for the **SWEET-SCENTED FLAG**. See **CALAMUS AROMATICUS**.

DISCE'SSUS (from *discedo*, to depart). A chemical term, in French *depart*, or *linguist*, signifies, in general, any separation of two bodies before united: but it is particularly applied to the separation of gold from silver by the nitrous acid, where the silver is dissolved, but the gold left untouched.

DISCOIDES, (from *δισκος*, the quoit used in the Roman games, and *εἶδος*, a form). See CRYSTALLINA.

DISCRETA PURGATIVA, (from *discerno*, to separate). A purgative which evacuates a particular humour.

DISCRI'MEN, is a small roller about twelve feet long, and two fingers broad, rolled up with one head, and used after bleeding in the forehead, in the following manner: the bandage is held with the left thumb upon a compress, so that about a foot hangs below the forehead; then the roller is carried round the temples and occiput in the circular direction; after this, the part which hangs down is to be carried over the head to the occiput, and there, having rolled it several times about the head, it is to be secured. It is a term also applied to the diaphragm.

DISCIFORME, (from *δισκος*, a quoit, and *forma*, likeness). See PATELIA.

DISCUS, (from *δισσω*, to throw). A DISK, or QUOIT, thrown to a great distance at a mark. It was one of the gymnastic exercises. In botany, the whole surface of a leaf; disk, of a flower, is the central part in radiate compound flowers consisting generally of regular little corollæ or florets; the term is also applied to other aggregate flowers, when the florets, towards the middle, differ from those in the circumference.

DISCU'SSIO, (from *δίσ*, and *quatio*, to shake through). See PERSPIRATIO.

DISCUSORIA, DISCUTIENTIA, (from *discutio*, to discuss, or shake to pieces). DISCUTIENTS, by Dioscorides called also *diachytica*. They are such medicines as dissolve or dissipate a stagnating fluid without an external solution of continuity. In all bruises the fluids are stagnant. If there is no ecchymosis, the vessels are distended and thus weakened, and the principal means of relieving is by exciting their action. Simple friction will often succeed. Ardent spirits, camphor, volatile alkali, the light subtile spirit styled arquebuse, which is only a distillation of spirits from some warm plants, are very active discutients. They are, however, more effectual when united with a sedative, particularly with opium; and it may indeed be doubted whether ardent spirits do not, in part, owe their virtue to their narcotic powers. Relaxants, particularly warmth, and oils, are injurious, and induce suppuration. Cold adds greatly to the effect of discutients, and the most volatile are the most powerful.

DISEASE. See MORBUS.

DISLOCA'TIO, (from *dis*, ex, out of, and *locus*, a place). To put out of its place. See LUXATIO.

DISPENSARY, (from *dispendo*, to distribute, the shop in which medicines are prepared). It is also the appellation of a modern institution, in which the poor are supplied with medicines and advice. It is more advantageous than hospitals, as a greater number of patients are relieved at a less expense; and less useful, as the diet and other circumstances cannot be properly attended to. It is generally the arena, in which the young physician can display his importance, and acquire practical knowledge. Every hospital, however,

has its out patients, which are nearly on the same footing with the patients of a dispensary; and, if necessary, are often visited at their own houses.

DISPENSATO'RIMUM, (from *dispendo*, to distribute, or set in order). DISPENSATORY. A work treating of the composition of remedies; called also *antidotarium*. A dispensatory contains a select number of formulæ, established by the authority of the government of each country, that the medicines may be prepared in a manner, not only correct, but active and uniform. The publication of authorized regular dispensaries is not, however, of a very early date; but, from the time of the Arabians, different works of authority have been considered as the directors of apothecaries. About the middle of the fifteenth century, the standard volumes were a treatise of Avicenna, and another of Serapion on Simples, which still remain; the *Antidotarium of Mesue*; another of *Nicholas of Salerno*, a tract of *Simon Januensis de Synonymis*; and one of an Arabian author, containing the preparation of simples and chemical remedies, under the name of *Liber Servitoris*. About the end of the century, a collection was made from these authors by Nicholas Præpositus of Tours; but chiefly from Mesue and Nicholas of Salerno. This general dispensatory was followed by the *Thesaurus Armatoriorum*, the *Lumen Apothecariorum*, and the *Luminare Majus*, compilations from the same source.

Of these two luminaries of modern pharmacy, Mesue seems to have lived early in the eleventh century, certainly before its end; and Nicholas of Salerno followed him. Under this name, we have, however, three pharmaceutical works. The principal is styled Nicholas Magnus; from this there is an abridgment, or rather a contraction, styled Nicholas Parvus; but, in a subsequent era, another Nicholas called Myrepsus, sometimes Alexandrinus, appeared, whose work is the largest of the three. We have decided *ex cathedra* on many disputed points of chronology in this short history; but have followed the more probable accounts, though we have not room to assign our reasons.

All these works are, in many parts, confused and complicated. The ingredients of the compositions are numerous and contradictory, and of the greater number it is difficult to ascertain the design. Some remedy was introduced for every complaint, and it was, of course, supposed that the whole would be an universal medicine.

The first dispensatory published by authority was that of Valerius Cordus, in 1542, by the authority of the senate of Nuremberg. It is chiefly taken from the authors above mentioned, with the addition of some chemical remedies, particularly ether. The work itself, now before us, is not scarce; but it is particularly known from the comments and quotation of Hoffman. This work was followed by Wecker, whose *Antidotarium Speciale* appeared in 1561, a distinct work from the *Secreta* of the same author, and by Renodæus, who published his *Officina Pharmaceutica seu Antidotarium* at Paris, in 1608; but these were the works of individuals.

The next dispensatory by authority was the *Pharmacopœia Bergamensis*, 1581; and it was followed by the *Pharmacopœia Augustana*, which appeared at Ausburg, in 1601; and, with the notes of Zwelfer, at Rotterdam, in 1653. The former was the reputed parent of every other dispensatory; and it was succeeded by that of London, in 1618, and of Paris, in 1637. In each too

much was copied from Nicholas of Salerno; but they are, when we consider the period at which they appeared, respectable collections. It is too common to despise the ancients; but those who have looked into the Pharmacopœias subsequent to the periods of Nicholas, will find in them the germs of our most boasted formulæ, though overloaded and disguised by the number of ingredients. It would not be an uninteresting work to restore to each author his original idea. The Persian Pharmacopœia, published in the same century, at Paris, containing the Arabian formulæ, will complete this short view of ancient pharmacy.

There were, indeed, many other Dispensatories published in the same century, or even more early; but, in general, copies from those which preceded. We shall add the titles of the works which had the best pretensions to originality. Of these the first and principal is Florentinum Antidotarium, of which we know not the date; but the Latin translation by Clusius, now before us, was published at Antwerp, in 1561; Montagna's Antidotarium, at Venice, 1565; Fioraventi's Secreti Rationali intorno alla Medicina, &c. appeared at Venice in 1600; Poterius's Pharmacopœia Spagyrica, at Frankfort, 1698; Juncken's Corpus Pharmaceutico-Medicum, at Frankfort, in 1697; Lemcry's Pharmacopœe Universelle, in the following year; and Mynsicht's Armentarium Medico-Chymicum, in 1631. An early Pharmacopœia, by Bauderon, whose date we cannot at present ascertain, was republished, with remarks, at Lyons, in 1681, by F. Verny.

The Dispensatories in the eighteenth century were too numerous to be particularly mentioned. The "mere muster-roll of names" would fill our page, which may be better employed by a slight discriminated view of the merits of the more modern authorised collections.

Every country of Europe has now its own Pharmacopœia, established by authority. In the north, the Swedish, the Danish, and the Russian, Dispensatories are respectable and correct collections of well arranged formulæ. The Danish merits, on the whole, the preference; though the Swedish is more chemically correct. In our own country, the late edition of the London Pharmacopœia is elegantly, and on the whole accurately, chemical. Perhaps it is too concise; nor does it always furnish the formulæ which extensive practice demands. The first edition appeared in 1618; but we cannot find that it was republished till the year 1746, and again in 1788. The Edinburgh college published their first edition in 1722, and it has been followed by editions in 1736, 1747, 1756, 1775, 1792, and 1803. Their last edition is a very elegant and accurate work. The Dublin college has not published any dispensatory till within these few years, under the auspices of Mr. Kirwan: it is what may be expected from a learned body, in an enlightened age.

In Germany, the Wirtemburgh Dispensatory was for many years the standard of German pharmacy, and the best edition was that of 1771. It was afterwards republished, but without any change; and is still a necessary work for those who study the labours of the former German practitioners: it is particularly referred to in Murray's Apparatus Medicaminum. In the north of Germany it has been superseded by the Berlin Dispensatory, the last edition of which is one of the most

complete Pharmacopœias which we possess; and by the Brunswick Dispensatory of 1777, a very inferior work, abounding in all the useless exuberance of some ancient collections. On the west, in Holland, the Leyden and Amsterdam Dispensatories direct the practice; but neither has lately been revised.

In the south of Germany, the Fulda Dispensatory is highly esteemed. It is a work of value, and may be perused in every country with advantage. That of Vienna was first printed in 1729, and reprinted in 1765. It has escaped us if any other edition has appeared. Dispensatories have been published at Presburg and Cracow; but they were early works, and of little value.

In France, the first Dispensatory appeared in 1637; and we know of no edition since that of Boyer, in 1758. The Pharmacopœia of Lyons, by Vitet, appeared in 1778, and is a very respectable collection.

The Spanish and Italian Dispensatories are of too little real value to detain us; and we shall close this article with a short enumeration of the principal collections of formulæ not authorised by any government.

The first of these, besides Renodæus and some others formerly mentioned, was Schroeder's Pharmacopœia, in 4to., published at Leyden, in 1656; Triller's Dispensatorium Pharmaceuticum Universale, in two volumes, 4to., published at Frankfort, in 1764: the first volume of this work contains the materia medica. A superior collection, however, is the Dispensatorium Universale of Reuss, in two volumes, 8vo., published at Strasburg, in 1791; and Spielman's Pharmacopœia Generalis, published at the same place in 1783, is a work of value. In our own country, the Dispensatories of Quincy, of James, and Strother, merit our commendation. The first, improved by Lewis, is still a most valuable pharmaceutical work; but the last improved edition by Dr. Duncan, junior, comprehending the last London, Edinburgh and Dublin Pharmacopœias, greatly excels every other collection we have seen. It is full, correct, and satisfactory: with all the improvements of modern science, from the best sources, most skilfully condensed. We owe numerous obligations to it in the present work. If it wants any addition, it is of the formulæ from some of the best Pharmacopœias of the continent; and the addition of another volume, with these formulæ, has been recommended. At present the deficiency is best supplied by the improved editions of Lewis, or by an excellent work entitled "Thesaurus Medicaminum," attributed, with some reason, to Dr. R. Pearson. An excellent work by Plenck, entitled Pharmacopœia Chirurgica, and an admirable little manual under the same title in English, must conclude our list.

DISPERMATUS, (from *dis*, and *σπέρμα*, *semen*). Bearing two seeds.

DISRUPTIO, (from *disrumpio*, to break asunder,) a violent lacerated wound which penetrates the skin to the flesh.

DISSECTIO, (from *dis*, through, and *seco*, to cut). Dissection. The cutting up a body, with a view of examining the structure of the parts. See ANATOMY.

It is scarcely an object of a work of this kind to teach the minutiae of anatomy, or, of course, to enlarge on the methods by which it may be most satisfactorily learnt. We rather design this article as subservient to forensic medicine, which is an object of considerable importance, and, in general, too much neglected by authors and

professors. We shall add, however, a few observations on this subject, for the assistance of the younger practitioners; we trust not without their use.

At the conclusion of the article *CHIRURGIA* we spoke of the necessity of frequently using the knife to attain a dexterity in accommodating the hand to every little change of direction; and we would now extend the advice by recommending, as frequently as possible, the dissection of those who die of disease. In the theatres of anatomical investigation, some days have generally elapsed before the body can be obtained, and some further time is necessarily lost before all the cavities can be examined. Exudations, in consequence of this delay, often take place; the blood vessels, if distended, assume a livid hue, and give an unfaithful idea of the real appearance of the parts, so that the practitioner does not learn to distinguish disease when it really occurs. If the dissection of diseased bodies be often practised, some of the sound parts will show the young practitioner their natural appearance, and, in turn, he will see every part in its proper colours.

In such circumstances, his dexterity may be improved by the introduction of probes, bristles, or other instruments, into the different cavities. The probang and catheter he may thus be able to introduce more readily. He may learn to pass a tent to the upper part of the nose, by conveying a string through it to the back part of the fauces; an operation on which, in hæmorrhages of the nose, life may depend. In fact, the young surgeon should take advantage of every opportunity of increasing his readiness in executing every operation which he may be ever required to perform.

Another circumstance of no little importance is, that he will learn, in the subject recently dead, and not injured by hasty and rough conveyance, to see the situation of different viscera with respect to the external organs. He will find, for instance, that at the *scrobiculus cordis* many important parts meet; the stomach, the gall bladder, and the colon. Each may produce pains there; and it should be his object to discriminate those which are owing to diseases of the different organs. He will learn also from the diseased state, what deviations sometimes take place in these respects. The stomach will be dragged down by a disease of the epiploon; the abdomen filled by one of the ovarium, &c. Each dissection, by careful observation, will thus afford a lesson either of instruction or caution.

Dissection, when necessary to ascertain real diseases, or to detect crimes, should be conducted with the greatest care. In the first instance, the pains are often distant from the seat. We remember a case where pain was almost exclusively confined to the region of the navel; the disease was a *scirrhus pylorus*: another which the best surgeons pronounced to be a *scirrhus* prostate; it was a stone impacted in the pelvis of the kidney: of a child whose complaints were attributed to a diseased liver; it was a mesenteric obstruction. Instances of this kind, and many we might add, will inspire a cautious distrust, and the propriety of a doubtful opinion, when originally offered. Yet nothing is more common than to find the most positive decisions. At this moment we have cases pronounced to be a wasting of the liver; a dropsy of the womb; and a polypus of the uterus; the sources of which are either unknown or evidently mistaken. Should such bodies be ever

opened, the physician and his science will be disgraced, except by some frauds which, we fear, are too common. Deviations from the common structure have been made by art; and it is always easy to find, in any circumstances, what we wish.

When it is the object to detect crimes, dissection becomes an object of considerable importance. The life of an innocent person may be the sacrifice of ignorance, inattention, or presumption. The principal inconveniences we shall enumerate, as they occur in the greater cavities. In the head, the surgeon is often called on to decide on the cause of death. This may have occurred in a paroxysm of passion, and an accidental rencounter; and death may have arisen from apoplexy, or a blow. In each case, the vessels will be turgid, especially if intoxication, a frequent attendant, has concurred. In such circumstances, it is necessary to know that the vessels of the brain in a healthy state are usually very conspicuous. If no considerable external injury, no inflammation corresponding to the part where a slight or probable blow may have been afflicted, are observable, it may be concluded that the patient did not die from violence. Even general inflammation, though considerable, will scarcely justify the contrary opinion; nor an abscess, if at the basis of the skull, its most common seat, support a different conclusion. On the contrary, a trifling, and even an inconsiderable blow, either on the temple or on the upper orbit of the eye, where the bone is thin, may be fatal; and in such circumstances, the most minute examination of the brain and its bony envelope is essentially necessary. The point of a small sword against the upper part of the orbit has been fatal, by penetrating the brain, though the organ of vision has escaped.

In the chest, blows and wounds, though violent, will not always be fatal; but, in this part of the body, the effects are generally obvious, and no doubt occurs that merits any elucidation.

In the stomach, we are often left in uncertainty. Blows at the pit of the stomach have been sometimes fatal, without leaving any trace. The effect, on this organ, is similar to concussion on the brain. Inflammation seldom points out any evident cause; and death, without any alteration of the structure, ensues.

Greater are, however, the difficulties when poison is the suspected cause of death; and it is necessary that every practitioner should be acquainted with the internal appearances of this organ. Fortunately, the taste of the most dangerous poisons soon guards a person from any permanent injury; and, of others, the effects are strikingly obvious. The idea of Mr. Hunter, that the gastric juice dissolves after death the substance of the stomach, and occasions erosions in it, is found to have no foundation; and it is a proof, among a thousand others, how far a preconceived opinion influences the most accurate observers. Lead, copper, and arsenic, can be ascertained by their most appropriated tests (see *VENENUM*). The vegetable poisons are too nauseous to escape the organs of taste, and the animal influence other organs. On the intestines we see only the effects of stimulant poisons, of inflammation, and its consequences. Wounds and bruises offer no subject of remarks, as they are sufficiently obvious. Yet sometimes, in severe bruises, the effects, for instance, of military punishment, an abscess forms below, rather

than on the part affected, and is occasionally the cause of death.

In cases of death, in real or supposed puerperal cases, it is absolutely necessary to know the appearance of the organs in a state of health, and in the puerperal state. A woman sometimes dies apparently from poison, and the supposed inducement to this rash act is suspected pregnancy. The cause is, sometimes, with difficulty decided in the early months. If the period of menstruation is at hand, the uterus will assume the appearance of early impregnation, and we once saw it at a different period, though the hymen was entire. The appearance of an uterus, lately gravid, ought also to be known, as it may be sometimes necessary to determine whether a person, who has voluntarily terminated her existence, may have been lately delivered. For two months, at least, and very often much longer, the appearance of a corpus luteum in the ovarium is decisive.

In cases of puerperal fever, the subject has been greatly confined by those who have described the appearances on dissection, being imperfectly acquainted with those of the puerperal state. The natural fulness of the uterine vessels has been styled inflammation, and the coagulable lymph a purulent discharge.

In dropsy in tympanites, as well as in the puerperal state just described, the vessels are peculiarly full, and give the suspicion of previous inflammation where none has existed. Adhesions often take place in chronic cases, in the last moments, or soon after death, and excite an unfounded suspicion of an inflammatory disorder having preceded. In real inflammation of the peritonæum, it is thickened, pulpy, and opaque.

A neatness in opening a body and again sewing the wounds, can be judged of by every one. The body should not be too much exposed. In dissecting the head, the integuments should be cut across from ear to ear. They may then be replaced, without disfiguring the subject. To examine the thorax, the cartilages of the ribs should be divided on each side, after dissecting off the integuments and the muscles, near the sternum, which may be turned back; and from the scrobiculus cordis, an incision should be made to each ilium, to examine the state of the abdominal viscera. When these viscera are taken out, ligatures should be made on every canal, previous to dividing it. The parts should be carefully replaced, and the integuments sown with what is styled the flat stitch. See C. Bell's System of Dissection.

**DISSECTUS**, (from *disseco*, to cut asunder). In botany it means cut into small notches, fringed.

**DISSEPIMENTUM**, (from *dis*, and *sepio*, to inclose round). It is the thin septum which divides the several cells in the fruit of plants. See **CAPSULA**.

**DISSEPTUM**, (from the same). See **DIAPHRAGMA**.

**DISSOLVENTIA**, (from *dissolvo*, to melt). By Dioscorides called *diachytica*; medicines which dissolve concretions in the body, not only calculous ones, of which we have already spoken, but coagulated lymph, polypi, tubercles, &c. This ridiculous fancy is not yet forgotten. In chemistry, dissolvents are menstrua.

**DISSOLUTIO**, (from *dissolvo*, to loosen). Dissolution; *liothymia*, *syncope*, and *death*. Solution of continuity is distinguished by the same appellation, and thus is synonymous with *diulysis*.

**DISSOLUTUS MORBUS**, (from *dissolvo*). See **DYSENTERIA**.

**DISTA**, (from *dis*, double). See **DYOTA**.

**DISTENSIO**, (from *distendo*, to stretch out). **DISTENTION**; *dilatatio*, *handiculatio*, *convulsio*. Tension has, however, a different meaning, and we shall return to it under the article **FEMUS**.

**DISTICHA**, or **DISTICHIASIS**, (from *dis*, double, and *στιχς*, a row or order). See **DISTRICHIASIS**.

**DISTICHIUM**, (from the same,) a species of barley which hath only two rows of grains.

**DISTILLATIO**, (from *distillo*, to drop gradually). **DISTILLATION**; *alsacta*, *catastagnos*. Sometimes it signifies the same as *defluxio*, or *catarrhus*; so Shakspeare speaks of "distilling rheum."

In pharmacy it is the separation of the more volatile from the more solid parts of any substance by means of heat. The operation itself consists of the condensing and collecting the lighter parts of bodies, previously rarefied by heat, and thus separated from the less volatile. Re-distilling a fluid several times from fresh parcels of the same kind, is called *cohobatio*; but little advantage is derived from this practice. When distillation is repeated, in order to purify or separate the matter distilled from some parts of less value, it is called *rectification*. Distillation with an alembic or a common still is called *per ascensum*, because the vapours rise and are condensed in the upper part of the vessel; and in this way all distillations may be performed that require no greater heat than boiling water. When a greater heat is required, retorts may be used; and as from their shape the volatile parts can only escape through the side, it is called *per latus*. When the heat is applied above the bodies to be distilled, and the lighter parts forced downwards, it is called *per descensum*: this method is now never used in pharmacy, though occasionally in the arts. When the volatile parts, rarefied by distillation, are dry, the operation is called *sublimation*. When no more heat is applied than is necessary just to raise a vapour, which when condensed only falls in drops, it is called a *cold distillation*: roses and other substances valued only for their flavour, and which do not admit of drying, are advantageously distilled in this way; and the dry cake, left after distilling roses, is well adapted for making a decoction or syrup: in this kind of distillation, the subject should neither be bruised nor have any water added to it: they should be gathered with the morning dew upon them: and a retort placed in a sand bath, with a receiver, is the best apparatus. The worm still is more frequently used, and called the *hot still*, because the materials boil; it communicates with a leaden spiral tube (the worm), placed in a tub filled with cold water (the refrigeratory); in this worm the vapours are condensed, and run out in a small stream into whatever vessel is placed to receive it.

The end of distilling is the separation of volatile substances from those with which they were mixed; as in obtaining vinous spirits, essential oils, volatile spirits, &c. or for the more speedy or effectual combination of such bodies as require a boiling heat for their union.

As a great object in distillation is to apply no more heat than is necessary to accomplish our intention, retorts are sometimes used, and are placed on an open fire. They are placed also in sand or in water, that the

heat may be more certainly adjusted to the degree of volatility which the subject to be distilled possesses. In distilling water, the menstruum should be attended to, as well as the heat to be applied; for, as some essential oils require the full heat of boiling water, they cannot be raised by the use of spirits of wine: this happens in distilling oil of cinnamon, and some other ponderous oils.

Retorts are proper when the subject to be distilled would corrode the metal of a still, as in the preparing a mineral acid, or other corrosive matters. Earthen vessels are sometimes used, and, on some few occasions, iron ones. But these, and many other observations on this subject, are fully noticed under the articles where an attention to them may be required.

**DISTILLATIO PER DESCENSUM.** See DESCENSIO.

**DISTINCTUS**, (from *distinguo*, to set apart). In botany it means distant, and without any contact of parts.

**DISTORTIO**, (from *distorqueo*, to twist aside). It is applied to the eyes, when a person seems to turn them from the object he would look at, and is then called *squinting*. (See STRABISMUS.) It also signifies the bending of a bone preternaturally to one side. See Bell's Surgery, vol. vi. p. 281.

**DISTORTIO SPIÆ, vel VERTEBRARUM.** **DISTORTION OF THE SPINE.** In this disease, the spine becomes more or less curved, and the power of the lower limbs is usually lessened or destroyed. Mr. Pott calls it a kind of palsy in the lower limbs; in another place he speaks of it as a useless state of them. From his account of the disease, it hath a scrofulous origin; but as its most striking symptoms are from the caries, which takes place in the bodies of some of the vertebræ, may it not be properly termed the *strumous spinal caries*? Mr. Bell, in his Surgery, vol. vi. p. 294, calls it *distortion of the spine*.

In this disease, the lower limbs are gradually weakened, or their power is wholly lost. A curvature of the spine nearly about the middle of the lumbar vertebræ is observed, with a crackling sound on bending them. It is sometimes said to take place on the neck, and to be attended with the same effects on the upper extremities; but we recollect no well authenticated case of this kind.

To this distemper both sexes, and all ages, are equally liable; though the majority of these patients are infants or young children.

When the attack is made on an infant of only one or two years old, the true cause is rarely discovered until some time after the effect has taken place; the nurse or parents suppose that the child is weakly, or hath been hurt at its birth. When, on the attack, the patient hath been used to walk, the loss of the use of his legs is gradual, though not in general very slow. At first he shows signs of being soon tired; he is languid, listless, and unwilling to move much, or briskly; soon after he is observed frequently to trip, although there be no impediment in his way. When he attempts to move quickly, his legs involuntarily cross each other, and he is frequently thrown down suddenly, and upon endeavouring to stand still and erect, even for a few minutes, his knees give way, and bend forward. When the distemper is a little farther advanced, it will be found that he cannot, without much difficulty, direct either of

his feet precisely to any exact point; and very soon after, both thighs and legs lose their sensibility, and become gradually paralytic. When an adult is thus affected, the progress of the distemper is much the same, but more rapid. Arrived at this state, whatever be the age or sex of the patient, complaint is made of twitching and frequent pains in the thighs, particularly when in bed, and of uneasy sensation at the pit of the stomach, when he sits on a chair or a stool, his legs are almost always found across each other, and drawn up under the seat; the power of walking is soon afterwards lost.

The true curvature is usually from within outwards, sometimes on one side, and sometimes there is a counter curvature resembling an S. This curve of the spine varies in situation, extent, and degree, being either in the lower, or, more rarely, in the upper part of the loins; sometimes comprehending one vertebra only, sometimes two, three, or more; by which the curve becomes necessarily more extensive: but, whatever variety these circumstances may admit, the lower limbs most frequently feel the effect. The arms are said to be sometimes paralytic; and a few instances are said by Dr. Motherby to have occurred, in which both legs and arms were affected. The effect is also different in different subjects: some are rendered totally and absolutely incapable of walking very early, or soon after the appearance of the curvature; others can move with the help of crutches, or by grasping their thighs just above the knees with their hands: some can sit in an erect posture or in a chair without much fatigue; others are incapable of it for any time: some have such a degree of motion in their legs or thighs, as to enable them to turn and move for their own convenience in bed; others cannot move without assistance.

When a naturally weak infant is the subject, the curvature is in the vertebræ of the back: it is not unfrequently productive of additional deformity by gradually rendering the whole back what is vulgarly called *humped*; and by subsequent alterations, such persons are shortened in their stature, and debilitated in their constitution; but in all cases where this effect has been gradually produced, whatever alteration made in the disposition of the ribs and sternum may contribute to such deformity, it will always be found that the curvature of the spine appeared first, and was the chief complaint. Such curvatures, however, do not produce paralysis in either extremity. The reason is, that, in general, the angle is less acute, so that the nerves are not injured; but should any be compressed, their fibres in these central cavities are so much intermixed in plexuses and ganglia, that the parts are weakened only, and their functions impaired, not destroyed. The chief inconveniences arise from the subsequent contraction of the chest and abdomen.

The general health of the patient does not seem, at first, to be materially affected; but when the disease has continued some time, and the curvature is thereby increased, many inconveniences and complaints follow. When the incurvation is in the neck, and to a considerable degree, by affecting several vertebræ, the child finds it inconvenient and painful to support its head, and is always desirous of laying it on a table or pillow, to take off the weight.—When in the dorsal vertebræ, there are a difficulty of breathing, loss of appetite, indi-

gestion, dry cough, quick pulse, what is styled tightness at the stomach, obstinate constipations or purgings, involuntary flow of urine and fæces, with the addition of what are called nervous complaints.

An adult, in a case where no violence hath been committed or received, usually complains first of weakness in his back bone, accompanied with a heavy dull pain, and great lassitude: this is soon followed by an unusual sense of coldness in his thighs, independent of the weather or any obvious cause: his limbs are soon afterwards affected with an unusual sensibility, and frequently convulsed by slight spasms, particularly troublesome in the night. Soon after this, he not only becomes incapable of walking, but his power of retaining or discharging his urine or fæces is considerably impaired. The adult, as well as the child, complains constantly of a tightness and pain at his stomach, and he finds all the offices of his digestive and respiratory organs much impaired.

The loss of motion in the limbs, which generally accompanies a distorted spine, proceeds from this distortion. Until the curvature is discovered, the complaint is considered as nervous; but when the state of the vertebrae is known, it is attributed to some previous blow, fall, or other accident. In some few instances these may have produced the effect; but, in the majority, some predisposing cause, in which the very essence of the disease consists, may be found; and this is a distempered state, generally an inflammation of the ligaments and bones, where the curve soon after makes its appearance. This occasions the ill health of the patient, and in time the curvature. The helpless state of the limbs is the consequence only.

It has been supposed that there is a dislocation of the vertebrae; but the spine bends forward only because the diseased bones, intervening between the sound ones, are unable to bear the parts above. From every circumstance it is evident, that the complaint arises from a scrofulous indisposition affecting the parts that compose the spine, or those in its immediate vicinity: this morbid affection shows itself in a variety of forms; but they, in every instance, determine the true nature of the distemper. Sometimes the deformity of the spine occurs, without any apparent disease of the bones composing it; sometimes the deformity is attended with erosion, or caries of the body of one of the vertebrae; and the same bones are occasionally found to be carious, without any crookedness or alteration of figure. Strumous tubercles in the lungs, and a distempered state of some of the abdominal viscera, are often attendants of this complaint.

When these complaints are not attended with an alteration of the figure of the back bone, neither the real seat nor true nature of the distemper is pointed out by the general symptoms, and they are frequently unknown while the patient lives. When the ligaments and cartilages of the spine become the seat of the disorder, without any affection of the vertebrae, the whole spine, from the lowest vertebra of the neck downwards, gives way laterally, forming a great curve on one side, sometimes a more irregular figure, attended with many marks of ill health. The attack is occasionally on the bodies of some of the vertebrae; and ulceration, with erosion of the bones, is the consequence. This erosion of the bones often produces the curvature peculiar to the disease, by wasting the body of each vertebra

affected; and then the spinal processes of the diseased vertebrae protuberate behind, in consequence of the decay of their fore parts. When the dorsal vertebrae are attacked, the sternum and ribs, for want of proper support, necessarily give way, and additional deformity is produced. It sometimes happens that internal abscesses and collections of matter are formed near the spine, which, affecting the spine with caries, and proceeding outward, produce what is called a psoas abscess, and destroy the patient.

If we carefully examine this disease, it will be found, as we have said, to originate from a scrofulous habit, perhaps from a disease of the ligaments, and particularly inflammation of the vertebrae themselves. What we style inflammation of the bones, differs from that of the softer parts. It is rather a slight increased action of the vessels, soon destroying their vital principle, probably from pressure, as distention is not admissible. The bones, thus partially destroyed, are pressed on unequally, and deformity necessarily ensues. When the outside of the vertebra is decayed, there is little change; for the flexors of the trunk are strong, and a slight stooping soon relieves the diseased part. When decayed within, to preserve the equilibrium, the neighbouring vertebrae start out. When the disease is on either side, the curvature is on the opposite, but the curvature on the side is seldom alone. To prevent uneasiness, the patient reclines to the opposite side, and this produces the counter curvature, formerly described.

It will be obvious that the nerves coming from the diseased bone will be compressed by the curvature; but this compression is not complete, and, like all imperfect compressions, is attended with irritation. Thus the early compression in hydrocephalus appears with all the marks of irritation. This is the reason why the paralysis, from curved spine, is attended with spasms, and differs, as we shall soon mention, in this essential circumstance, from other paralysees.

There is another circumstance of some importance, which we must add. If from tonics, or any general plan of restoring strength, the general health is amended, whatever remedy is directed to the spine, the disease is relieved, and often when no application is made. This, though not an isolated fact in nervous compressions, is yet difficult of explanation. It may arise from anastomosis of nerves; but we know not that nervous influence is retrograde or lateral. We suspect, therefore, that the nervous energy, like the arterial, is increased when any obstacle has been interposed; and by this increase the functions are, at least in some degree, restored.

Mr. Pott observes, that, in compliance with custom, he hath called this disease a palsy; but that, notwithstanding the limbs be rendered almost totally useless, yet there are some essential circumstances in which this affection differs from a nervous palsy: the legs and thighs are rendered unfit for all the purposes of loco-motion, and have lost much of their natural sensibility; but they have not the flabby feel of a truly paralytic limb, that seeming looseness at the joints, nor that total incapacity of resistance which admits of motion in almost all directions: on the contrary, the joints have frequently a considerable degree of stiffness, particularly the ankles, so that the feet of children are generally pointed downwards; and they are prevented from setting them flat

on the ground: the legs of the patient are either constantly kept stretched out, and considerable force is required to bend the knees, or they are by the action of the stronger muscles drawn across each other, and require as much to separate them. When the leg is in a straight position, the extensor muscles act so powerfully as to require a considerable degree of force to bend the joints of the knees; and when they have been bent, the legs are immediately and strongly drawn up, with the heels towards the buttocks; by the rigidity of the ankle bones, added to the spasmodic action of the gastrocnemii muscles, the patient's toes are pointed, as we have said, downwards in such a manner as to render it impossible for him to put his feet flat on the ground; which makes one of the decisive characters of this distemper. Thus the marks of distinction between this disease and the palsy are sufficiently strong to show the impropriety of confounding them, and from the slightest assistance the two diseases may be easily distinguished.

The restoration of the spine to its natural figure depends much on the early administration of the help proposed: though the distemper may be so far cured, as the patient may recover the use of his limbs, yet it is seldom possible to correct the curvature of the spine; and if the bodies of the vertebræ become completely carious, and the intervening cartilages are destroyed, no assistance is to be expected from any remedies. After the discharge produced by art for the removal of this disorder hath continued for some time, the patient begins to feel better health, he gradually recovers his appetite, is refreshed by his sleep, hath a more quiet and less hectic pulse; but the chief relief is from the loss of the distressing tightness about the stomach: in a little time a warmth and sensibility are felt in the thighs, to which the patient hath been long a stranger; and nearly about the same time the power of retaining and discharging the urine and fæces begins to be in some degree exerted. The first return of the power of motion in the limbs is rather disagreeable, as it is involuntary and spasmodic, principally in the night, and generally attended with sense of pain in all the muscles exerted. At this point it is not uncommon for the patient to remain for some time without making farther progress: this in adults occasions impatience, and in parents despair; but in the milder cases, the power of voluntary motion generally soon follows the involuntary. The knees and ankles by degrees lose their stiffness, and the patient can set his feet flat upon the ground—a certain mark that the power of walking will soon follow. The joints, no longer rigid, are weak; and the first voluntary motions are liable to great variation, from a number of accidental circumstances, both external and internal. The first attempts to walk are feeble, irregular, and unsteady, and bear every mark of nervous and muscular debility; but from this point no instance hath occurred in which the full power of walking was not soon attained. When the patient can first walk, either with crutches or between two supporters, he is generally unable to resist or overcome the more powerful action of the stronger muscles of the thighs over the weaker, by which his legs are frequently brought involuntarily across each other, and he is suddenly thrown down. Adults find assistance in crutches, by laying hold of the chairs or tables; but for children a go-cart is

the best assistant: it should reach up to the arm pit, and enclose the whole body. This takes off all inconvenient weight from the legs; and, at the same time, enables the child to move them as much as it pleases. Or the instrument of Mr. Jones should be worn, which, in all cases, would be serviceable, and in many a perfect cure, as it acts by taking off the superincumbent weight from the diseased vertebræ. See his Essay on Crookedness.

While the curvature of the spine remains undiscovered or unattended to, the case is generally supposed to be nervous; and nervous medicines are as generally administered, without advantage. When the case is known, recourse is too frequently had to steel stays, swings, screw chairs, &c. to restore the spine to its natural figure; but still the patient grows unhealthy, and, languishing under a variety of complaints, dies in an exhausted, emaciated state.

The remedy for this dreadful disease consists merely in procuring a large discharge of matter by suppuration, from underneath the membrana adiposa on each side of the curvature, and in maintaining such discharge until the patient shall have perfectly recovered the use of his legs. The effect of drains in all inflammations is well established; and it matters not by what means the discharge is procured, provided it be large, and from a sufficient depth.

In general, an eschar is made on each side of the curved part of the spine with a caustic: it should be of an oval shape, about an inch and a quarter in length, and three quarters of an inch in breadth, at the broadest part. Apply each caustic near the side of the curvature, so as to leave the portion of the skin covering the spinal processes of the protruded bones unhurt, and so large that the sores upon the separation of the eschars may easily hold, each, three or four peas in the case of the smallest curvature, but in large curves at least as many more. A few days after applying the caustics, the sloughs begin to loosen: it is then proper to cut out all the middle, and put into each a large kidney bean: when the bottoms of the sores are become clean in suppuration, sprinkle now and then a small quantity of finely powdered cantharides on them, by which they are prevented from contracting, and the discharge is increased. The issues should be kept open until the cure is complete; that is, until the patient has not only the perfect use of the limbs, but also his former good health. By means of this discharge, the inflammation is checked, and the cartilages between the bodies of the vertebræ having been previously destroyed, the bones are united with each other. No degree of benefit, nor any tendency towards a cure, is to be expected until the caries be stopped: the larger the quantity of bones diseased, and the greater the degree of waste committed by the caries, the greater must be the length of time required for its correction, and for restoring to a sound state so large a quantity of diseased parts. Nothing can be more uncertain than the time required to accomplish a cure: sometimes it is perfected in two months, and at others it requires two years; in the last circumstances, two thirds of the time have passed without any sensible amendment.

The discharge by means of the issues is principally requisite for the cure; yet every assisting means should be applied at the same time, in order to expedite it, such as the bark, cold bathing, frictions, &c. Yet, as we have already observed, general tonics and sea bathing

have at times effected the cure without the issues; and in that ease, nature, unassisted, restores the use of the limbs.

In the course of lecturing, in the year 1781, Mr. Pott observed, that it seems to be one of the few things that we may reason upon *a priori*, viz. that the whole train of the various symptoms of this disease are derived originally from a constitutional predisposing cause; for, whenever, in a curvature of the spine, the discharge begins to have any effect, the lesser symptoms, if they may be so called, as pain in the stomach, tightness across the breast, incapacity of holding the urine or fæces, all give way, before the removal of the lameness from the curve begins to take place.

It is to be observed, a curvature of the spine may take place from the *mollities ossium*, the rickets, and from other causes of caries. An aneurism often produces a caries in the bones; so an aneurism near a vertebra may render it carious: the venereal disease sometimes attacks the vertebrae, and produces the same effect. The scrofula is said to be the constant cause of the angular protuberance, attended with a useless state of one or more of the extremities: but may not any cause, that produces a caries in the vertebrae, occasion the angular instead of the curved appearance of the spine? and when the carious vertebra happens, so as that it is nearly destroyed, may not all the same symptoms proceed from its destruction, though the causes of the caries were various?

See Pott's Works on this subject; Jones's Essay on Crookedness; Select Cases of the Disorder commonly called the Paralysis of the Lower Extremities, by John Jebb, M. D. edit. 2; Bell's Surgery; Lond. Med. Journal, vol. vi. p. 358; Earle on the Distorted Spine.

**DISTORTOR O'RIS MUSCULUS**, (from *distorqueo*, to *wrest aside*). See **ZYGOMATICUS MINOR MUSCULUS**.

**DISTRA'CTIO**, (from *distraho*, to *draw apart*). In chemistry it is a forcible division of substances before united, either by separation or calcination.

**DISTRIBU'TIO**, (from *distribuo*, to *divide*). **DISTRIBUTION**. It sometimes implies separation. In medicine it relates to the nutritious juices, and is the same as *anadosis*, the distribution of aliment over the body; or to the excrements, and is then the same as *diachoresis*, or *diachorema*.

**DISTRICHI'ASIS**, (from *dis*, double, and *τριξ*, a hair). *Distichia*, *distichiasis*. A disease of the eyelid, which consists in its having a double row of hairs, or at the least supernumerary ones. Galen, and Ætius. See **TRICHIASIS**.

**DI'STRIX**, (from the same). The hair growing smaller and smaller.

**DIURE'SIS**, (from *δια*, by, and *ουρον*, urine,) the excretion of urine. It also signifies a **DIABETES**.

**DIURE'TICA**. **DIURETICS**, (from *δια*, by, and *ουρον*, urine). Medicines which are suited to promote the secretion and provoke the discharge of urine, either by increasing the quantity of water in the mass of blood, or by introducing a matter that may stimulate the kidneys. When medicines are designed to pass off by urine, walking gently in a cool air will assist their action; but considerable warmth directs them to the skin, or at least restrains their efficacy.

The object of this discharge is to carry off various sub-

stances, either injurious or no longer useful to the constitution. The principal of this is the urea, or, as it is sometimes called, the *uric acid*. With this we find muriat of potash and soda, phosphat of soda, lime and ammonia, with an excess of phosphoric acid, and an animal extractive matter. The greater number of these are the products of the animal economy, and they are thrown out as injurious. The animal matter has been styled *effete*, a word of no very distinct meaning; but, from the symptoms of disease, it appears to be that matter which is no longer adapted for the different functions of the organ of which it makes a part, but is absorbed and evacuated as excrementitious. See **URINE**.

The importance of this discharge is sufficiently obvious from the facts before us; and, when retained, the most violent symptoms follow. To obviate these, it is often necessary to restore it; and diuretics are medicines by which this object is effected.

From this view it appears that the mere evacuation of a watery liquid is not sufficient. In many fevers the water is sufficiently copious; but we find no portion of the necessary contents, and some febrile complaints are apparently kept up by their retention. We can often procure a mere watery discharge by frequent draughts of fluid; but it is frequently returned as pure as it is drunk; and, in dropsy, where we want only the discharge of fluid, we gain little, if only what we pour in is thus returned.

One singularity respecting this discharge has occasioned considerable surprise; we mean the very short time sometimes required for the evacuation of watery drinks, and the little impregnation which they receive. It has led to a suspicion that some ducts lead immediately to the kidneys from the stomach: but they have been sought for in vain; and, when we reflect on different facts respecting the secretions, we shall be led to suspect that it is not the same fluid which is evacuated, but that, when a supply is at hand, nature discharges a portion of fluid to prepare for its reception. Thus, at the sight of tempting food, the secretion of the saliva, and probably of the secretions of the stomach, are increased; and, in the opposite case, when the child is put to the breast, the sense of thirst is immediately felt.

Watery liquids alone will not excite, in any effectual degree, the action of the kidneys; but, if impregnated with the farinacea, or sometimes only with our indigenous aromatics, so as to become subject to the digestive power, they will succeed. In general, diuretics are to be divided into *cooling*, *sedative*, and *stimulant*. The cooling diuretics are the alkalis, chiefly carbonated, or supercarbonated; for the diuretic power of the pure alkalis is doubtful, except in the form of soap. The carbonic acid, when combined with alkalis in various mineral waters, and sometimes alone in water, is equally effectual; and all the neutrals, with either the fixed or the volatile alkali, occasionally act in the same way: the most powerful of the latter is the acetated ammonia.

Vegetable acids, either native or the product of fermentation, are considered as diuretics, and belong to the first order. All the vegetable fruits, particularly of the sentieosæ, and all the oleraceous plants, are of a similar nature, though weak in their powers. To assist their action the skin must be kept cool, and every stimulus

avoided; indeed, cold alone, or by means of water, applied to the skin, has a similar effect.

The *sedative* diuretics are more numerous than authors have supposed. The foxglove is at the head of the list; and the squill, though referable to the following order, seems to owe, in part, its virtue to its sedative power. The tobacco, the wild lettuce, the broom, the ice plant, the winter cherry (*physalis alkekengi*), the wolf's bane root (*doronicum pardalianches*), opium, which sometimes acts powerfully in this way, the woody nightshade (*solanum dulcamara*), the rue and savine, if diuretic, with some others, are of this class. They act, as already explained, under the article *CATHARTICS*, by the general relaxation they produce as deleterious substances. They are of doubtful efficacy, and should be always used with caution. See *DIGITALIS*.

The *stimulating* diuretics are chiefly vegetable. We borrow one only from the mineral kingdom, though of doubtful origin and efficacy, viz. the naphtha; and two from the chemists, nitrous ether, and oil of wine. Various are the plants arranged among the diuretics of this nature in the authors on the materia medica. Many of the umbellatæ; the most effectual of which are species of apium and daucus (parsley and wild carrot roots and seeds); the stellatæ; the asparagus, bardana, and seneca; the siliquosæ, the alliaceæ, coniferæ, and liliaceæ: of the siliquosæ, the *crysimum* is most effectual; of the alliaceæ, the allium and squill; of the coniferæ, the juniper; of the liliaceæ of Murray, the colchicum.

The balsams and resins merit our notice also in this place. The former may derive, in part, their virtue from the benzoic (perhaps the vegetable) acid; but there is reason to think that the oil contributes to the effect. The various turpentine is perhaps the most powerful. The Canada balsam is from a species of pinus, and the Chio turpentine from a similar vegetable, the pistaceæ terebinthus. The balsam copaiba, the gum guaiacum, the balsam of Peru, and the gum benjamin, follow in their order; though, as we advance in the list, the powers are weaker, and almost disappear. From some analogy, either botanical or therapeutical, the warm antispasmodic gums have been occasionally added to the diuretics. They may have some effect when the discharge is occasionally checked by spasm; but the olibanum, from a species of juniperus, and the styrax, from other analogies, have the fairest claim to our regard as diuretics. Mercury, which is so generally a stimulant, and sometimes acts on all the variety of glands, is occasionally directed to the kidneys.

The more immediate action of diuretics is connected with the general doctrines of secretion. It is sufficient to remark at present, that the greater number, by their chemical affinity, are confined to that portion of blood from which the urine is derived, the serosity. The stimulant diuretics are said to possess what is styled a specific power on the kidneys. This we must sometimes admit, when a better reason cannot be assigned; but, in this class, the stimulus is by no means confined. Many of the diuretics, by proper management, are sudorific, which may be, in part, explained from their chemical affinity; but they are also expectorant, and occasionally cathartic. In fact, the union of a vegetable acid with a warm oil, which constitutes the balsams and the turpentine, obeys the chemical affinity of either, according to the state of the constitution, or accidental

circumstances. Of the action of the sedative order we have already spoken.

Of the use of diuretics in fevers we are not prepared to speak. If the contents of the urine are retained, it will appear, at first sight, an obvious measure to restore the action of the kidneys by diuretics; but the attempt would fail. When the fever relaxes the obstruction, the proper discharge returns; but the cure of fevers is one of the arcana which we cannot yet fathom. It is sufficient if we can assist nature, and conduct them safely to their termination.

The abuse of diuretics, particularly of mineral waters, has been much insisted on. In fact, the long continuance of these medicines, when they produce the discharge, greatly relax the urinary and adjacent organs, and occasion a variety of distressing complaints.

See Hoffman's *Med. Rad. Syst.* Alexander's *Exper. Essays*, p. 149, &c.

**DIURETICUS SAL.** *DIURETIC SALT*; *acetated kali, sal Sennerti, tartarus regeneratus, and arcanum tartari; terra foliata tartari; essentielle sal.* It is a fixed vegetable alkaline salt, saturated with the acetous acid, and evaporated to dryness: when the process is carried no further, it is of a brownish colour, somewhat oily, and is called *tartarum regeneratum*. When purified to perfect whiteness, it is *sal diureticus*.

*Acetated kali* is prepared by boiling one pound of kali with four or five pints of distilled vinegar over a gentle fire: when the fermentation ceases, more distilled vinegar must be added, and when the fermentation subsides, still more. When the vinegar is nearly all evaporated, fresh vinegar will not excite any fermentation, which usually happens when about ten quarts have been used: then gently evaporate to dryness. The impure salt is to be melted for a time with a gentle heat, dissolved in water, and filtered through paper. If the melting hath been duly performed, the filtered liquor will be colourless: if otherwise, of a brown colour. The water is then to be evaporated with a very gentle heat, in a shallow glass vessel; the salt, as it dries, being frequently stirred, that the humidity may the sooner and more completely be discharged. It should be kept in a vessel close stopped, or it will dissolve by the moisture of the air. If, on dissolving a little of it in water, or the spirit of wine, any fæces are observed in either of these liquids, the whole must be dissolved in spirit, filtered, and again evaporated. *Pharmac. Lond.* 1788.

To succeed completely, the salt must be perfectly saturated with the acid, properly calcined, and at last dried, without too much heat. The first is ascertained by dipping a coloured paper into it, as directed in the article *SPT. MINDER*. The degree of calcination may be judged of, by dropping a little in water, and observing when it begins to part with its blackness readily: if, after this, the calcination is continued, the salt will be brownish. In the last drying, care must be taken not to melt it; for thus its whiteness will be lessened, in consequence of a decomposition of a portion of the acetous acid, and a deposition will take place on dissolving it in spirit, as the carbonate of potash is insoluble in alcohol.

The only use of rendering this salt white by depriving it of its oil, or carbone—for it is uncertain to what the colour may be owing—is, that it may rest more easily on weak stomachs; but if the process was carried on no

further than to saturate the alkaline salt, if the evaporation of the liquor was performed in a water bath, the oily part of the salt would not have an empyreumatic flavour, so as to become offensive; the remaining trouble would be spared, and a medicine of equal goodness obtained.

Dr. Lewis directs the salt of tar to be dissolved in cold water, and filtered, and then this solution to be saturated with distilled vinegar: after which the evaporation is to take place over a very gentle fire, so that the liquor may not boil, until a pellicle appears on its surface: the process must be finished in a water bath; the pellicle, as it whitens, must be taken off, and the fluid continually stirred, until the whole is taken away in the form of a white scum, which may be dried in an oven.

In making this salt, care should be taken to use a pure alkali, in which no neutral is mixed; but, in general, a mixture of the salt of tartar with vinegar, to a point of saturation, without evaporation, or any other trouble, is very little, if at all, inferior. Two drachms of the alkali saturated with vinegar, it is said, have been very successful in dropsies.

Some chemists have proposed making this salt by a decomposition of acetite of lead by carbonate or sulphate of potash. It may be very readily prepared by using the acetous acid separated from an acetated kali, made with common vinegar, by means of sulphuric acid.

In doses of about twenty or thirty grains, this salt is a mild, cooling aperient and diuretic; from a drachm to half an ounce it is purgative. As a purgative it is mild and easy, and as it is diuretic also, it is a peculiarly proper purgative in dropsies. In the jaundice and similar complaints this salt may be given to advantage, and preparations of steel afterwards employed. See Lewis's Mat. Med. Neumann's Chem. Works.

DIU'RNUS, (from *dies*, a day). An epithet of diseases whose exacerbations are in the day time.

DIUTU'RNUS, (from *diu*, a long time). Applied to diseases it signifies chronic.

DIVARICA'TUS, (from *divarico*, to spread asunder). In botany it means the branches spread wide asunder.

DIVARICA'TION, in medicine, signifies often the intersection of muscular or tendinous fibres.

DIVERGENS, (from *divergo*, to separate,) branches proceeding horizontally from the stem.

DIVERSO'RIMUM, (from *diverso*, to resort to). See RECEPTACULUM CHYLI.

DIVERTI'CULUM. A DEVIATION, chiefly applied to an unusual course of the intestine. Nuck applied this term to the opening through which the round ligaments of the uterus pass.

DIVI'NUM O'LEUM. See LATERITIUM OLEUM.

DIVI'NUS; appertaining to, or coming from, God. A pompous epithet of many compositions, from their supposed excellencies.

DIVI'NUS LA'PIS. The name of a preparation made by fusing alum, saltpetre, and Cyprian vitriol together, adding a small portion of camphor, while fluid.

DIVI'SUS, (from *divido*, to divide). In botany it means divided, separated into two parts.

DIVU'LSIO URI'NÆ, (from *divello*, to pull asunder). An irregular separation of urine, in which the sediment is divided, ragged, and uneven.

VOL. I.

DO'CHME. A measure among the Greeks of four fingers' breadth.

DOCIMA'STICA. See CUPELLA.

DOCIMA'STICE. The docimastic art: the art of analysing fossils.

DOCK. A common plant, of which different kinds are used in medicine, particularly the water dock, HYDROLAPATHUM, q. v. The wood sorrel is sometimes called the *sour dock*. The docks are, in their botanical analogy, nearly allied to the rhubarb.

DOCTILE'TUS. Paracelsus mentions it as a medicine for cancer; but he does not explain what it is.

DO'CTOR, (from *doceo*, to teach). The highest step in medical rank: formerly confined to men who were appointed by authority to direct the application of medicines for the prevention and cure of diseases. At this time the term is most shamefully prostituted; for, so far from being confined to men who have had the honour conferred upon them from merit, and a proper education, it is as liberally bestowed upon the most ignorant pretenders.

DOD. An abbreviation of Remberti Dodonæi Stirpium Historiæ Pemptades sex.

DODECADA'CTYLON, (from *δωδεκα*, twelve, and *δακτυλος*, finger's length). See DUODENUM.

DODECA'NDRIA, (from *δωδεκα*, twelve, and *ανηρ*, husband). The eleventh of Linnæus's classes of plants. It comprehends those plants which produce hermaphrodite flowers, and have from twelve to nineteen stamina. The five orders are taken from the number of the pistils.

DODECAPHA'RMACUM, (from *δωδεκα*, twelve, and *φαρμακον*, a medicine). See APOSTOLORUM UNGUENTUM.

DOCECA'THEON, (from *δωδεκα*, and *τιθημι*, pono). The name of an antidote which consists of twelve simples, described by P. Ægineta; and of the SANICULA.

DO'DRA. A potion among the ancients, consisting of nine ingredients.

DO'DRANS, (see CYATHUS,) the name also of a measure of nine inches, and a weight of ten ounces.

DOE'DYX, (from *δοιδυξ*, a pestle and mortar.) See COCHLEARIA.

DO'GGA. An Arabic term for the *paronychia*.

DOG AND DUCK WATERS. This spring is situated in Surrey, about half a mile from Westminster bridge. Its solid contents appear different at different times. Dr. Hales obtained from one gallon 324 grains; Dr. Fothergill, 200; Dr. Ratty, only 96. Of this about  $\frac{1}{12}$ th part is an earth, which, Dr. Ratty says, is soluble in acids, but does not calcine to lime: the salt is vitriolated magnesia and sea salt mixed together. Drunk from one to three pints, it generally purges briskly. See AQUÆ CATHARTICÆ AMARÆ.

DO'GMA, (from *δοκειν*, to be of opinion). It is a principle, tenet, or settled opinion, with regard to matters of faith or philosophy: in medicine, a sentiment founded on established principles, whatever may have been their basis. Hence,

DOGMA'TICUS. DOGMATIST. A sect of ancient physicians, of which Hippocrates is supposed to have been the first. They supposed principles drew conclusions, and applied those principles and conclu-

4 E

sions to particular diseases: hence were they called *logici*, logicians, and were distinguished from the *empirici* and *methodici*. They are what are at present styled regular scientific physicians, in opposition to quacks and Brunonians.

**DOLABRIFORMIS**, (from *dolabra*, an axe, and *forma*, likeness). In botany it means shaped like an axe.

**DO'LICHOS**, (*δολιχος*). *Long*, or *prolix*. A rod of kidney bean. See *PHASEOLUS ZURRATENSIS*.

**DO'LICHOS SOIA**, Lin. Sp. Pl. 1023; the plant which affords the soy. See *CONDIMENT*.

**DO'LICHOS PRURIENS**, Lin. Sp. Pl. 1019. From the bean of this plant the hairy covering is scraped, and given to destroy worms. See *ANTHELMINTICA*.

**DOLOI'RES**. See *DELIGATIO*.

**DO'LOR**. *PAIN*; *algema*. Boerhaave, and most other authors on this subject, assign a stretching of the nerves as the only immediate cause of pain: but this is a partial view of the subject, since compression, irritation, and many other causes, concur. See the articles *CEREBRUM*, *NERVI*, and *SYMPATHIA*.

Many kinds of pain are described by authors; as a gravitative pain, or a sense of weight on the part affected, as the liver; a pulsative pain, which always succeeds some remarkable inflammation in the containing parts, and is a symptom of suppuration; a tensive or a distending pain, excited by the distention of some nervous, muscular, or membranous part, from a fluid, or flatulence; an acute pain, when attended with quick and lively sensations; a dull pain, when attended with numbness.

The mediate and more remote causes of pain are generally obvious, and the cure will consist generally in removing them; for though, in many instances, the chief complaint is very distant from the seat of these causes, yet their removal is the most effectual method of relief. For these methods we must refer to the particular articles.

When pain is owing to inflammation, the pulse is quicker than in a natural state, generally full, hard, and tense; the pain is equal, throbbing, and unremitting.—If a spasm is the cause, the pulse is rarely affected; at intervals the pain abates, and then returns with a considerable degree of aggravation; gentle motion sometimes abates the pain; but in inflammatory pains no such relief is ever experienced.

The pains so frequently attendant on child-bed women, called after pains, from their occurring after delivery, are often occasioned by coagulated blood, which excites the action of the uterus to discharge it. Care should be taken not to confound them with the pains attending puerperal fevers, or the colic. After pains come by fits, and soon go off, but return at different intervals, usually longer each day, and after two or three days generally cease. Notwithstanding these pains, the lochia flow properly; but the violence of the pain is generally followed by the discharge of clots of coagulated blood. This is not the case in colic; and puerperal fever is attended with shivering and tumefaction, with soreness on the abdomen.

As these pains are spasmodic, opiates, with frequent draughts of warm caudle, camomile tea, &c. are only necessary. See *PUERPERALIS FEBRIS*.

Pain forms, with some nosologists, a class of diseases,

under the denomination *PAINFUL DISEASES*, because pain is the characteristic symptom and constant concomitant of such complaints, as gout, rheumatism, and colic, and these all arise either from irritation, spasm, or distention; but most commonly from the first often inducing the two last.

When pains arise on taking cold during the use of mercury, which is not unfrequently the case, a continuance or a repetition of the mercurial course is the only cure. See the third volume of the *London Medical Observations and Inquiries*, p. 244.

**DO'LOR FACIEI CRUCIANS**. We have adopted this little change from Dr. Fothergill's appellation of the *tic dolooureux*. In fact, it is a pure unmixed pain, from a nervous affection only; and, when we consider the subject of nosology, we shall find, in this, and some other diseases, a strong inducement to form an order or class of *DOLORES*.

It is an affection of a branch of the fifth pair of nerves, which passes through the infra orbital foramen to the cheeks. The pain is most excruciating, not constant, but not regularly intermittent, or ushered in by a febrile paroxysm. Opiates scarcely lull its violence, and the only remedy is the division of the nerves. It has been said that the pain returns after the operation; but we have no evidence that nervous sensation is communicated through the medium which unites the end of the wounded nerves, though some sensation is referred to the part, from an affection of the trunk, or superior branches. If there was the slightest suspicion of this kind, a portion of the divided nerve might be cut off, so that the extremities would be no longer in contact. A more common cause of the failure of the operation is, that the trunk of the nerve, when it escapes from the foramen, is not divided; but some principal branch has been mistaken for it. Dr. Fothergill, in a late treatise on the subject, has collected all that has been said on the *Tic DOLOUREUX*, q. v. The name is derived from the pungent stroke with which the pain attacks, resembling the bite of an insect.

**DOLO'RES**, vel **DOLOSOSI**, **EXTRINSECI**, and **INTRINSECI**. Painful diseases of the limbs or internal parts.

**DOMESTICUS**, (from *domus*, a house). **DOMESTIC**. In zoology it signifies animals fed at home, in distinction from those which are wild. In botany it signifies cultivated; in pharmacy, some medicines prepared for a family without the direction of a physician.

**DOMINICUM SERPENTUN**. See *BOICININGA*.

**DO'RCAS**, (from *δερκα*, to see; from the acuteness of his vision). See *CAPRA ALPINA*, and *CAPREOLUS*.

**DO'REA**. See *HEMERALOPS*.

**DO'RIA NARBONE'NSIUM**; from Andrew Doria, who brought it from Africa. *Damasonium*, *lobelii*, and *mathioli*; *alisma*; *alisma damasonium* Lin. Sp. Pl. 486. **DORIA'S WOUND WORT**. It grows on the banks of rivers, flowers in July and August, and is commended as a vulnerary, but not much employed.

**DO'RIA HE'BRA**. See *VIRGA AUREA*.

**DO'RIDIS HU'MOR**. See *AQUA MARINA*.

**DO'RIS**, (from its country). See *ANCHUSA*.

**DORO'NICUM**, (from the Arabic term *dorongi*), **LEOPARD'S BANE**.

DORO'NICUM AUSTRI'ACUM, GERMA'NICUM. See ARNICA MONTANA.

DORO'NICUM ROMA'NUM; *doronicum radice scorpii*, *aconitum pardalianches*, BROAD LEAVED LEOPARD and WOLF'S BANE; *doronicum pardalianches* Lin. Sp. Pl. 1247, var.  $\beta$ .

It is a native of the Alps; cultivated in our gardens; hath heart-shaped leaves, and roots that are knotted, and resemble a scorpion's tail. It flowers in June and July. The roots are sweetish to the taste, slightly aromatic, and extolled in epilepsies; but they are neglected at present in our practice. The plant is supposed to be the *duronego* of the Arabians.

DORSA'LIS, (from *dorsum*, the back,) belonging to the back. In botany it means a plant which bears its seed on the back of its leaves. The filices are, on this account, termed *dorsales*.

DORSA'LES NE'RVI, (from *dorsum*, the back,) the nerves which pass out from the vertebræ of the back. These dorsal nerves, as soon as they pass from the vertebræ, send out two branches anteriorly, called *costales*, which contribute to form the intercostal, and several twigs backwards to the muscles. The dorsal nerves go to the internal and external intercostal muscles, running on the under side of the ribs: those that supply the true ribs extend as far as the sternum; those that go to the spurious ribs are dispersed on the muscles of the belly. The first dorsal nerve goes to the axilla, to join the cervical; the last is diffused over the transversalis and obliqui interni; and at the spine of the os ilium it throws a branch out, forming a cutaneous nerve on the hip.

DORSTE'NIA, (from Dr. Dorston). See CONTRAYERVA.

DORSUM. The BACK. Most etymologists derive it from *deorsum*, because it bends downwards; *antisternon*, and *metaphrenon*; but this last appellation properly means the part between the shoulders. We use the term back in a figurative sense, as the back of the head; and the epithet dorsalis is applied to diseases originating apparently from the back.

A gibbosity is a preternatural incurvation of the spine of the back, either to the posterior or to the lateral parts. It generally happens from external causes, as blows, tight stays, &c.; sometimes from a relaxation of the ligaments of the belly, or from scrofula. Gouey gives an instance of it from a preternatural contraction of the muscles of the belly. See Heister's Institutes of Surgery, and DISTORTIO SPINÆ.

DORY'CNium, (from *doru*, a dart). See CISTUS.

DOSE. The quantity of medicine directed to be taken at once. See POSOLOGIA.

DO'THIEN. See FURUNCULUS.

DOUCHE LA. See DUECIA, and STILLICIDIUM.

DOVE'RI PU'LVIS, (from its inventor Dover.) See *Pulv. ipecacuanhæ comp.* under IPECACUANHA.

DRA'BA, (from *δρασσω*, to seize; so called from the sudden effect on the nose of those who eat it.) *lepidium Arabis*; ARABIAN MUSTARD and TURKEY CRESSUS. *Iberis umbellata* Lin. Sp. Pl. 906? The seeds serve as pepper in seasonings, but are not used as a medicine.

DRA'CHMA, (from the Hebrew *drachmon*). Among the Greeks this was the name of a coin; and of a weight divided into six oboli. The Romans reckoned eight drachms to an ounce, and twelve ounces to a pound:

in our apothecaries' present weights, the drachm makes three scruples, or sixty grains.

DRA'CO, (from *δρακων*, a dragon; because its flowers resemble the mouth of a dragon,) *tarachon*, *dracunculus hortensis*, *abrotanum lilii folio*, TARRAGON. *Artemisia dracunculus* Lin. Sp. Pl. 1189.

The leaves of this herb resemble those of hyssop, and their scent that of fennel: the flowers grow on the top of the plant, and appear like those of southernwood. It grows in gardens, and flowers in July and August; is warm and stomachic, used as a condiment, but not employed in medicine.

DRA'CO A'RBOR I'NDICA SILIQU'OSA. See ANG-SANA.

DRA'CO FI'GENS. The name of an anti-epileptic powder extolled by Dolæus.

DRA'CO SYLVE'STRIS. See PTARMICA.

DRACONTHÆ'MA, (from *δρακων*, a dragon, and *αἷμα*, blood. See SANGUIS DRACONIS.

DRACO'NTIA. See DRACONTIUM.

DRACO'NTIA, MINOR. See ARUM.

DRACO'NTIA MA'ORA. See DRACUNCULI.

DRACO'NTIDES; the name of some veins proceeding directly from the heart.

DRACO'NTIUM, (from *δρακων*, a dragon; from its root resembling a dragon's tail,) *dracunculus polyphyllus*, *colubrina*, *dracontia*, *Erva de Sancta Maria*, *gigarus serpentaria*, *arum polyphyllum*, DRAGON'S and MANY-LEAVED ARUM. *Arum dracunculus* Lin. Sp. Pl. 1367. It is a plant with smooth glossy leaves, set on long pedicles; the stem is single, thick, whitish, and variegated with purple streaks; on the top is a long sheath, including a dark coloured pistil, like that of arum, but larger, succeeded by a cluster of red berries. The root is large, rather round, externally inclining to yellow, and internally white. It is perennial; a native of the southern parts of Europe.

Its botanical analogy and its medical virtues render it a good substitute for the arum; and the same pharmaceutical treatment is necessary. See ARUM.

DRACU'NCULUS HORTE'NSIS, (a dim. of *draco*). See DRACO.

DRACU'NCULI, (from *δρακων*, a serpent). GUINEA WORMS; called also *capillares vermiculi*, TAPE WORM, and SOLITARY WORM. The Arabians call it *Medinensis*, vel *medena vena*. They styled it *vena*, because they doubted it being a living animal, and *Medinensis* from the frequency of its appearance at Medina. Hence Avicenna treats of it among abscesses. Le Clerc and many others mistake them for the *bovina affectio*; but Ætius separates, and Albucasis distinguishes them with great care.

Dr. Freind thinks that Ætius first gave an account of these worms; but Plutarch quotes Agartharchides on this subject long before Ætius. Plutarch calls them *δρακονίδια μικρά*.

They are common in both the Indies, in most parts of Africa, occasionally in Genoa, and other hot countries.

"These worms resemble the common worm, but are often much larger; commonly found in the legs, but sometimes in the muscular part of the arms. They are bred in Ethiopia and India, principally affecting children; and their generation is not unlike that of the broad worms of the belly; hence their name *rare*

WORM. While they move under the skin they create no trouble; but in length of time the place near the dracunculus suppurates, and the animal puts forth its head. If it be drawn, it excites considerable uneasiness, especially if drawn so forcibly as to break it; for the part left within creates intolerable pain." (Ætius in Tetrabib. 4. serm. 2. cap. 85.) Paulus Ægineta mentions them as being always seated in the muscular parts of the thighs, legs, and arms; and he says, that sometimes they are met with in the sides of children. Avicenna observes, that these worms are from ten to fifteen palms long. Albucasis mentions one of twenty palms. In the sixth vol. of the Edinb. Med. Essays, mention is made of one that was three yards and a half in length.

In some instances, besides the pain which these worms occasion, a fever is also a consequence.

Kempfer observes, that these worms prevail most when the weather is hottest; and he attributes their production to drinking stagnant rain water. Dr. Towne, in his Treatise of the Diseases of the West Indies, properly describes this worm as being long, white, round, and resembling round tape or bobbin.

Nothing is necessary until a tumour comes on; and then the best method is to promote suppuration: as soon as the tumour is open, the head of the worm appears, which, being tied by a thread, may be secured on a roll of linen spread with sticking plaster, and as the worm appears, it may be rolled round this linen, until the whole is extracted; after which, the treatment is in no respect uncommon. During the time that this worm is drawing out, the greatest care is necessary that it may not be broken, for the consequence of such an accident is tedious ulcers in the whole length of the limb which contains the remaining part. A daily use of aloes, or of any other anthelmintic, during the extraction of the worm, is supposed to hasten its expulsion.

DRACUNCULUS. See DRACO, DRACONTIUM.

DRACUNCULUS PRATE'NSIS. See PTARMICA.

DRAGACA'NTHA, DRAGA'NTUM. See GUM TRAGACANTHÆ.

DRA'GMA, and DRA'GMIS, (from δραγμα). A HANDFUL. See MANIPULUS, and PUGILUS.

DRAKE'NA RA'DIX, (from sir Francis Drake, who first brought it from America). See RADIX CONTRAVERVA.

DRANGÆ'A. A name of several antidotes. See TRAGÆA.

DRANK. See ÆGYLOPS.

DRA'STICOS, (from δραω, to act, effect, or perform). DRASTIC, ACTIVE. It is an epithet bestowed on medicines of quick action and powerful operation, commonly applied to cathartics of a violent quality. See CATHARTICA.

DRESDE'NSIS PU'LVIS; an oleo saccharum, containing the oil of cinnamon.

DRIFF. BUTLER'S STONE, or some similar preparation; also named *periapton*, *salutis magneticum*; and said to cure diseases by a touch of it with the lips and tongue. Van Helmont.

DRIMYLE'ON, and DRIMYMOROS, (from δριμυς, eager, shrewd, and λεων, a lion,) a term of reproach bestowed by Menodotus, the empiric, upon the physicians of his time, who professed to govern practice by their reason.

DRIMYPHA'GIA, (from δριμυς, acrid, and φαγω, to eat). The eating of acrid substances.

DRO'MA. The name of a plaster described by Myrepsus.

DROPA'CES, and DROPACI'SMUS, (from δρεπω, to remove). See CEROPISSUS.

DROSA'TUM, i. e. Rosatum. Wine made of roses infused, or any other composition where roses make the chief ingredient.

DRO'SERON. The name of an ointment in Myrepsus.

DROSIOBE'TANON, (from δροσος, dew, and βεταννη, an herb; from its being covered with dew). See BETONICA.

DROSOME'LI, (from δροσος, dew, and μελι, honey). See MANNA.

DRU'PAS, a contraction of δρυπεπης, (from δρυς, a tree, and πιπω, to fall). See OLEA.

DRYO'PTERIS, (from δρυς, and πτερις, fern; because it grows upon oak trees). See POLYPODIUM TENERUM MINUS.

DRY'PA, the same as DRUPAS. In botany it means a pulpy pericarpium surrounding a stone, as the peach and cherry. See OLEA.

DU'BEL CO'LEPH. A composition of coral and amber.

DU'BELECH. The cavity of an abscess, with manifest solution of continuity.

DUBLE'TUS. See ABSCESSUS.

DU'CCIA. A DROP. It implies also that species of bathing which we call pumping, and the French *la douche*. Baccius, in his Treatise of Baths, lib. ii. gives rules for this kind of bathing. See also Le Dran's Observations, p. 310.

DU'CIS HOLSA'TIÆ SAL. NITRE.

DU'CTUS, (from duco, to lead). A DUCT or CANAL; a word frequently applied to parts of the body through which particular fluids are conveyed.

DU'CTUS ARTERIO'SUS. It is found only in the foetus, and very young children, arising from the aorta descendens, immediately below the left subclavian artery. In adults it is closed up, and appears like a short ligament adhering by one end to the aorta, and by the other to the pulmonary artery; so that, in reality, it deserves no other name than that of *ligamentum arteriosum*.

DU'CTUS AU'RIS PALA'TINUS. See TUBA EUSTACHIANA.

DU'CTUS AD NASUM. See ANTRUM GENÆ.

DU'CTUS BILIARIS, and DU'CTUS COMMUNIS CHOLEDOCHUS. See JECUR.

DU'CTUS LACTIFERI. The excretory ducts from the glands of the breast, which convey the milk to the nipple.

DU'CTUS NI'GRI. On separating the crystalline and vitreous humours from their adhesions to the ciliary processes, part of the black pigment, on the choroides, is left in black radiated lines, which are thus named.

DU'CTUS PANCREATIS opens into the duodenum, near, or often at, an aperture common to it and the ductus communis choledochus.

DU'CTUS SALIVA'LIS. See SALIVA.

DU'CTUS STENO'NIS. See SALIVALIS DUCTUS STENONIS.

DU'CTUS THORA'CICUS. THORACIC DUCT. Pecquet discovered and demonstrated it at Paris, 1615, 1652. It is a thin transparent canal, which runs up from the

receptaculum chyli, along the spina dorsi, between the vena azygos and aorta, often above the fifth vertebra of the back; from thence it passes behind the aorta, towards the left side, and ascends behind the left subclavian vein, where it terminates in some subjects by a kind of vesicula; in others by several branches united together, and opens into the back side of the subclavian vein near the outside of the internal jugular. It is furnished with many semilunar valves directed upwards, to prevent regurgitation. Its opening into the subclavian vein in the human body is, in the place of valves, covered by several pelliculae, so disposed as to admit only the gradual entrance of the chyle into the vein, and hinder the blood from running into the duct. It is sometimes double, one lying on each side; and sometimes it is accompanied with appendices, called *pampiniformes*. Any compression upon this duct will occasion atrophy, and death; as it prevents the fluids by which the animal is to be nourished from entering the course of circulation. See Monro's Osteology.

**DUCTUS VENOSUS.** When the vena cava passes the liver, in the foetus, it sends off the ductus venosus, which communicates with the sinus of the vena portae; but in the adults becomes a flat ligament.

**DUCTUS WHARTONI.** From Wharton the discoverer. The inferior salival duct is thus named from his describing it.

**DUDA'IM.** See MANDRAGORA.

**DUE'LLA.** A weight of eight scruples.

**DULCA'CIDUM,** (from *dulcis*, *sweet*, and *acidum*, *sour*). Any preparation that is sweet and tart, as oxymel.

**DULCAMA'RA,** (from *dulcis*, and *amarum*, *bitter*). See SOLANUM LIGNOSUM.

**DULCE'DO SATURNI,** i. e. *cerussa*. See PLUMBUM.

**DULCE'DO VENERIS.** See CLITORIS.

**DULCIS RA'DIX.** See GLYCYRRHIZA.

**DU'LECH.** A term used by Paracelsus and Helmont for a spongy stone generated in the body.

**DULWICH WATERS.** This well is situated in the county of Surrey, about four miles south east of London-bridge. The water is clear, slightly brackish, and tastes a little bitter in the throat. A gallon at one time yielded two, at another three, drachms of solid matter, containing a small portion of calcareous earth, and a vitriolated magnesia, mixed with a portion of marine salt. From one to three pints in a morning are a dose. See AQUE MINERALES.

**DU'MUS,** (from *δύω*, *to rest under*). A BRUSH, or SHRUB. Bushes send out branches from near their roots; and are distinguished from trees, whose stem rises considerably before any branches are sent out.

**DUO'BUS,** SAL DE. See NITRUM.

**DUODENA'LIS,** or **INTESTINALIS ARTE'RIA,** (from *the intestine*, called *duodenum*). As soon as the gastrica dextra hath passed behind the stomach, it sends out the duodenal artery (which sometimes comes from the trunk of the hepatica): it runs along the duodenum, on the side next the pancreas, to both which it furnishes branches, as well as to the neighbouring part of the stomach.

**DUODENA'LIS VE'NA.** A branch from the vena portae ventralis, called *intestinalis*; it is distributed chiefly in

the duodenum, but sends some branches to the pancreas. A branch of the gastrica has the same appellation, and the hæmorrhoidalis interna gives a branch of this name to the duodenum.

**DUODE'NUM,** (from *duodeni*, *twelve*). This intestine is thus named from a supposition that its length does not exceed the breadth of twelve fingers; and if measured with the ends of the fingers, the idea is sufficiently correct: it is also called *dodecadactylon*, *ecphysis*, *portorarium*. It begins at the right orifice of the stomach behind the liver; runs backward, and obliquely downward; then turns a second time towards the right kidney, to which it is attached by the cellular membrane. It next passes between the kidney and liver, across the spine about the last vertebra of the back; and it comes out on the left side, behind the root of the mesentery: as soon as it arrives at the mesentery, it forms the jejunum. It is the widest and shortest of the small intestines; indeed it is sometimes called *ventriculus succenturiatus*, an office we have already assigned to it (see DIGESTION). Its extremity, next the jejunum, is fixed in a course almost perpendicular upwards. It is not entirely covered with the peritonæum, nor contracted by a mesentery; but attached to the neighbouring parts. Its outer coat is surrounded by a loose cellular membrane; the villi in its inside are thicker than in the stomach, and its texture resembles a fungus, as the inner coat is loose, and folded into what are called *valvulae conniventes*, like the gills of a mushroom. On the edges of these valves are very fine papillae of different shapes, apparently pierced with many holes, seen only by a magnifier; and in other parts are villous tubercles at different distances from each other. This villous substance contains many capillary vessels, not only conveying red blood, but apparently lymph or chyle. Several follicles are discovered in the cellular substance, which have been considered as the origin of the lacteals. These have been called, from their discoverer, the *ampullae of Liberkuhn*.

In the inner surface, almost at the lower part of its first turn, there is a longitudinal protuberance, at the point of which is an opening, where the pancreatic and biliary ducts discharge their contents.

As its form is much like that of the stomach, so is its use: it is furnished with fluids peculiar to itself, since not only numerous small glands were discovered by Brunnerus in it, but the pancreatic juice, mixing with the bile, accomplishes, in this intestine, the further elaboration of the chyle: thus the digestion of the aliment, begun in the stomach, is completed in the duodenum. (See DUODENALIS ARTERIA ET VENA.) Its nerves are the middle plexus of the semilunar ganglion, and some filaments of the plexus stomachicus and hepaticus. The duodenum is connected with the œsophagus by the same coats, and hence they communicate with the coat which surrounds the fauces and the mouth. Like the stomach the duodenum hath a very extensive nervous connection with the other parts of the body.

Of such importance is the duodenum, that Sylvius thinks it the seat of almost all the disorders in the physician's province. Van Helmont agrees with him; and the influence of this part is certainly considerable.

In the circulation, no morbid matter can be discovered; in the stomach and duodenum, a stagnation, and

consequent degeneracy are often produced: if the bile and other fluids stagnate in the duodenum, they soon occasion great anxiety, with other unpleasant symptoms. From this source, viz. the morbid contents of the duodenum, many disorders have been traced; and the opinion is further confirmed by the success of emetics, and of gentle purgatives, in the cure of many chronic complaints. Emetics often evacuate the contents of the duodenum by a continuation of the inverted motion, as we find by their discharging bile after their continued action. See *Monro's Observations on the Intestines*, in the *Edinburgh Essays*, and *Frederic Hoffman on the Duodenum*.

**DUPLICANA**, (from *duplex*, double.) See **TERIANA DUPLEX**.

**DUPO'NDIUM**. A weight equal to four drachms.

**DURA MATER**, (from *durus*, hard, and *mater*, mother). It is so called from its hardness, compared with that of the pia mater, and from its being the source of all the other membranes; *omenta eilamides*, *cuticularis membrana*, and *crassa meninx*, to distinguish it from the *meninx tenuis* or pia mater. See **PIA MATER**.

The dura mater, to which *dermatoides* is used as an epithet, from its skin or leather-like appearance, lies contiguous to the inside of the skull; its substance is very compact; white, and glistening like a tendon, and divided into two or more lamellæ. The external surface of this membrane is analogous to the internal surface of the periosteum in all parts of the body; it adheres more firmly to the cranium at the sutures than elsewhere, because of the vessels which run in these, and in the processes which are thrown out. The inner surface of the dura mater is, in general, a smooth membrane, and lies loose upon the pia mater, except at the sinuses, where they are attached by means of the veins which come out from the pia mater; and, sinking into the dura mater, form these cavities. The processes of the dura mater are divided into the external and the internal. The true external are those which line the foramina, which are afterwards lost in the pericranium, or accompany the nerves. These processes are accommodated, in general, to the size and direction of the nerves; but when the processes of the dura mater are mentioned, in general, the internal ones are meant. The longitudinal, or the *processus falciformis*, or *falx* (from its shape being like that of a sickle), begins at the *crista galli*; runs in the direction of the sagittal suture, to the middle of the *os occipitis*, dividing, as already explained, the cerebrum into two hemispheres; it there forms two transverse processes, which lie between the two posterior lobes of the cerebrum and cerebellum. The glands of the dura mater, spoken of by some old anatomists, do not exist. The sinuses of the dura mater are venal, though their structure and form differ from veins; every section is triangular, and their shape like a prism. The veins are every where pouring their blood into these sinuses from all parts of the brain, and there are several cords going across them, which, from their discoverer, are called *chordæ Willisii*; but the veins and sinuses of the brain have already been described (see **CEREBRUM**). The principal sinus runs along the processes. The dura mater appears more red than the tendons, because of the arteries which pass over its surface before they penetrate it. The arteries go from side to side, but do not open into the si-

nuses, as has been asserted. Wherever an artery runs upon the dura mater, it is accompanied with one or more veins, which contribute to make the sulci on the cranium, as well as the arteries. Its principal uses are as a covering for the brain; and it serves as an inner periosteum. The use of the processes is to connect the bones, and of the sinuses to retain the necessary proportion of blood.

The dura mater, when exposed in a living animal, is seen to have a pulsation corresponding to that of the arteries, owing to the systole and diastole of the arteries of the pia mater. When the dura mater is laid bare, it commonly sloughs like a tendon; in some cases it is ossified. The brain is sometimes protruded through the bregma in children, with its covering, the dura mater. Gooch, in his *Medical Observations*, gives an instance of a fractured skull, when a fluid being perceived under the dura mater, this membrane was cut through with the scissors, and the patient recovered.

The nerves have been said to arise from the fifth and seventh pair; but the modern anatomists do not acknowledge them.

**DURÆ MATRIS ARTERIÆ**, and **MENINGEÆ**. The **DURAMATRAL ARTERIES**. The external carotid artery sends a branch through the spinal hole of the *os sphenoidale*, which is the middle artery of the dura mater, and is called, by way of eminence, the *artery of the dura mater*. It is divided into many branches, which are dispersed through the substance of the external lamina as high as the falx, where these ramifications communicate with the branches on the other side. The impressions of this artery are seen on the inside of the parietal bones; the anterior and lower angle of which, instead of a simple impression, contain a canal for the passage of a trunk of this artery; on which account, several accidents happen in fractures of the skull. The external carotid sends off another branch, through the superior orbital fissure, to the dura mater, called its anterior artery; and it receives branches from the carotid and the vertebrals. Winslow calls the first mentioned of these arteries, *spheno-spinalis*. Dr. Hunter observes that the dura-matral artery proceeds from the inferior maxillary artery, and passes through a hole in the petrous part of the temporal bone.

**DURA'TUS**, (from *durus*, hard.) **HARDENED**; but in *Scribonius Largus* it means macerated.

**DURO'NEGO**. **BROAD LEAVED LEOPARD'S BANE**. See **DORONICUM ROMANUM**.

**DU'TRAY**. See **STRAMONIUM**.

**DWARFS**; diminutive beings whose growth has been checked by art, or arrested by disease. Their height differs; but, in general, they have exceeded three feet. The Polish *Borulawski* was, however, but twenty-eight inches; and *Bebe*, kept by Stanislaus, king of Poland, measured only thirty-three inches. Their intellectual faculties are, however, imperfect: they are lively, but simple; and sharp, but timorous. *Borulawski* seems to have possessed superior mental powers. It is not easy to assign a cause for such diminutive forms, except their growth is checked by disease, and their forms distorted by confinement in one posture.

**DYAMA'SSIEN**. See **ÆRIS FLOS**.

**DY'NAMIS**, (from *δυναμις*, to be able.) It is the faculty or power from whence an action proceeds.

Galen often uses this word for a composition of a medicine, particularly of an approved one.

DYO'TA, or DISTA, (from *δύω*, *two*, and *οὖς*, *ears*, *an ear*). A PELICAN, or CIRCULATING VESSEL, WITH TWO HANDLES OR EARS.

DYSÆSTHESIA, (from *δύς*, *difficulty*, and *αἰσθάνομαι*, *to feel or perceive*). A DULLNESS OF SENSATION, or FAULTY SENSE. Under this term, Dr. Cullen forms his first order of his fourth class *locales*; though in the enumeration of the species he has not adhered closely to the definition. Diseases of this order are synonymous with *hallucinationes*, according to this author, and are considered as complaints whose principal symptom is a depraved or erroneous imagination. He defines them, the senses depraved or destroyed from some defect or fault of the external organs. Privativi are reduced to this head.

DYSA'LTHES, (from *δύς*, *difficulty*, and *αλθω*, *to cure*). DIFFICULT OF CURE.

DYSANAGO'GOS, (from *δύς*, and *αναγω*, *to subdue*). An epithet for tough viscid matter, which is with difficulty expectorated.

DYSCATAPO'TIA, (from *δύς*, and *καταπίνω*, *to drink*). A difficulty of swallowing liquids, which Dr. Mead thinks a more proper term than that used for canine madness, viz. *hydrophobia*, as it is more particularly descriptive of the affection under which the unhappy patients labour; but, in reality, they dread water from the difficulty of swallowing it.

DYSCINE'SIA, (from *δύς*, and *κινεω*, *to move*). Difficulty of motion, from faulty or defective organs: also termed *intemperies*. This is the third order of Dr. Cullen's class *locales*—defined, motions impeded or depraved from the fault of the organs.

DYSCRA'SIA, (from *δύς*, and *κερυννυμι*, *to mix*). DYSCRACY. An ill temperament or habit of the blood and humours, as in the jaundice and scurvy.

DYSCRI'TOS, (from *δύς*, and *κρίσις*, *crisis*). Difficult to be brought to a crisis, or brought to an imperfect crisis.

DYSECCE'A, (from *δύς*, *difficult*, and *ακουω*, *to hear*). DEAFNESS, called also *cophosis*. Dr. Cullen places this genus of disease in the class *locales*, and order *dysæsthesiæ*, which he defines, hearing diminished or abolished. He points out two species:

1. DYSECCE'A ORGANICA, from a fault in the organs, by which sound is transmitted into the internal ear.

2. DYSECCE'A ATONICA, in which there is no manifest fault in the organs for transmitting sound into the internal ear; but merely a defect of the nervous power. See SURDITAS.

DYSE'LCES, (from *δύς*, and *ελκεω*, *an ulcer*), an epithet for such persons whose ulcers are difficult to heal.

DYSE'METI, (from *δύς*, and *εμεω*, *to vomit*). Those who vomit with difficulty.

DYSENTE'RIA, (from *δύς*, *difficult*, and *εντερον*, *the intestines*). Intestines with difficulty moved, though sometimes called *diarrhœa carnosæ* and *dissolutus morbus*, often the *blood flux*, because blood occasionally appears in the stools: this, however, is not always a symptom, nor essential to the disease. Dr. Akenside calls the dysentery a rheumatism in the bowels, and thinks dysentery and rheumatism are the same: the

Latins call it *tormina*: Cœlius Aurelianus, a rheumatism of the belly, preceded either by a diarrhœa, a cholera morbus, or a tumour of the abdomen. Dr. Cullen defines it, "a contagious fever, in which the patient has frequent mucous or bloody stools, accompanied with much griping and followed by a tenesmus; the alvine fæces being for the most part retained." The stools, though frequent, are generally small in quantity; the matter voided is chiefly mucus; sometimes blood. At the same time the natural fæces seldom appear; or they are small in quantity, compact and hardened. He places this disease in the class *pyrexia*, and order *profusiva*. There is but one species, which varies its name from different circumstances, e. g. *dysentery castrensis*, from happening in a camp, on account of the soldiers being more exposed to the night air, which produces or aggravates the disease; *dysentery verminosa*, from being occasionally accompanied with worms; *dysentery carnosæ*, when fleshy or sebaceous lumps are discharged; *dysentery intermittens*, when accompanied with an intermittent fever; *dysentery alba*, when the stools are not mixed with blood; *dysentery miliaria*, when accompanied with miliary eruptions. The others are symptomatic. This disease is sometimes acute; but more frequently of a chronic kind.

As diarrhœa and dysentery equally consist of an increased discharge by stool, the diseases have been generally confounded; and a diarrhœa, especially if attended with a discharge of blood, has been styled a dysentery. The more attentive observation of the moderns has corrected this confusion, from which even the work of Sauvages is not free; though the correction is, in a great degree, owing to the labours of nosologists.

Diarrhœa chiefly consists of the evacuation of feculent matter, for the stools, even when watery, contain dissolved fæces: in dysentery the stools are retained, and the evacuation, discharged with much straining, is a small portion of mucus only. Each is attended with pain and tenesmus: but in dysentery, the pain and straining are extremely violent. Again: the diarrhœa and dysentery are both occasionally epidemic; the latter is not only epidemic in a more extensive degree, but may be traced by infection. It is sometimes also local in its attacks, and may be traced either to the influence of neighbouring marshes, or alternates, with remitting fevers. In diarrhœa the discharges are sometimes tinged with blood; in dysentery the sanguineous discharge is often considerable: in the former, fever seldom attends, or is inflammatory only; in the latter, the fever is of the nervous and putrid kind; the prostration of strength considerable.

Various observations have been recorded to distinguish the seat of the disease, according as the blood is more or less florid, more or less intimately mixed with the fæces. These are, however, trifling, and in general unfounded. The true seat of the dysentery is the large intestines, generally their lower part; and the disease is immediately owing to a spasmodic stricture producing increased, but ineffectual, exertions on the upper part; and this spasm, to inflammation of the villous coat.

It has been common to seek for the more remote causes in acrimony of the fluids, of the ingesta, of the bile, and the other abdominal secretions. Even Sydenham, who saw clearly that it was a febrile disease,

directed to the intestines, thought it owing to a morbid matter brought by the meseric arteries. Hippocrates, however, long ago observed, that dysenteries are most common in summers that succeed cold and dry winters, followed by a rainy spring; that they occur also when a dry spring succeeds a rainy winter. Bontius remarks, that the hottest weather produces them when the nights begin to be cold. These are the periods when remittents and intermittents most prevail; when marsh miasmata are the most copious and active; when the exciting cause of cold most powerfully assists their action. In fact, it is a contagious remittent fever, with an erysipelatous affection of the internal coat of the intestines exciting a spasm, and its consequences already described; viz. increased action, sufficient to occasion the discharge of mucus, but not to evacuate the accumulated fæces. This discharge of mucus is common from every mucous membrane, when the action of the organs, which the membrane lines, is augmented, as in the bronchiæ and bladder; and we know that the fæces are retained, both from their not appearing, and from their hardened state on the solution of the disease.

The diagnostics, according to Sydenham's celebrated description, are as follow: "The patient is attacked with a chillness and shaking, which are immediately succeeded by a heat of the whole body; soon after this, gripes and stools follow: it is indeed often not preceded by a fever; but the gripes attack first, and the stools soon succeed. Intolerable gripings, and a painful descent, as it were, of the bowels, accompany every evacuation. The discharges are chiefly mucous, except now and then an excrementitious one intervenes, without any considerable pain. The mucous stools are generally streaked with blood; but sometimes no appearance thereof is seen throughout the disease: nevertheless, if the stools are frequent, mucous, and accompanied with gripings, the distemper may as justly be entitled a dysentery as if blood were discharged along with them. If the patient is in the vigour of life, or hath been treated with cardiacs, a fever arises, and the tongue is covered with a thick, white mucus; and if he hath been much heated, it is black and dry: great loss of strength, a lowness of spirits, and all the signs of an ill-conditioned fever, are joined with it. This disease is attended with extreme pain and sickness, greatly endangering life if unskilfully treated; for, when the spirits are much exhausted, and the vital heat diminished by frequent stools, before the matter can be expelled from the blood, a coldness of the extremities ensues, and there is danger of death, even within the periods of acute diseases. But if the patient escapes for this time, several symptoms of a different kind succeed. Sometimes, in the progress of the disease, instead of the sanguineous filaments, which are usually mixed with the stools in the beginning, a large quantity of pure blood, unmixed with mucus, is voided at every stool; which, as it manifests an erosion of some of the larger vessels of the intestines, threatens death. Sometimes an incurable gangrene seizes the intestines, which is caused by a violent inflammation excited by the afflux of hot acrid matter to the affected parts. At the decline of the disease, aphthæ frequently affect the internal parts of the mouth, especially if the patient hath been kept hot for a long time, and the evacuation of the matter hath been

checked by astringents; the fuel of the disease not having been first carried off by cathartics: these aphthæ generally foreshew imminent death. If the patient survives the foregoing symptoms, and the disease proves lasting, the intestines at length seem to be affected successively downwards, till it be driven to the rectum, and ends in a tenesmus; upon which the natural stools occasion great pain in the bowels, the fæces, in their passage through them, abrading the small guts; whereas the mucous stools only offend the rectum during the time that the matter is made and discharged. Though this disease is often mortal in grown persons, and especially in the aged, it is nevertheless very gentle in children, who have it sometimes for several months without any inconvenience, provided the cure of it be left to nature."

The principal distinctions of dysentery into inflammatory, putrid, and malignant, are without foundation, as will be obvious from the following short description. It is evident that these are inflammatory or putrid fevers, with inflammation in the bowels, or putrid diarrhœas.

The *inflammatory dysentery* approaches with a violent fever, and a hard pulse, which in other dysenteries is generally small, and that (only in the progress of the sickness) becomes full; an almost continued and intolerable pain in the belly, which increases on the part being touched, and still more after vomiting; stools very inconsiderable with respect to quantity; a head-ach, red face, and sometimes a distended belly.

A *putrid dysentery* is distinguished by a bitterness in the mouth, which appears directly on the first attack; a vomiting of bilious matter, which is sometimes also mingled with worms; a shivering that returns in the course of the disorder; the slightness of the fever, the paleness of the countenance, and the variegated colour of the excrements.

**DYSENTERIA MALIGNA.** A **MALIGNANT DYSENTERY** is attended in the beginning, or whenever any other kind degenerates into it, by a sudden weakness, great anxiety about the pit of the stomach, heaviness in the head, a heavy, oppressed, sunk countenance, frequent slight convulsions, a weak voice, frequent faintingst miliary eruptions, petechiæ, aphthæ, sickness, and a very weak pulse.

Having distinguished dysentery from diarrhœa, we need not add to the length of the article by enlarging on the distinction between this disease, a bloody flux from piles, or an abscess of the intestines. The description of Sydenham is alone sufficient to establish the diagnosis. The scirrhus-contracted rectum sometimes produces symptoms not unlike dysentery. The absence however, of pain, of fever, of the mucous dejections, and the troublesome tenesmus, sufficiently points out the difference.

The explanation of the symptoms, from what has been said, is not difficult. The appearance of the fatty matter, which is less easily explained, seems owing to the diseased state of the glands, from the continuance of the disease, for, apparently, it is not hardened mucus. The skins, in the stools, are probably abrasions of the villous coat. Aphthæ are a symptom of low, long continued fever, from whatever cause it may proceed.

A dysentery commonly begins as an acute disease;

but it degenerates, after some time, into a chronic complaint; and, in that case, to the other symptoms, a decayed appetite, dryness of the skin, sunk features, a lividly yellow complexion, great weakness, and emaciation, are added.

In general, the prognostics are taken from the intensity of the symptoms, the colour and smell of the stools, the strength of the patient, and the length of the disorder's continuance. It is never without danger, and never to be slightly regarded; for nature alone contributes very little to its cure. There is always danger of a mortification of the bowels, until the disease gives way. When the excrements are of various colours, and of an offensive smell, there are probably ulcers in the intestines, and the danger is increased. If blood appears on the first day, or the irritation great, the danger is in proportion. When the fever is urgent, when the cause is contagion, the patient already reduced by previous sickness, or sinking under any other disorder, the danger is proportionably enhanced. An hiccough, delirium, the pain and thirst ceasing at once, the excrements passing involuntarily, convulsions, coldness of the extremities, with vomiting, are among the mortal symptoms.

To prevent the complaint, those who are in warm climates should carefully avoid the coldness of the evenings, and the chilling dews which succeed the sultry days; those who are confined in jails, or in camps, should avoid the vapours from putrid fæces; and if any putrid disease is prevalent, the bark, with laxatives, may be taken at proper intervals. If there is any suspicion of the disease approaching, an emetic should be given immediately; a warm sudorific should succeed; and, in the morning, a dose of some gentle purgative, to promote the proper discharge from the intestines.

In the progress of this complaint, the air should be kept as pure as possible, and moderately warm: cleanliness is absolutely necessary; the excrements should be immediately removed; the linen, and every thing about the patient, frequently changed. The diet may be of rice, salop, panada, the broth of lean meat acidulated with lemon or orange juice, jelly of animal substances with cinnamon. Dr. Rutherford advises a few hand-fuls of wheat flour to be boiled, tied up tight in a rag, for six or eight hours. It will then be hard, and two or three table spoonfuls, when grated, may be boiled, in milk and water, to the consistence of pap: this may be made agreeable to the palate with sugar, and used both for the general food, and for the substance of clysters, which in this disorder are frequently required. For drink, milk and water, butter milk, the white decoction, or, what is still preferable, a decoction of mallows in milk and water, may be freely used. Frequent dilution with mucilaginous drinks of every kind is highly proper.

It was usual with Sydenham, and some other judicious practitioners, whose success justified their proceeding, to begin, if called in early after the first attack, by giving a gentle emetic, and copious draughts of some thin fluid, to cleanse the stomach: clysters of the same were frequently injected, to lessen or dilute the irritating matter if it existed; but more certainly to soften as a fomentation.

Sydenham ordered bleeding, if the symptoms required it; then directed a large quantity of cold whey to be drunk; and clysters of the same to be injected and re-

peated until the pains were abated: these were administered warm. After this the patient was put in bed, and a sweat promoted. When the patient was greatly exhausted, endeavours were used to check the evacuation.

The cure of dysentery, as described by the earlier authors, is confused and contradictory. As an increased evacuation it has been treated by astringents; as a spasm, by opiates; and as an hæmorrhage, by sedatives. Zimmerman seems to have first established the most rational views, and the most enlightened practice; yet even this requires, in different climates, considerable modifications, and numerous auxiliaries. Navy and army surgeons assert that practitioners, in general, know little of dysentery. They seldom, indeed, see the complicated cases, the numerous forms of the disease, or its singular changes. We shall give a consistent view of their doctrines and opinions, for it is one of the few diseases where we do not speak from any very extensive practice of our own. Our predecessors were certainly little acquainted with it.

As an inflammation, *bleeding* may appear the most proper step in the earliest stages; but the fever is of the putrid kind, and the inflammation erysipelatous. We find some army surgeons bleeding the strong, robust soldiers, on a violent attack in the earliest stages, with apparent advantage. It is not, however, a remedy adapted to the nature of the disease; and, though occasionally admissible, should be rarely employed.

*Emetics*, particularly the antimonial ones, are of more importance; they are adapted to the disease as febrile, and peculiarly to spasm, since, on their first action, a general relaxation is produced in the system. This relaxation is more considerable, and longer continued by giving nauseating doses only; and it is probable that the ipecacuanha, the antimonials in their various forms, the white vitriol, &c. act as much by the nausea they produce, as by increasing the discharge from the skin. Vomiting, except in the commencement, cannot be encouraged with advantage.

As the fæces are retained, *cathartics* would appear peculiarly proper; and when some relaxation of the spasm has been produced, they are found to be the most effectual remedies. Zimmerman rests chiefly on the use of the milder laxatives, neutral salts, the tamarinds, senna, and manna; and it will be indeed obvious that these, as well by their cooling as their relaxing power, must be useful. The narcotic laxatives, which we have described as producing so general a solution of tension through the whole system, may perhaps be found useful, particularly the tobacco; yet the great previous debility renders its use highly precarious, and we know not that it has been employed. Dr. Hagstroom, from the idea of dysentery proceeding from animalcules, employed the *nux vomica*, he says, with considerable success. This medicine is, indeed, a powerful narcotic, but, we believe, not a laxative.

The more active purgatives have not been lately employed. Respecting the utility of rhubarb, practitioners have greatly differed. By some it has been considered as a specific, by others as injurious. In general, it is too violent in its operation, and is by the best practitioners now disregarded. In the *Amænitates Academicæ* is a thesis, formerly quoted, entitled *Exanthemata Viva*, where the author asserts, that he has discovered animalcules in the dysentery, to which he attributes

the disease; and he thinks it a great support of his idea, that they were immediately destroyed by an infusion of rhubarb.

*Diaphoretics* are the most important medicines in this complaint; and to the relaxation of the skin must be attributed the good effects of ipecacuanha; of the vitrum ceratum antimonii; and, in some measure, of opiates. The more violent stimulant sudorifics have been avoided; and, from our observations on cathartics, it will be obvious that they must be injurious; yet ipecacuanha seems also to possess a peculiar sedative power, which renders it useful in all cases of increased action of the intestines; nor is it without reason that Dr. Akenside seems to have commended it so warmly.

The action of diaphoretics must, however, be supported by warm diluting liquors; by proper, though not heavy, bed clothes; and every method of supporting a gentle, free perspiration, approaching at least to sweating, for the patient should not sweat profusely. The object is rather to produce a general relaxation than to weaken by the discharge.

*Sedatives* have not been much employed; and when opiates have been given to lull the violence of the pain, practitioners have rather aimed at procuring present ease than at removing the complaint. But, from the view we have taken, it will be obvious that opium is of considerable service. It is singular that the opium with ipecacuanha, Dover's powder, has not been more frequently used. We suspect that its action as a sudorific is too violent; and that the disease, like other fevers, is more effectually removed by a gentle diaphoresis, than a more considerable discharge from the skin.

As the discharge of either mucus or blood is often violent, it is not surprising that astringents have been employed. All the variety have been given, and each has been commended by its partisans. Alum, gall nuts, white vitriol, logwood, simarouba, cascarilla, columbo root, and a variety of similar medicines, have been employed in this disease; but their good effects have, we believe, been owing to an unsuspected source. The gall nut is, indeed, a pure astringent, though not without some suspicion of a narcotic power. Alum is not only a sedative but a purgative, and an useful remedy in many cases of colic. The white vitriol is a tonic and a sedative; the logwood combines, with its astringency, no inconsiderable portion of mucilage. The simarouba, like its botanical associate, unites with its bitter a warm diaphoretic power; the columbo root differs little from common bitters, which alone are not astringent. Of all these supposed astringents, therefore, the cascarilla only acts as probably such; and for these reasons they have, perhaps, not been so injurious as they would have otherwise been found, for astringents are certainly not adapted to the disease: and, though we find the acacia, or its substitute, the conserve of sloes, and the catechu, sometimes mentioned, they have been long neglected by the best modern practitioners. If even the more powerful tonics are ever employed, the intestines must be previously emptied, and all inflammation removed. This is, perhaps, also the only time for the exhibition of the cascarilla.

Goettlieb Richter, in his Medical and Surgical Observations, observes, that the dysentery is a rheumatic or catarrhus affection of the larger intestines; and that the proper remedies for the disease are sedatives and

diaphoretics. In three epidemic dysenteries, which he carefully and accurately observed, he was fully convinced that the bilious appearances were accidental and accessory; and he produces several facts to prove that the bilious acrimony was not the cause of the disease, but rather the effect of irritation in the bowels, producing an increased secretion of bile, and that they had no essential influence on the principal complaint.

From this view, he depended upon opium and antimony for the cure, which they effected by allaying pain and irritation, and raising a gentle diaphoresis. He asserts also, that by the use of opium the bilious symptoms disappeared, and the patient was cured without evacuation. He does not totally reject vomits and purgatives; but if they are indicated at the beginning of the disease, he administers them. Vomits evacuate the bile, diminish the spasm in the intestines, and promote a gentle perspiration; for which purpose, he prefers ipecacuanha to emetic tartar; to clear the intestines, manna; but more particularly calomel, which from experience he found more powerful and more gentle than other purgatives; and so far from increasing the pains in the bowels, it frequently diminishes them. Rhubarb he considers as a very dangerous medicine in this disease; though, after it is cured, he approves of it as a strengthener of the stomach and intestines. When the fever is considerable, the antimon. tartarisatum, in small doses, was given, with sal ammoniac, or Mindererus' spirit. When inconsiderable, tinct. thebaic. with vinum antimonii Huxhami; or extr. opii with ipecacuanha. But in order to cure the disease radically, the use of opium must be continued, and emetics given at intervals, if necessary. A soft pulse, and moist skin, are the chief signs of the good effects of opium, and of a certain amendment. Warm fomentations to the abdomen; and frictions, with volatile camphorated liniment, were useful: but if there was a fixed pain in the belly, or they were constant, a blister on the abdomen produced the best effects. In cases where the evacuations were very fetid, and the patient much debilitated, the arnica was very useful; and when a lientery remained after the disease, the columbo root exceeded all other remedies.

The *chronic dysentery* is a very different complaint, and has not been so fully considered as it deserves. After the acute disease is removed, a tenderness of the bowels remains. They are excited to action frequently, and by the slightest causes; the stools are small, mucous, and often offensive, with frequent pains; the strength and appetite greatly impaired; the skin dry; the complexion of a dark yellow; and the eyes sunk. Either from the original cause, the climate, in which it occurred, or the disease itself, the power of the digestive organs is frequently impaired, and the liver often injured. The blood is confined to the larger vessels, and the determination to the surface greatly diminished. The remaining disease of the intestines seems to be a chronic, crispelatus inflammation, a defect of mucus, and often, perhaps, an erosion of the villous coat.

In this state of the complaint, tonics have little power. A mild, nutritious diet; the lighter bitters, as the columbo root, and the camomile flowers; a warm climate; or flannel clothing; are chiefly necessary. The increased action of the larger intestines often requires opium to be injected in a clyster; and we have found

equal parts of soap and wax, with a small portion of the pulvis Doveri, of considerable service. The soap renders the wax soluble in our fluids; and, together, they supply the abraded mucus, while the Dover's powder not only checks the too violent action of the bowels, but determines to the surface. With every exertion, however, the disease is only palliated. The patient must rest contented with infirm health during the remainder of his existence. We mean not to say that every dysentery terminates in this state; but every violent dysentery leaves some unpleasant remains of this kind.

See Alex. Trallian; Aretæus; Cælius Aurelianus, and Celsus; Baker on the Dysentery; Akenside's Commentary; Zimmerman on the Dysentery, translated by Hopson; Degner de Dysenteria; Wallis's Sydenham; Dr. Wilson on the Dysentery; Cullen's First Lines, vol. iii. p. 101. edit. 4; Moseley on Tropical Diseases; Lond. Med. Journ. vol. ii. p. 86, iii. 189. vol. vii. p. 337; Goettlieb Richter's work before quoted.

DYSENTERIA A CATHARTICIS, and PARISTACA. DIARRHŒA MUCOSA. See DIARRHŒA.

DYSEPULO'TICUS, (from *δυσ*, difficult, and *επούλω*, to cicatrise). An epithet for an ulcer which is difficult to heal.

DYSHŒMORRHOIS, (from *δυσ*, and *αιμορροίς*, the piles). Suppression of the bleeding piles.

DYSHE'LCES, (from *δυσ*, male, and *έλκος*, ulcer). Ulcers with difficulty cured.

DYSI'ATOS, (from *δυσ*, difficulty, and *ιασμαι*, to heal or cure). Difficult of cure.

DYSLO'CHIA, (from *δυσ*, and *λοχία*, lochia). Suppression of the lochia. See LOCHIA.

DYSMENORRHŒA, (from *δυσ*, and *μηνόρροίς*, menses). Difficult or painful menstruation. See MENSES DEFICIENTES.

DYSO'DES, (from *δυσ*, bad, and *ὀσμή*, to smell). AN ILL SMELL, FETID. Fœsius thinks that in Hippocrates it means a fetid disorder of the small intestines. It is also the name of a malagma for the pleurisy, and of an acopon, which Galen and Paulus describe. Sauvages, and some other nosologists, form a genus of disorder which they name dysodia, and define it to be disagreeable exhalation from the whole body, or from a particular part, the skin, the mouth, or the feet.

Dr. Percival takes notice of a kind of offensive breath, (dysodes pulmonica,) often found in persons with a narrow chest and scorbutic habit. He observes, that it seems to originate from a want of power to make a full expiration, by which too much perspirable matter is retained, and corrupted by stagnation in the vesicles of the lungs. In such cases he hath found the most salutary effects from the use of myrrh and fixed air, internally administered. These antiseptic substances are probably carried to the lungs, and correct the offensive vapour at the same time that they invigorate the smallest ramifications of the bronchiæ.

DYSO'PIA, (from *δυσ*, difficult, and *ὄψις*, visus). DIFFICULT SIGHT; *parorasis*. Dr. Cullen places this genus of disease in the class *locales*, and order *dysæsthesiæ*, which he defines, depraved vision, so that objects cannot be seen, except in a certain degree of light, at a given distance, or in a particular position. He distinguishes five species.

1. DYSO'PIA TENEBRARUM, AMBLYOPIA CREPUS-

CULARIS: when a great light is required for distinct vision.

2. DYSO'PIA LUMINIS, *amblyopia meridiana*, when sight is most distinct in an obscure light.

3. DYSO'PIA, called also *amblyopia dissitorum*, when objects must be very near to be seen.

4. DYSO'PIA AMBLYOPIA, *D. proximorum*, when objects cannot be seen distinctly, if very near.

5. DYSO'PIA LATERALIS, also called *amblyopia luscorum*, when objects are best discerned by a side view.

In the first case, the disease depends on weakness of sight; in the second from too great irritability of the organ. In persons whose hair is white, and the edges of the eye lids red, the pigment, usually black, is of a lighter colour, as in cats and the white rabbits. The rays of light are therefore not lost, as when the pigment is black; and strong light occasions pain. Every one has experienced, in a strong sunshine, the effect of

"Tenebræ per tantum lumen obortæ."

The third and fourth species are the presbytia and myopia; and the fifth depends on some partial obfuscation of the cornea, or humours, or a partial paralysis of the retina.

DYSORE'XIA, (from *δυσ*, bad, and *ορεξις*, appetite). A BAD, OR A DEPRAVED APPETITE, as when the appetite is weakened, excessive, or requires unusual food; it is synonymous with *hyperæsthesis*, *morositates*, and *privativi*. This is the second order of Dr. Cullen's *locales*, which he divides into two sections, *appetitus erronei*, and *deficientes*; Synop. Nosol. Meth. (See ANOREXIA). He places *morbi pathetici* as synonymous, p. 318, 324.

DYSPE'PSIA, from *δυσ*, difficult or bad, and *πεπλω*, to concoct). DIFFICULTY OF, OR RATHER DEPRAVED, DIGESTION. See APEPSIA.

DYSPHA'GIA, (from *δυσ*, and *φαγω*, to eat). Dr. Cullen ranks this under his class *locales*, and order *dyscinesiæ*, and defines it, impeded deglutition, unattended with inflammatory affection, or injured respiration. See DEGLUTITIO.

DYSPERMATISMUS, (from *δυσ*, difficult, and *σπερματίζω*, semino,) *agenesia*. Dr. Cullen places this genus of disease in the class *locales*, and order *epischeses*, which he defines a slow or impeded emission in coition of the semen virile, insufficient for the purpose of generation. The first species is,

1. DYSPERMATISMUS URETHRALIS, when the cause of obstruction is in the urethra.

2. DYSPERMATISMUS NODOSUS, when a tumour is formed in either corpus cavernosum penis.

3. DYSPERMATISMUS PRÆPUTIALIS, when the impediment is from a straitness of the orifice of the prepuce.

4. DYSPERMATISMUS MUCOSUS, when the urethra is obstructed by a viscid mucus.

5. DYSPERMATISMUS HYPERTONICUS, when there is an excess of erection of the penis.

6. DYSPERMATISMUS EPILEPTICUS, from epileptic fits coming on during coition.

7. DYSPERMATISMUS EPHRACTODES, from a want of vigour in the genitals.

8. DYSPERMATISMUS REFLUUS, in which the semen is thrown back into the urinary bladder. See STERILITAS.

DYSPHO'NIA, (from *δυσ*, *difficulty*, and *φωνή*, *the voice*). A difficulty of speech.

DYSPNŒ'A. DIFFICULT BREATHING, (from *δυσ*, *difficulty*, and *πνέω*, *to breathe*). *Dyspnoea*. This is a genus of the class *neuroses*, and order *spasmi*. Dr. Cullen defines it to be a constant difficulty of breathing, without a sense of straitness in the breast, but rather that of fulness and obstruction; a cough frequently attending through the whole course of the disease. He distinguishes eight species.

1. DYSPNŒ'A CATARRHALIS, when with a cough there are copious discharges of viscid mucus, called also *asthma catarrhale*, *pneumodes*, *pneumonicum*, and *pituitosum*.

2. DYSPNŒ'A SICCA, when there is a cough without any considerable discharge.

3. DYSPNŒ'A AEREA, when the disease is much increased by slight changes of the weather.

4. DYSPNŒ'A TERREA, when earthy or calculous matters are spit up.

5. DYSPNŒ'A AQUOSA, when there is a scarcity of urine, and œdematous feet, without any symptoms of a dropsy in the chest.

6. DYSPNŒ'A PINGUEDINOSA, from corpulency.

7. DYSPNŒ'A THORACICA, when parts surrounding the chest are injured or deformed.

8. DYSPNŒ'A EXTRINSECA, from manifest external causes, *asthma pulverulentorum*, and *metallicum*.

It is spoken of by many as a species of asthma; but much difficulty attends this view of the complaint, and as much in affording relief. If respiration be only obstructed and quick, without the other symptom, it is called *dyspnœa*; if attended with different symptoms, they give an appropriate name. To this place belong several of the species of the orthopnœa, to which the reader is referred.

It is, in general, a spasm affecting the vital functions. Sauvages defines it, a disease whose principal symptom is a shortness of breathing, with chronic indisposition, not intermitting, and without signs of hydrothorax or empyema. Its most usual causes are, phlegm lodged in the bronchiæ, or the too strong constriction of the bronchiæ themselves, which prevents the easy ingress of the air into the lungs. Sauvages enumerates no less than twenty-two species: but the greater number are symptomatic; and few, if any, admit of more effectual remedies than such as mitigate their violence. It is generally advisable to moderate the plethora in the lungs, and avoid all hurry of respiration.

Sometimes nauseating emetics are good expectorants in this case, especially if given in small doses. Gum ammoniacum, and asafetida, may be employed; and blisters are often beneficial. Issues have been formed in the thigh; and in some cases seem to have been useful, but in too many instances fail. See *ASTHMA*.

DYSPNO'ON. See *DYSPNŒA*.

DYSRA'CHITIS. The name of a plaster in Galen.

DYSTHERAPEU'TOS, (from *δυσ*, *difficulty*, and *θεραπεύω*, *to heal*). Difficult to heal.

DYSTO'CHIA, (from *δυσ*, *difficult*, and *τίχω*, *to bring forth young*). Difficulty in labour or child birth.

DYSTŒCHI'ASIS, (from *δυσ*, *bad*, and *στοιχῶ*, *order*), an irregular disposition of the hairs in the eye lids.

DYSU'RIA. DYSURY, (from *δυσ*, *painful*, and *ουρῶν*, *urine*). A difficulty of voiding the urine; *stilticidium*, *ardor urinæ*, *culbicio*, obstruction, heat, difficulty of voiding urine, and strangury.

A total suppression is called *ischuria*; a partial suppression *dysuria*; and this may be with or without heat. When there are frequent painful or uneasy urgings to discharge the urine, and it passes off only by drops, or in very small quantities, the disease is called a *strangury*. When a sense of pain or heat attends the discharge, it passes with difficulty, and is styled *heat of the urine*.

The dysuria is acute or chronic. Dr. Cullen places this disease in the class *locales*, and order *epischeses*, and defines it, a painful, and by some means impeded, emission of urine. He distinguishes six species.

1. DYSU'RIA ARDENS, when the urine burns in passing off, and there is not any evident disorder in the bladder.

2. DYSU'RIA SPASMODICA, when a spasm affects the parts which communicate with, and are communicated to, the neck of the bladder.

3. DYSU'RIA COMPRESSIONIS, from parts contiguous pressing on the bladder.

4. DYSU'RIA PHLOGISTICA, when the parts around are inflamed.

5. DYSU'RIA IRRITATA, when there are signs of a stone in the vesica.

6. DYSU'RIA MUCOSA, when there is a copious excretion of mucus; also called *vesicæ catarrhus*; *chylaria*; if the mucous urine is whitish; *pyuria*, *pyuria arthritica*, vel *viscida*.

The causes are various: as, caruncles in the urethra; a stone in the neck of the bladder, or in the urethra; spasm, or inflammation in either; acrimony in the urine, abrading the mucus from either; the venereal disease, and the scurvy; and ulcer, or a deficiency of mucus for lubricating the urinary passages. The chronic dysury is generally occasioned by a metastasis of gout; sometimes, it is said, of scurvy, or rheumatism; but we know distinctly of no such effect, except from gout, or the irritation of a stone. Catarrhus vesicæ sometimes leaves a tender state of this organ easily excited to inflammation by accidental cold; by excess in the use of spirituous liquors; and from hence, perhaps, sometimes supposed to be rheumatic.

The diagnostic signs of a dysury sometimes so much resemble those of a stone in the bladder, that no little difficulty attends the distinction, especially when the dysury is of the chronic kind. However, in general, the difficulty of discharging urine is unattended with pain or heat, except during the endeavours to void it, or its actual passing off; and for a short time the pain perceived afterwards is in the glans, a circumstance not so particularly attendant in the stone: in the chronic dysury, bloody urine is more frequently caused by exercise, and voided in large quantities after violent exertions than in calculus; the pain does not come on in violent paroxysms without an evident cause; tenesmus more seldom attends; nor is the flow of urine, when begun, at once checked.

Heat of urine does not arise from an increase of its natural heat; but from its irritating a tender, and often an inflamed, part. If the burning heat proceed from acrimony in the urine, it will be known by the high

colour and paucity of the discharge, or from a mixture of unusual matter.

Blood, and sometimes pus, when in contact with the neck of the bladder, produce violent pain. The discharge of mucus appears rather to be the effect than the cause of pain; but, in both, the pain is felt at the extremity of the glans, for, when any membrane is affected, the irritation is chiefly felt at its most sensible termination: thus irritation, in any of the small branches of the aspera arteria, is sensible only at its upper part; and a stone, even in the pelvis of the kidney, is felt at the extremity of the glans penis.

The dysuria is not a dangerous disorder; but it is both troublesome and difficult of cure, particularly in the aged. The principal distinction necessary in this disease is, to ascertain the nature of the discharge. Dysuria is usually attended with a mucous sediment in the urine, which is sometimes mistaken for pus. The mucus is, however, white, light, and flocculent, without smell: pus more filamentous, heavy, and of a greenish colour, with, generally, some fever; often remitting.

The cure must greatly depend on the cause. We have remarked that we seldom perceive the influence of acrimony except in gout; we meant of acrimony generated in the constitution, for, large quantities of spices, even of spirits, particularly gin, will produce it; and the stimulus of cantharides from a blister is a very common cause. In every instance of dysuria, dilution is necessary; and it is of service to give the diluting liquors in a mucilaginous form. Gum arabic, the althæa root, the jelly of the orchis (salep), infusion of linseed, of oatmeal, and barley, have been employed. There is little foundation for choice, since each is effectual, in proportion to its quantity of mucilage; and in this respect they do not generally differ: the gum arabic, in barley water, is as effectual as any other; but from one to two ounces of the gum should be taken daily. An elegant form of althæa, styled *pâte de Gaimauve*, we have found very useful; more so, perhaps, because it is pleasant, and taken, on that account, more freely. Injecting these fluids is useless, for the injection does not penetrate far into the urethra; and, except in cases of gonorrhœa, the seat of the complaint is very distant.

Bathing the penis, and particularly its glans, will often relieve, by communicating the relaxation to the vessels above, the only way in which injections can be useful; and warm brandy, or other stimulant applications to the perinæum, will be often beneficial. A blister to that part, removed before any of the cantharides can be absorbed, is equally effectual. A starch clyster, with opium, may be considered as an external application, since it is external to the part affected, and often almost immediately relieves.

Internally, opium and camphor are highly useful. The cooling power of the latter is very soon felt in the urinary organs, and it appears to be quickly effectual. In the form of Dover's powder we have found the opium particularly useful. Cooling laxatives and diuretics, which operate without any stimulus, particularly the neutral purging salts, often relieve. Nitre, which seems in almost every view useful, is suspected of sometimes irritating the neck of the bladder. If employed, it should be given in small quantities, copiously diluted, and generally with camphor. Oil has been recom-

mended, and particularly olive oil, as a laxative; but it is not peculiarly beneficial: the balsams, except in chronic dysuria, from weakness, are generally injurious. When dysuria arises from caruncles, bougies are necessary.

In the chronic dysuria, after other means fail, a salivation excited by the use of mercury has succeeded; and an issue in the inside of one thigh, a little above the knee, is said to have prevented the return, or at least rendered relapses very moderate; and this effect may, perhaps, follow, if the disease arises from gout. When the patient is too weak to admit of salivation, a dose of the uva ursi may be taken every morning, and after it half a pint of lime water, mixed with a strong decoction of the great water-dock root. The uva ursi, however, though warmly recommended in this complaint, has seldom succeeded in our hands, and never except it be taken in enormous doses.

Dr. Percival observes, that there is a species of chronic dysuria to which persons of an arthritic or scorbutic habit, and who have passed the meridian of life, are peculiarly liable. It is often mistaken for the stone, and aggravated by the use of lithontriptics. He adds, that it hath many symptoms in common with that disorder: such as frequent and urgent calls to make water; pain at the extremity of the urethra; a mucous discharge; tenesmus, and sometimes a suppression of urine. But the patients who labour under it feel no uneasy weight in the perinæum, and always void their water with much less difficulty in an erect than in a horizontal posture. The complaint, also, may be further distinguished from the stone, by having shorter intervals of ease; by more frequently injuring the retentive power of the bladder; and by occasioning no sudden interruption to the stream of urine in the absence of pain. It seems to arise from a catarrh on, and increased sensibility of, the coats of the bladder, as we have already explained. The efforts to discharge the urine should, however, be restrained as much as possible, because they increase the pain and irritation. Of all the remedies which Dr. Percival tried, he says that mercury was the most successful; it seldom failed to afford relief, and generally cured, if administered with perseverance and in sufficient quantity. According to the urgency of the case, one, two, or three scruples of the ungu. hydrargyri fortius should be rubbed into the thighs every night, till a slight ptyalism ensues: the symptoms for the most part abate before the spitting comes on; and after it has continued a little while, they disappear. Sometimes, in slighter cases, he advises half a grain of calomel, with two grains of James's fever powder, twice a day; and this small dose of mercury, if duly continued, will effect a cure, without producing any salivation, or even soreness of the mouth. In such cases, however, an affection of the prostate gland may be suspected to have been the cause; and it so frequently occasions chronic dysuria, that its state should be always ascertained by examination, if chronic dysuria is obstinate. *Sec Lond. Med. Journ.*, vol. iv. p. 69.

Violent heat in the urinary passages of women has been cured by the use of the bark.

## E.

## E B R

**E**ATON'S STYPTIC. A quack remedy for checking hæmorrhages: it consists of calcined vitriolated iron, steeped in brandy.

**EAU DE LUCE.** Sps. AMMONIÆ SUCCINATUS. See ALCALI.

**EAU DE RABEL,** consists of one part of sulphuric acid added to three of alcohol; chiefly useful in increased mucous evacuations.

**E'BEL.** The seed of sage, or of juniper.

**EBE'SMECH.** A name in Langius for quicksilver.

**E'BISCUS.** See ALTHEA.

**EBRACTEA'TUS.** Without a bractea or floral leaf.

**EBRIECA'TUM,** (from *ebrio*, to be drunk). By this term Paracelsus expresses the partial loss of reason from drunkenness; and by the addition of the word *cælestic*, that kind of enthusiasm which is affected by many heathen priests.

**EBRI'ETAS,** (from the same). **DRUNKENNESS.** Spirituous liquors animate, and for a time our natural vigour is more active; but this effect is fleeting. If they are often repeated, or too freely used, their excess of action enervates the constitution; the appetite and the digestion are impaired; the spirits fail; and a general feebleness ensues.

The effects of spirits on the human body have not been discussed with philosophical precision, nor is this the place for the enquiry. It has been generally supposed that alcohol is a stimulant, and that the repeated stimulus exhausts the excitability. From every experiment, however, on the nerves, it has been found a sedative; and those who trust in such conclusions have supposed, as usual, that it combines a stimulant power. Were we inclined to form systems, we should endeavour to show that it is really a sedative, and that its apparent stimulus is only an instance of irregular, rather than increased, action. Whatever be the source, its secondary effects are allowed to be highly sedative; and from the diminution of irritability, the most fatal effects are derived, particularly indurations of the liver, which have been ridiculously attributed to its coagulating the blood.

To relieve the effects of ebriety, we must employ moderate stimulants and tonics, particularly those which contain no portion of ardent spirits. The most effectual are the Bath waters, carbonated ammonia, or even the pure alkali; light bitters with aromatics. The most difficult, but the most essential, part of the cure, is to

## E B U

prevent the continuance of the practice. This can be seldom attained; never, it is said, with females; but men will sometimes "turn from the error of their ways." As the want of irritability is chiefly felt in the liver, its circulation should be assisted by a gentle, steady stimulus to its ducts, by those laxatives which assist the secretion of bile.

When the over-night's potation has been too liberal, a wet napkin should be bound round the head; a quantity of cold water should be placed at the bed-side; and if a restlessness comes on with heat, a dryness of the tongue, &c. this water should be drunk as freely as the thirst requires: thus, by degrees, a perspiration is produced, and the most effectual relief obtained. On the succeeding day, abstemiousness is requisite; and such a regimen should be pursued as is consistent with the nature of the constitution. A man of a strong, healthy, plethoric habit should drink plentifully of thin, warm, diluting liquids, mixed with vegetable acids; keep in bed, and promote perspiration. The weak, delicate, and relaxed, besides abstinence from solid diet, should ride on horseback, or take some other gentle exercise in the pure air; a glass or two of generous wine, as a cordial, may be allowed, or such other means pursued as are calculated to invigorate the system, and keep up an increased state of insensible perspiration. See Wallis on Health and Disease.

To the most violent effects of fermented spirits vinegar is an antidote. A sponge dipped in vinegar should be frequently applied to the mouth and nose; an emetic that operates quickly should be given; a clyster, and, after it, a purging draught, may be administered; and a gentle sweat promoted.

**EBSHAME'NSIS SAL.** See CATHARTICUS SAL.

**EBULLITION.** BOILING. The rapid separation of aeriform bubbles, in consequence of the application of heat to any fluid. These bubbles are in the state of vesicular vapours, and no permanent aeriform fluid is produced without some further chemical change.

**E'BULUS,** (from *ebullio*, to boil; from its supposed power of concocting the humours of the body,) *chamæacte*, *sambucus humilis*, *sambucus herbacea*, WALL WORT, DANE WORT, and DWARF ELDER: *sambucus ebulus* Lin. Sp. Pl. 385.

It is an herbaceous plant, dying to the ground in winter, with longer leaves than those of the elder tree, and

nine leaves on one rib. It grows wild in many parts of England, flowers in July, and produces ripe black berries in the beginning of September.

Its virtues are the same as those of the common elder, but it is somewhat more efficacious. It is an active hydragogue, and in smaller doses a powerful resolvent and deobstruent. See Cullen's *Materia Medica*; Wallis's *Sydenham*.

E'BUR, IVORY, (from *è* and *barrus*, the elephant, because ivory comes from that animal,) see SPIDIUM ARABUM.

E'BUR FO'SSILE. See UNICORNU.

ECALCARA'TUS, (from *è*, without, and *calcar*, a spur). In botany it means having no spur.

ECAUDA'TUS, (from *è*, and *cauda*, a tail). Not having the elongation of the base of a leaf, called its tail.

ECBO'LION, (from *ἐκβαλλω*, to cast out). See DIECEOLION, hence DIECBOLICA.

ECBRA'SMATA, (from *ἐκβρασσω*, to cast out, or from *βραζω*, to be very hot,) *ecchymata*, *ardentes papulæ*. Fiery pustules on the surface of the body.

ECBRA'SMUS, (from *ἐκβραζω*, to become hot). See FERMENTATIO.

ECBYRSO'MATA, (from *εκ*, out of, and *βυρσα*, a skin). Protuberances of the bones at the joint, which appear through the skin.

ECCATHA'RTICA, (from *εκ*, and *καθαίρω*, to purge). Remedies which, applied to the skin, are supposed to open the pores; but in general they are understood to be deobstruents: sometimes expectorants and purgatives are distinguished by this appellation.

ECCHYLO'MA, (from *εκ*, and *χυλος*, a juice). See EXTRACTUM.

ECCHY'MATA, (from *εκχυω*, to pour out). See ECHBRASATA.

ECCHYMO'MA ARTERIO'SUM, (from the same). The false aneurism. See ANEURISMA.

ECCRY'SIS, (from *εκκρινω*, to flow out,) is an excretion, expulsion, or removal of any excrementitious or morbid matter from the body, either by the bowels or any other convenient passage. It sometimes means the excreted matter itself. Apocrisis, a similar term according to Hippocrates, is applied to the contagious effluvia of the air, or to a morbid quality communicated to the air by exhalations, called *miasmata*.

ECCYMO'SIS, ECCHYMO'MA, (from *εκχυω*, to pour out, or from *ἐξ*, without, and *χυμῶς*, juice,) *exsuscatio*. Sometimes CRUSTULA and SUGILLATIO are applied in this sense; which see. It is an effusion of humours from their respective vessels under the integuments; either from a relaxation of the exhalants, or a bruise and consequent rupture of the vessels themselves. This blood, when collected under the skin, is called an *ecchymosis*; the skin in the mean time remaining entire, sometimes a tumour is formed by it, which is soft and livid, and generally without pain. If the quantity of blood is not considerable, it is usually again absorbed; if great, it sometimes suppurates; and any further inconvenience seldom follows: a mortification may, however, be the result in diseased or languid habits. Dr. Cullen places this genus of disease in the class *locales*, and order *tumores*, and defines it, a diffused tumour, a little elevated, growing blue or black. The causes are, pressure or bruises: from the latter the *ecchymoses* are called *stigmata*. They sometimes also arise

from blood letting, either in consequence of the orifice in the skin sliding over that of the vein, or from the vein being cut through. Livid or black spots are sometimes a symptom of the scurvy: when round and small, they are named *thrombi*; when more diffused, *ecchymoses*. It should not be mistaken for a spurious aneurism. See ANEURISM.

In slight cases, compresses dipped in vinegar, or in water so strongly impregnated with salt as to suspend an egg, frequently applied and kept upon the part, are alone necessary. If the *ecchymosis* tend to suppuration, it must be treated as an abscess. If the quantity of coagulated blood be considerable, it must be discharged by as many incisions as are requisite; then treated as an approaching mortification. See Bell's, White's, and Heister's *Surgery*. Van Swieten's *Commentaries* on Boerhaave's *Aphorisms*, sect. 324, 1151.

ECCLY'SIS, (from *εκκλινω*, to bend, or turn aside). See LUXATIO.

E'CCOPE, (from *εκκοπῶ*, to cut off). The cutting off of any part.

ECCOPE'US (from *εκ*, and *κοπῶ*, to cut). An ancient instrument, of the same use as the modern raspator.

ECCOPRO'TICA, (from *εκ*, and *κοπρος*, dung,) *coprocritica*. Mild aperients, or gently purging medicines which assist the natural evacuation by stool. See CATARTICA.

ECCRINOLO'GICA, (from *εκκρινω*, to secrete, or secrete). That part of medicine which relates to the doctrine of excretions.

E'CDORA, (from *εκ*, and *δερω*, to excoriate). See EXCORIATIO. An excoriation of the urethra. P. Amanus.

ECHECO'LLON, (from *εκ*, and *κολλα*, glue). A GLUTINOUS TOPIC.

ECHETRO'SIS. See BRYONIA ALBA.

ECHINA'TA SE'MINA. Seeds which are prickly and rough, from *echinus*, a HEDGE HOG.

ECHINI'DES. A medicine for purging the womb. Hippocrates.

ECHINO'PHORA, (from *εχινος*, and *φερω*, to bear). See CAUCALIS.

ECHINOPHTHA'LMIA, (from *εχινος*, a hedge hog, and *οφθαλμια*, an inflammation of the eye). AN INFLAMMATION OF THE HAIRY PART OF THE EYE LIDS; probably because the eye lid is set with hairs, as the echinus with prickles.

ECHINO'PUS, (from *εχινος*, as beset with prickles). *Crocodilion*, *acanthalruca*, *scabiosa carduiifolia*, *sphaerocephala elatior*, GLOBE THISTLE. *Echinops sphaerocephalus* Lin. Sp. Pl. 1314. It is raised in our gardens. The root and seeds are moderately diuretic, but not used.

ECHI'NUS. A HEDGE HOG; *acanthion*. In botany, those plants or parts of plants which are beset very closely with spines; or the prickly head or cover of the seed.

ECHI'NUS MARI'NUS. The SEA HEDGE HOG or URCHIN. See AMYGDALOIDES.

ECHI'TES CORYMBO'SA. See CAOUTCHOUC.

E'CHOS, (from *ηχος*, sound). See TINNITUS AURIUM.

E'CHYSIS, (from *εκχυω*, to pour out). See LIPOTHY-MIA.

ECLAMPSIA TYPHO'DES. See RAPHANIA.

ECLA'MPSIS, (from *εκλαμπω*, to shine). It is a

flashing light, or those sparklings which strike the eyes of epileptic patients. Cœlius Aurelianus calls them *circuli ignei*. Though only a symptom of the epilepsy, Hippocrates uses the term for the disease itself. Dr. Cullen places it as a synonym with epilepsy, and adds, "that Vogel and Sauvages distinguished an eclampsia as an acute disease from epilepsy, which they consider a chronic one; but as it is very difficult every where to place accurate limits between acute and chronic diseases, and as the eclampsia of Sauvages will exactly agree, for the most part, as well in the causes as symptoms, with epilepsy, I could by no means arrange it in a different genus from epilepsy."

**ECLE'CTICA MEDICI'NA**, (from *εκλεγω*, to elect). Archigenus, and some others, selected from all other sects what appeared to them to be the best and most rational; hence they were called *eclectics*, and their medicine, *eclectic medicine*. Boerhaave's system is of this kind.

**ECLE'CTOS**, **ECLE'GMA**, and **ECLEI'CTOS**, (from *λειχω*, to lick). See **LINCTUS**.

**ECLY'SIS**, (from *εκλυω*, to dissolve). An universal faintness.

**ECMA'GMA**, (from *εκμασσω*, to form together). See **CROCOMAGMA**.

**ECPEPIE'SMENOS**, (from *εκπιεζω*, to depress or press outward). An epithet for ulcers with protuberating lips.

**ECPHRA'CTICA**, (from *εκ*, and *φρασσω*, to obstruct). Deobstruent medicines.

**ECPHRA'XIS**, (from the same). An opening of the pores.

**E'CPHYAS**, (from *εκ*, and *φυνω*, to produce). An appendix, or excrescence. The *apfendicula vermiciformis* is sometimes thus called.

**ECPHYSE'SIS**, (from *εκ*, and *φυσω*, to breathe through). A quick expulsion of the air out of the lungs.

**E'CPHYSE**, (from the same,) flatus from the bladder through the urethra, and from the womb through the vagina.

**E'CPHYSIS**, (from *εκ*, and *φυνω*, to produce). See **APOPHYSIS**, also **DUODENUM**.

**ECPIE'SMA**, (from *εκ*, and *πιεζω*, to press out). **MAGMA**; or the JUICE that is pressed out from the plants of which the magma is made. It is also, with little propriety, the name of a kind of fracture of the cranium, in which the bones are shattered, and press inwardly, on the membranes of the brain.

**ECPIESMOS**, (from *εκ*, and *πιεζω*, to press out.) In general it implies expression; but it is the name of a disorder of the eye, which consists in a great prominence of the entire globe, thrust, as it were, almost out of the orbit by a flow of humours, or a tumour from the bottom or sides of the orbit.

It is also a true exophthalmia produced by strong exertions, by which the eyes are so far pressed out as to remain prominent. Protuberances of the eyes, happening from child bed pains, are often cured by the succeeding discharges and lochia. It is therefore unnecessary to employ any remedy. Wallis's *Nosologia Oculorum*.

**ECPI'PTICA**. See **ECPYEMA**.

**ECPLERO'MA**, (from *εκπλερωω*, to fill). Any substance to fill a cavity. In Hippocrates, they are hard balls of leather, or other substances, adapted to fill the

arm pits, while, by the help of the heels, placed against the balls, and pressing the same, the luxated os humeri is reduced into its place.

**ECPLE'XIS**, (from *εκπλησσω*, to terrify or astonish). A stupor or astonishment, from sudden external accidents.

**ECPNEUMATO'SIS**, **ECPNCE'A**, (from *εκ*, and *πνεω*, to breathe out). See **EXPIRATIO**.

**ECPTO'MA**, (from *εκπιπλω*, to fall out). The exclusion of the secundines; and the separation of corrupt parts. See also **LUPATIO**, **HERNIA SCROTALIS**, and **PROCIDENTIA UTERI**.

**ECPYE'MA**, (from *εκ*, and *πυνω*, to convert into pus,) the suppuration of a collection of pus, from tumour, or vomica. Medicines abounding with maturating or suppuratory powers were consequently called by Galen *εκπυκλικά*. Empyema was used by the ancients in the same diffuse sense, but the moderns confine it to a disease of the chest. See **EMPYEMA**.

**E'CPYSIS**. See **EXCRESCENTIA**.

**ECRUE'LLES**. See **SCROFULA**.

**ECRE'XIS**, (from *εκρηγνυμι*, to break). A RUPTURE. Hippocrates expresses by this term a rupture or laceration of the womb. See **HERNIA**, and **HERNIA UTERI**.

**ECRI'SIS**, (from *εκρεω*, to flow out). See **SEMEN**.

**E'CROE**, (from *εκρεω*, to flow). *Exerchesis*, or *exerchysis*. An efflux, or the course by which any fluid, which requires purging, is evacuated.

**ECRY'THMUS**, (from *εξ*, *ex*, and *ἁρμονος*, harmony). See **ARYTHMUS**.

**ECSARCO'MA**, (from *εκ*, and *σαρξ*, flesh). A FLESHY EXCRESCENCE.

**E'CSTASIS**, (from *εξισταμαι*, to be out of one's senses). An ECSTASY. It is a species of catalépsy; but in this complaint the patient recollects the ideas that passed in his mind during the paroxysm, and often what was said by those around. In Hippocrates it signifies a delirium; and Dr. Cullen ranks it as a species of apoplexy, *apoplexia mentalis*, arising from affections of the mind.

**ECSTRO'PHIUS**, (from *εκστροφω*, to invert). An epithet for any medicine that forces the internal piles beyond the sphincter.

**ECTA'SIS**, (from *εκ*, and *τεινω*, to extend). An extension of the skin, the reverse to wrinkling.

**ECTE'XIS**, (from *εκτηνω*, to liquefy, or consume). See **EMACIATIO**.

**ECTHELY'NSIS**, (from *εκθηλυνω*, to render effeminate). SOFTNESS. It is applied to the skin, bones, and flesh when lax and soft; and to bandages when not sufficiently tight.

**ECTHLI'MMA**, (from *εκθλιβω*, to dash, or press out against). An ulceration caused by pressure on the skin.

**ECTHLI'PSIS**, (from the same). ELISION or EXPRESSION. It is spoken of swelled eyes, when they dart forth sparks of light.

**E'CTHYMA**, (from *εκθυω*, to break out). See **PUSTULA**, and **CUTANEI MORBI**.

**ECTILLO'TICA**, (from *εκτιλλω*, to pull out). Medicines which consume tubercles and corns, or which assist in drawing away superfluous hairs. See **ECTYLOTICA**.

**E'CTOME**, (from *εκ*, out, and *τεμνω*, to cut). EXCISION or EXTIRPATION. See **AMPUTATIO**.

ECTOPIÆ, (from *εκ* and *τοπος*, *locus*). PROTRUSIONS, or MISPLACED PARTS. Diseases in which a part of the body is moved from its proper seat, and forms a tumour. It is the seventh order of Dr. Cullen's *locales*, in which he includes *hernia*, *prolapsus*, and *luxatio*. Synopsis Nosologiæ Method. vol. ii. p. 366.

ECTOPOCYSTICA, ISCHURIA, (from *εκτοπος*, *misplaced*, and *κυστις*, *a bladder*). A suppression of urine from a rupture or hernia of the bladder. See ISCHURIA.

ECTOMON. See HELLEBORUS NIGER.

ECTRIMMA, (from *εκτριβω*, of *τριβω*, *to rub*). AN ATTRITION OF GALLING; an ulceration of the skin about the os sacrum. Hippocrates.

ECTROPE, (from *εκτροπω*, *to divert*, *pervert*, or *invert*), any duct by which the fluids are diverted and drawn off. In P. Ægineta it is the same as

ECTROPIMUM, (from the same,) an inversion or eversion of the eye lids, so that their interior red skin becomes prominent, and the eyes exposed. When this misfortune happens in the superior eye lid, in consequence of its resemblance to a hare's eye, it is called by the Greeks *lagophthalmia*; but Galen, in his *Definit. Med.* makes *ectropium* an eversion of the eye lids in general. According to Paulus Ægineta, however, lib. vi. cap. 12, the *ectropium* is peculiar to the under eye lid, and *lagophthalmus* to the upper; but the term *lagophthalmia* is sometimes applied to the eye lid, when retracted only, without eversion.

Sometimes this disorder is unaccompanied with any other; but often an inflammation of the eye, a sarcoma, or an encanthis, attends it. When alone, it is caused by cicatrices after wounds, exulcerations, burns, and imprudent use of astringents, or from the protuberance of the internal fleshy parts. In old people a relaxation of the orbicular muscle sometimes occasions it in the lower eye lid. If the eye lid is greatly distorted or contracted, or if the disorder hath been of long continuance, a remedy is rarely to be expected.

When a cicatrix is the cause, it must be softened by a frequent application of the steams of warm water, the egg liquor mentioned in the article ANCHYLOSIS, &c. At night, proper compresses may be applied to confine the eye lids.

When a contraction of the eyelid is the cause, if emollients and compresses fail, an incision in the form of a crescent may be made at a small distance from the eye lashes, to give room for the eye lid to cover the globe: in the upper eye lid the points of the incision should be downwards, and in the under eye lid upwards. The number of incisions may be one or more, according to the degree of the contraction; if more than one are required, the second must be parallel to the first, and at a small distance from it. After the operation at the second dressing, some digestive must be applied to encourage the granulations betwixt the incisions; and slips of sticking plaster used, to keep the upper and lower eyelids close until the incisions are healed. Fungous flesh is to be treated in the usual way. If it arise from a relaxation of the orbicular muscle, relief must be attempted by spirituous and strengthening applications. If tumours in the orbit are the cause, and they are not of a cancerous kind, the cure will depend on their extirpation. Ware's Remarks on the Ophthalmia, &c. See BLEPHAROPTOSIS.

Galen, Celsus, P. Ægineta, Keckius's Dissertation on

VOL. I.

the Ectropium, Heister's Surgery, London Medical Observations and Inquiries, vol. iv. p. 371. Warner's Cases in Surgery, p. 34. and Mons. St. Yves on the Disorders of the Eyes. Bell's Surgery, vol. iii. p. 287. Wallis's Nosology of the Eyes, p. 13. White's Surgery, p. 248.

ECTRO'SIS, (from *εκτρωσω*, *to miscarry*). See ABORTUS.

ECTROTICA, and ECTYRO'TICA, (from the same). Medicines which cause miscarriage.

ECTYLO'TICA; medicines that destroy callosities. See ECTILLOTICA.

ECZE'MA, and ECZE'SMA, (from *εκζεω*, *to boil out*, or *to be hot*). See PUSTULA.

EDE'NTULUS, (from *εδ*, *without*, and *dens*, *a tooth*). WITHOUT TEETH.

E'DERA TRIFO'LIA. See TOXICODENDRON.

EDE'SSENUM PELA'RIMUM. The name of a collyrium in Ætius, containing edes or amber.

E'DRA. A FRACTURED BONE, in which, beside the fracture, there is an impression of the instrument by which it was broken.

EDULCORA'NTIA, (from *edulco*, *to make sweet*, or *purify*). Medicines supposed to correct or "sweeten" the blood; a word, which, if allowed to have any precise meaning, must be considered as similar to *alterantia*.

EDULCORA'TIO, (from the same,) SWEETENING WITH SUGAR OR HONEY; but, in chemistry, it is the rendering preparations mild, by repeated affusions of water, to separate the acids and salts, or by different combinations to sheath their acrimony. See CALCINATIO by detonation.

EFFERVESCE'NTIA, (from *effervesco*, *to grow hot*). EFFERVESCENCE. It signifies a slight degree of ebullition in liquors exposed to the necessary degree of heat. The chemists apply it to the ebullition excited by mixing an acid and alkali. It is occasionally confounded with fermentation; but fermentation is now limited to that commotion in vegetable juices which produces a vinous or an acetous liquor, and those ebullitions that are produced by the mixture of bodies are called *effervescences*.

E'FFILA. See LENTICULÆ.

EFFLORA'TIO, or EFFLORESCE'NTIA, (from *effloresco*, *to blow as a flower*). See EXANTHEMA.

EFFLU'VIA, (from *effluo*, *to flow out*). Minute particles which exhale from bodies. By these effluvia from morbid bodies, contagion is propagated. See CONTAGIO.

EFFOE'TUS, (from *ε*, and *fetus*, *without an embryo*). BARREN, CHILDLESS; and figuratively, any thing so decayed as to have lost its virtue.

EFFRACTU'RA, (from *effringo*, *to break*). A species of fracture of the cranium when the bone is broken and much depressed by a blow.

EFFUSIO, synonymous with extravasation; fluids passing into the cellular membrane, generally from rupture of the vessels, though sometimes from debility and relaxation of the exhalants.

EGE'STIO. EXCRETION; a term generally used with respect to evacuations by stool.

EJACULA'NTIA, and EJACULATO'RIA VA'SA, (from *ejaculo*, *to cast out*). The vessels which convey the seminal matter secreted in the testicles to the penis. These are the *epididymis*, and the *deferentia vasa*: the *vesiculæ seminales* are the receptacles to the semen.

ELI'AMIDES, (from *εἰλω*, to involve). See DURA MATER.

EILE'MA, (from *εἰλω*, to involve,) PAINFUL CONVOLUTIONS OF THE INTESTINES, from flatulency. (Hippocrates.) Sometimes it signifies a covering, and, according to Vogel, a fixed local pain in the intestines resembling a nail.

EILE'ON, (from *εἰλω*, to wind). See ILEUM INTESTINUM.

EILE'OS, (from the same). See ILIACA PASSIO.

EI'SBOLE, (from *εις*, into, and *βαλλω*, to cast). An INJECTION; but the term is used to express the access of a distemper, or of a particular paroxysm.

EI'SPNOË, (from *εις*, in, and *πνέω*, to breathe). See INSPIRATION.

ELA-CALLI. *Euphorbia nerifolia* Lin. Sp. Pl. 648. An East Indian shrub, whose juice is an excellent cathartic in dropsies. Raii Hist.

ELÆA'GNUS, (from *ελαιον*, oil, and *αγνος*, chaste). See MYRTUS BRABANTICA, and OLEASTER.

ELÆOME'LI, (from *ελαιον*, oil, and *μελι*, honey). In Syria this oil is prepared from the buds or the trunk of a certain tree unknown to naturalists, but probably a species of *fraxinus*: it is sweet, thicker than honey, and of a purging quality. Dios. lib. i. c. 37.

ELÆOSA'CCHARUM, (from *ελαιον*, oil, and *σακχαρ*, sugar). A MIXTURE OF ESSENTIAL OIL WITH SUGAR. The oil requires at least eight or ten times its quantity of sugar, which should be well rubbed with the mixture, and kept closely from the air. In the essential oil of vegetables reside most of the virtues that are communicated to water, or to vinous spirit by distillation; and if a proper quantity of water, or of vinous spirit be added to these *elæosacchara*, a medicine is immediately produced, of similar efficacy with distilled water, and of any given strength.

ELA'NULA. See ALUMEN.

ELA'PHICON, ELAPHOBO'SCUM, (from *ελαφος*, and *βοσκω*, to eat, because stags are fond of them). See PASTINACA SYLVESTRIS, and SISARUM.

ELAPHOPI'LA, (from *ελαφος*, a stag, and *pilus*, hair). See CERVUS.

ELAPS. A SERPENT, whose bite produces a disorder like the iliac passion.

ELAS MA'RIS. See PLUMBUM USTUM.

ELA'SIS, and ELATER, (from *ελαυνω*, to impel). See ELASTICITAS.

ELA'SMA, (from the same). A LAMINA OR PLATE OF any kind; though used to express a clyster pipe. See ENEMA.

ELASTI'CITAS, ELA'SIS, ELA'TER. ELASTICITY, (from the same). It is the property in bodies by which they restore themselves spontaneously to the figure and dimensions which they had lost by pressure or extension.

ELATE. The VAGINA, which incloses the flowers and rudiments of the great palm tree.

E'LTE THELE'IA. See ABIES.

ELATERII CORT. See THURIS CORTEX.

ELATERIUM; a word often used by Hippocrates to express an internal application of a digestive or a detergent nature. The inspissated juice of the wild cucumber. See CUCUMIS AGRESTIS.

ELATHE'RIA. See THURIS CORTEX.

ELATINE, (from *ελαυνω*, as the smaller species). *Antirrhinum elatine* Lin. Sp. Pl. 851. The leaves of this

plant are rough and bitter to the taste; and were formerly recommended internally as an antiscorbutic, and applied externally to heal old ulcers.

ELA'TINUM O'LEUM. The name of an oil in Dioscorides.

ELCOS. See CATAGMA.

ELCO'SIS, (from *ελκος*, an ulcer). Numerous, or large chronic ulcers, carious, fetid, and attended with a slow fever.

ELECTA'RIMUM, vel ELECTUARIUM, (from *eligo*, to choose, or rather *lackata*, from *laack*, Heb. to lick up, or the Greek word *λειχω*, to lick). An ELECTUARY. An electuary is of the same consistence and materials as a bolus; and where the accuracy of the dose is not essential, and a frequent change unnecessary, it is preferable to the bolus. In electuaries, when kept in the shops, medicines which will ferment or combine in new forms must be avoided. Nauseous medicines cannot be easily taken in any electuary, and, for these, pills are preferable. The latter is also the more convenient form for many metallic preparations. If electuaries are too hard, they candy; if too soft, they ferment. When soft, they are called *opiata*. The lighter powders require thrice their weight of honey, and twice the weight of common syrup; but to prevent drying too fast, a little conserve should be added. Deyeux recommends previously crystallizing the sugar in the syrup, or, at least, separating as much of it as will crystallize. The remainder will form electuaries not subject to this inconvenience, since the drying depends on the crystallization of the sugar. Treacle is not subject to this inconvenience.

Extemporaneous electuaries should not exceed two or three ounces, half of which is conserve: but this is not a fixed rule, for the consideration of how much of the medicine can conveniently be given for one dose is sometimes to be attended to; when the ingredients are unpleasant, the taste is best covered by mucilage, or a solution of liquorice juice. Mucilage is well adapted for the exhibition of powders. See Lemery's Universal Pharmacopœia.

ELECTIVE ATTRACTION, (from *eligo*, to choose, or select). This term has been usually applied to chemical affinities; but as we have employed it in physiological discussions, we shall state the foundation on which we rest.

This power is chiefly observed in the absorbent system. There is little doubt but that, on the surface, noxious vapours and noxious fluids are not taken up; and, apparently, when watery fluids are not wanted, even water is not absorbed. In many cases, when the introduction of medicines into the circulating system was thought necessary, numerous experiments were made to discover whether the chyle was impregnated with remedies given to dogs. These, though sought for at different periods, after having been taken, were seldom found. Thus we have an additional proof of the superintending power of nature to guard the constitution against injury; since, as we have had occasion to remark, the most innocuous fluids injected into the blood vessels occasion the most fatal symptoms.

How far this choice prevails we are not informed. In Dr. Alexander's experiments, bark and nitre seem to have been conveyed to the blood, as they appeared in the urine. Even at the first view, these experiments-

appear inconclusive, and other more accurate observers have not supported his opinion.

This elective power appears equally striking in the stomach and intestines. Food the most strange and singular is sometimes longed for, particularly in fevers, about, or after, their crisis; and the desire may be indulged with little injury. The mildest foods are often, by an apparently similar caprice, rejected by this organ and the intestines. In the glandular system we perceive a similar election. The fluids pass through the kidneys often in small and inefficient quantities, apparently from the presence of some medicine which they repel; for, if that is disused, the secretion returns. In this case we find all the other symptoms of a noxious matter; the functions are disturbed, the mind agitated, and fever excited. These symptoms are sometimes owing to an excess of stimulus, which, in weak organs, produces irregular action; but more frequently to the repulsion of the fluids, for where there is attraction, repulsion is also found. Why medicines affect a particular gland or injure the stomach, though innocuous in the eye, is a subject not connected with the present, and will be spoken of under the article *SECRETION*; and occasionally mentioned as a specific stimulus.

*ELE'CTIO*, (from *eligo*, to choose). *ELECTION*; that part of pharmacy which consists in a knowledge of the *materia medica*, and directs the choice of drugs, distinguishing the good from the bad.

*ELECTRICITAS*; *ELECTRICITY*, (from *ηλεκτρον*, *amber*). The quality which amber possesses of attracting light bodies when rubbed, has expanded into consequences the most extensive, and results the most important: it has become the science of electricity; has drawn thunder from the clouds; and, in the hands of philosophers, may deprive earthquakes of their destructive power. Our province is more humble: it is to trace its powers in a little microcosm, in a limited circle, where we once hoped to find it a salutary guardian; but where it appears only, if not a harmless, at least not a beneficial agent.

We must not detail the principles of this science, or enlarge on contending systems. It will simplify our language if we consider *positive* electricity as the excess, and *negative* as a deficiency, of this fluid: the former as the excess of uncombined electricity, the latter as a deprivation of the due or necessary quantity. A theory of this kind we could render equally probable with any other; but it is unnecessary, since the facts may be readily translated into a more fashionable language, if such a translation be required.

In the view we have just offered, each body has its proportionate share of this fluid, which may be increased or diminished; but, in either case, the equilibrium is only restored with some violence, called a *shock*; though it may more silently take place by appropriate means, to be afterwards described. This share is determined by the nature of the body; but is, in general, greater or less as the body is a conductor or a non-conductor; i. e. that it has a power of conducting any excess of electricity to its common reservoir, the earth, or of confining it to its own substance. Thus metals and fluids are powerful *conductors*; any dry bodies, particularly vitreous ones, *non-conductors*. The human body is, in general, a conductor, as consisting of fluids, and commu-

nicating with the earth by its surface, commonly moistened by the perspiration.

It has been rendered highly probable, by an anonymous author, in a collection of essays (*Exeter Essays*), that, on the conversion of any fluid to an aerial form, the electrical escapes; and, on the contrary, that when air is converted to a fluid, that it disappears; probably, in the first instance, separated from, and in the last combined with, the fluid. If this be true, in meteorological phenomena, as it seems to be, from a very careful induction from facts, it probably is so in physiology; and it is supported by some striking appearances. Thus the electricity of the human body, in its healthy state, is, like that of the generality of bodies, positive: such also is the electricity of the blood; but, in the animal economy, various functions continually go on, in which air is separated and carried off. The electricity, therefore, of the body must be constantly changing; and we, of course, find, as may be expected, that of some of the fluids negative. Such is the electricity of all the excrementitious fluids.

Again: We know that in confined air, in heated and crowded rooms, these aerial changes are more considerable; and it is consequently not uncommon, in such circumstances, to find the electricity of the whole body negative. Such observations have, unfortunately, not been duly examined, and we must take advantage of incidental facts. The *ignis fatuus* is, we know, inflammable air ignited by electricity. It flies from a person who pursues it, because the electricity of each is positive; but Dr. Priestley has recorded an observation, where it seemed to follow the person, who had been long in a crowded room; and we learn from Mr. Read, (*Phil. Transactions* for 1794) that the electricity of the air, in such an apartment, probably from the perspirations of a numerous assembly, is negative. We may conclude, then, that the positive electricity of the body disappears in the animal process; but nothing is lost. It, perhaps, performs a most important office, which we can only at present guess at; but this is scarcely a place for conjecture. Let us, however, at once hazard it. The electrical fluid, by its union, elicits heat (*Pictet sur le Feu*, 108); and this fluid is nearly and intimately connected with the nervous power. The one is probably occasioned, and the other supported, by the electricity that disappears.

If a resinous, as well as a vitreous, electricity exist, in other words, two fluids of different and opposite properties, the distinction appears to be immaterial in a medical view. Each produces similar effects when used as a remedy, and this consideration led us to adopt the simple language with which we introduced the subject.

Electricity is employed in medicine chiefly when accumulated. If the communication with the earth is cut off, and the fluid accumulated in the body by the action of a proper machine, it is called *simple electricity*. If then the fluid is drawn off, silently, by points, or more actively by rounded conductors, the *electric aura*, or *electric sparks*, are said to be drawn. If the accumulated electricity be at once discharged, or, in other language, if the communication between the different sides of the electrical jar be suddenly restored, the shock is said to be produced. Electricity, in each instance, acts as a stimulus only. Simple electricity increases the circulation, accelerates the jet of blood in bleeding; increases

perspiration, as well as the other secretions and the appetite. When the aura is gently drawn off, a slight stimulus augments the action of the vessels, from which it is taken; when by rounded conductors, in the form of sparks, the stimulus is more considerable. When the equilibrium is suddenly restored, every fibre seems agitated. When slight it is felt in the fingers and wrists only; when gradually more violent, the shock affects the elbows, the arms, and the chest. This happens when the equilibrium is restored, by touching the conductor with each hand; and, in this case, the fluid takes the shortest circuit, through the arms and breast, apparently passing through the nerves; for its effects are chiefly felt where they are more strictly tied down by their sheaths. When the stimulus is wanted in any particular part, the conductors are so placed as to convey the fluid necessary to restore the equilibrium through that part. The effects of the shock are said to be stimulant; but it is rather a violent concussion, without any discriminated or permanent change. It may be made so strong as to kill smaller animals; and, for a time, to deprive even a human being of his senses. When animals are killed by it, the irritability of the muscles is destroyed, an effect also occasioned by hydrogen: sometimes an important blood vessel is ruptured. If the shock be a stimulus, and destroy by excess of excitement, we might expect, that, in a less degree, it would prove useful as such. It undoubtedly excites the action of a paralysed muscle, but produces no permanent good effect; so that this mode of employing electricity is now almost wholly disused.

In general, then, electricity must be considered as a simple stimulant; and it increases all the actions going on in the system, whether salutary or morbid. It promotes suppuration, and more firmly impacts the fluids in infarcted glands. But it also discusses tumours not too firmly fixed, and assists the recovery of the nervous power of a debilitated organ.

From this view of the subject, it will be obvious that electricity is chiefly useful in asthenic diseases, and in obstructions not yet insurmountable. It must be hurtful in inflammatory disorders; where, with an inflammatory diathesis, there is a strong determination to any part; when the irritability is considerable, or the obstruction firm, and of long standing.

In *febrile diseases*, it has been seldom employed, except to terrify on the approach of intermittents; when, by the unexpected shock, it often succeeds.

In *inflammations*, it has been sometimes employed to discuss phlegmons; occasionally to relieve ophthalmiæ. In both cases the shocks are inadmissible. In the former sparks may be drawn; but, in the latter, the points must be used to solicit the aura. In the tooth ach it has been also sometimes employed, as well as in the gout and in inflammatory cynanche, but with very little effectual relief; and it is now, in general, disused.

The chief complaints in which advantage from electricity has been expected are the palsies. It was first used at Geneva; and was said to have cured a locksmith and one other person of hæmiplegiæ. It is now well known, that the relief obtained by each was temporary only; and though it continues to be employed, generally in the form of shocks, its utility is inconsiderable and temporary. In many instances it has certainly been injurious.

In the more partial palsies, drawing sparks has been occasionally beneficial, though in no considerable degree: and the power of debilitated organs, as of the eye in gutta serena; of the ear in deafness; or of a palsied muscle, has been sometimes, in part, restored. Electricity has been also tried in chronic rheumatism, a species of palsy, and in amænorrhœa. Slight shocks, in each, have been sometimes useful. In the last complaint, the fluid must be directed through the pelvis. We have sometimes succeeded in procuring a return of the menses by these means; but we have more often produced leucorrhœa. Electricity has been also often employed to restore suspended animation from apparent drowning, and is supposed to be a powerful and effectual remedy; but we have never found it of the slightest use. A physician at Brunswick, M. Friske, has directed the shocks, through the abdomen, to kill the tape worm; in which he thinks he has succeeded. On recurring to the authors on medical electricity, in almost all we observe a very prudent remark, that during its course the proper medicines are by no means to be omitted.

ELECTRO'DES, (from *ηλεκτρον*, *amber*, and *ειδος*, *likeness*). An epithet for stools which shine like amber.

ELE'CTRUM, (from *ελκω*, *to draw*, because of its attractive power. AMBER. (See SUCCINUM.) It is also a mixture of gold with a fifth part silver.

ELE'CTRUM MINERA'LE; a mass of tin and copper, with double its quantity of martial regulus of antimony, melted together. This mass, powdered and detonated with nitre and charcoal, powdered again while hot, and then digested in spirit of wine, produces a tincture of a fine red colour, accounted a deobstruent.

ELECTUA'RIVM ò SENNA. See SENNA.

ELE'GMA, (from *λειχω*, *to lick*). See LINCTUS.

ELELI'SPHACOS, (from *ελείζω*, *to distort*, and *σφακος*, *sage*), the name of a species of sage, from the appearance of its leaves and branches curling spirally: its virtues are the same with those of sage. See SALVIA.

ELEME'NTUM. ELEMENT, (quasi *elicitum*, quod omnia ex iis *elicit* sunt et extracta). A simple body, from whence any thing is first constituted, and which may be resolved into parts not of a different nature, but homogeneous. Empedocles and Aristotle acknowledged as elements, air, earth, fire, and water; an opinion now proved fallacious. Paracelsus, with other chemists, considered earth, salt, sulphur, and mercury, in the same sense; but these are allowed to be the result of theory without the support of experiment. Principles which cannot be subdivided by art are called *elements* or *first principles*; and the principles made up of these, secondary principles. Some writers carry this order much further; but it must be confessed, no means have yet been devised to show, unequivocally, whether any such subordination of principles exists. We may indeed discover the component parts of bodies, but we know nothing of their arrangement; and what are considered at one time as the simplest form of bodies, are at others found to be compounds. Hence it is said that the word ought not to be used, but as an expression denoting the last term of our analytical results. Galen observes, that the element is the smallest and most minute part of any thing whose element it is. But the word elements, in a figurative sense, is used for the principles and foundations of any art or science, as

Euclid's elements, the elements of chemistry, elements of medicine: sometimes, as in Haller's great work, the *Elementa Physiologiae*, it implies the minutest component parts; while the abstract, or rudiments, are styled "First Lines."

E'LEMI; called also *icicariba*, *icaica*, and *gum elemi*, is a dry resinous substance, brought from the East Indies and *Æthiopia*; but an inferior sort is the produce of an olive tree in the Spanish West Indies; the *amyris elemifera* Lin. Sp. Pl. 495. The elemi tree is also called *myrobalanus Zeylanicus*; *elemnifera Curassavica arbor*; *kakuria*. What is brought from the east is wrapped in flag leaves; is softish, somewhat transparent; of a pale whitish yellow colour, inclining to green; inflammable, and of an agreeable flavour when melting; to the taste bitterish; dissolving totally in rectified spirit of wine; and yielding, by distillation with water, about one ounce of essential oil from sixteen of the gum. Dr. Wright informs us that a resin, not apparently different from the elemi, is obtained from the *bursera gum-mifera* Lin. Sp. Pl. 471; the tree supposed to afford the *simarouba*. Of this resin, alcohol dissolves 0.94; and it contains also about 0.06 of essential oil.

It is chiefly used as a digestive in the form of an ointment: the London college gives the following prescription, in which it is the chief ingredient.—*Unguentum elemi*, OINTMENT OF ELEMI. Take of mutton suet prepared, two pounds; of gum elemi, one pound; of common turpentine, ten ounces. Melt the gum with the suet; and when all is quickly removed from the fire, add the turpentine; and, while the mixture is fluid, strain it.

*Arceus* was its first prescriber, and it was formerly called *linimentum vel balsamum Arcæi*. (See Lewis's *Materia Medica*. Neumann's *Chem. Works*.) When two ounces of olive oil are added, it has been called *unguentum elemi compositum*. It is the best of the terebinthinate applications for encouraging a salutary digestion in ulcers. If to half a pound of this ointment one drachm of *ærugeo æris* is added, it becomes *unguentum elemi cum æruginè*. The verdigrise must be mixed with a little oil, and gradually stirred into the ointment whilst in a melting state. This remedy has been long used as a stimulant to foul ulcers.

ELEMNI'FERA CURASSA VICA A'RBOR (from *elemi*, and *fero*, to bear). See ELEMI.

ELE'NGI. A tall tree which grows in Malabar, and bears fragrant flowers, esteemed for their cordial quality. *Mimusops elengi* Lin. Sp. Pl. 497.

ELEOSELI'NUM, (from *ελος*, a fen, and *σελινον*, parsley). See APIUM.

ELEPHA'NTIA, (from *elephas*, on account of the great enlargement of the body in this disease). ANANASARCA.

ELEPHA'NTIA A'RABUM. In Dr. Cullen's *Nosology* it is synonymous with elephantiasis. The term is, however, occasionally confined to this disease, when it affects the feet.

ELEPHIANTI'ASIS; *lazari morbus vel malum*; *Phanicus morbus*, is generally ranked as a species of leprosy (see LEPRO A'RABUM); but is distinguished from the leprosy by being seated in the flesh, while the leprosy only affects the skin, or, at the most, the integuments. This disorder receives its name from its often affecting the legs, so as to make them resemble those of

an elephant; but in many instances the legs are not affected.

Dr. Cullen places this genus of disease in the class *cachexiæ*, and order *impetiginæ*, and defines it a contagious disease, wherein the skin is thick, wrinkled, rough, and unctuous, divested of its hair; the extremities insensible, with respect to feeling; the face disfigured with hard tumours, called *tubera*; the voice hoarse and nasal. In different parts of the skin sometimes arise fungi, having the appearance of mulberries or raspberries.

Dr. Towne assures us, that negroes are very commonly the subjects of this disorder, and that it bears a great affinity to the best account we have of the lepra of the Arabians. He says those are the most subject to it, who, after severe acute fevers, long continued intermittents, or other tedious diseases, are either much exposed to the inclemency of rainy seasons, and the cold dews of the evening, or who are constrained to subsist on bad diet.

On the first attack the patient complains of shiverings; these continue a few hours, and are succeeded by a pain in the head, back, and loins; a nausea and vomiting soon follow, with pain in one of the inguinal glands (never in both): a severe fever follows; the gland reddens, becomes hard, but seldom suppurates; a red streak runs down the thigh, from the swelled gland to the leg, almost an inch broad, and of a flesh colour: this streak soon swells, and then the fever abates, and the matter is thrown upon the leg by an imperfect crisis. By degrees the leg is more and more tumefied, and the veins are formed into large varices, which are very apparent from the knee downward to the toes. Soon after, the skin grows rugged and unequal; a scaly substance soon forms on it, with fissures interspersed. These scales do not dry, but are daily protruded forward, until the leg is greatly enlarged. Though this scaly substance appear harsh and insensible, if it is very superficially touched with the point of a lancet, the blood freely oozes out. Notwithstanding the monstrous size of the diseased leg, the appetite remains good, and in all other respects the patient is healthy: many continue in this state for twenty years or more, and make no other complaint than what the enormous size of the leg occasions. It rarely happens that both legs are affected. White people suffer from this disorder when in the same circumstances which produce it in the negro. The disease is infectious, and often found to be hereditary.

The cure is uncertain: after cleansing the first passages, warm diaphoretics may be mixed with antimonials, and administered with the bark. The diet and mode of living should conduce to increase the *vis vitæ*. Mercury is said to be injurious; but experience has occasionally shown its utility, when joined with the remedies just mentioned.

Areteus describes the elephantiasis with great accuracy. Towne is particular in the account of it. See Turner also in his *Diseases of the Skin*, and Brook's *Practice of Physic*.

In the *London Medical Transactions*, vol. i. p. 23, is inserted a description of the elephantiasis, as it appears in Madeira, with the method which in one instance was attended with success. In this country the disorder appears at first in the form of tubercles on any or all parts of

the body; in time they ulcerate: if they occur on the beard or eye brows, the hairs fall off; but this does not always happen on the head. The legs swell, and are hard; white scales cover them, and fissures occasionally appear, though the legs are sometimes emaciated and full of ulcers. The *alæ nasi* are swollen and rough; the cartilage of the nose sometimes destroyed; the lobes of the ears are swollen; the voice hoarse; the nails are thick and scaly; the skin white, shining, and insensible; the breath offensive; the pulse weak and slow. Many other very disagreeable symptoms occur in different patients. None are observed to receive this disorder from others by contact; but generally the children of the diseased are subjected to it.

It usually appears here as a chronic disease on the decline of life, and every circumstance shows a great deficiency of nervous power. We never saw, in the few cases that have occurred to us, any advantage from medicine; but the bark, with the following embrocation and blistering, is said to have relieved after mercurials and antimonials had failed. The following is the mode recommended: Applicetur emplastrum epispasticum nuchæ. R. Cort. Peruv. pulv.  $\frac{3}{4}$  i ss. cort. radicis sassafræ pulv.  $\frac{3}{4}$  ss. syr. q. s. fiat. electar. cap. q. n. m. majoris bis in die.

R. Spt. vini tenuior.  $\frac{3}{4}$  viii. lixiv. tart.  $\frac{3}{4}$  i. spt. sal ammon.  $\frac{3}{4}$  ii. m. f. embrocatio qua inungantur partes affectæ mane nocteque.

The disease was, however, apparently mistaken, or the event unfaithfully related.

The cause is often indigestion, and it has been attributed, in the island of Madeira, to the poison of fish. Sometimes emetics, and in some instances cooling antiphlogistic medicines, are said to have been there serviceable. In the elephantiasis of the East (see Asiatic Researches), white arsenic is said to have succeeded. Dr. Semple advises mercury and antimony, with an embrocation consisting of eight ounces of spirit of wine, an ounce of aqua kali, with twice as much aqua ammoniæ.

**ELEPHA'NTINUM EMPL.** A plaster described in Oribasius. Celsus describes one of the same name, but very different in qualities.

**E'LEPHAS**, (from the Hebrew term, *eleph*). In chemistry it signifies *aquafortis*; in zoology, the large animal called an *elephant*; in nosology, the *elephantiasis*.

**ELERSNA.** See **MOLYBDENA**.

**EL'ETARI.** See **CARDAMOMUM**.

**EL'ETARI PRIMUM.** See **AMOMUM**.

**ELUTHE'RIA.** See **THURIS CORTEX**.

**ELEVA'TIO**, (from *elevo*, to lift up). See **SUBLIMATIO**.

**ELEVA'TOR AURI'CULÆ.** This muscle arises from the external termination of the frontal muscle, it being formed of different fleshy fibres covering the temporal muscle; and being thin and membranous, is carried over it; then growing narrower, is inserted into the upper part of the ear, bringing it upward and forward.

**ELEVA'TOR LABII INFERIO'RI.** See **LEVATOR LABII INFERIORIS**.

**ELEVA'TOR LABII SUPERIORIS.** See **LEVATOR LABII SUPERIORIS**.

**ELEVA'TOR LABIO'RUM.** See **LEVATOR COMMUNIS**.

**ELEVA'TOR NA'SI ALA'RUM.** These muscles arise

from the top of the bone of the nose near the lachrymal cavity, with a sharp and fleshy beginning, and falling down towards its sides in a triangular figure, not much unlike the Greek letter  $\Delta$ , run downwards the length of the bone, and are inserted broad and fleshy into the *alæ nasi*.

**ELEVA'TOR O'CULI**; *superbus*, *attollens*, and *rectus superior*. This muscle rises from the bottom of the socket, near the hole which gives a passage to the optic nerve; then passing over the upper part of the globe of the eye, is inserted into the superior and anterior part of the sclerotica.

**ELEVA'TOR PA'LEPBRÆ SUPERIO'RI.** See **LEVATOR PALPEBRÆ SUPERIORIS**.

**ELEVATO'RES A'NI.** See **LEVATOIRES ANI**.

**ELEVATO'RIMUM**, (from *elevo*, to lift up). An **ELEVATOR**. An instrument to raise a depression in the skull.

**ELHA'NNE A'RABUM.** See **LIGUSTRUM INDICUM**.

**ELICHRY'SUM.** **HELYCHRYSON**, (from  $\eta\lambda\iota\theta$ , the sun, and  $\chiρυς$ , gold; from their shining yellow appearance). *Goldyllocks*. It is a small, shrubby, downy plant, clothed with long very narrow leaves, producing on the tops of the branches several small round heads of bright yellow scaly flowers; a native of the southern parts of France; flowers in May and June, and holds its leaves all the winter.

**ELICHRY'SUM, COMA AUREA**, called also *linaria aurea*, *linosyris*, *virga aurea*, *conyza*, *gnaphalium luteum*, and **GERMAN GOLDBLOCKS**, *gnaphalium stæchas* Lin. Sp. Pl. 1193. It is cultivated in gardens, and flowers in May. The flowers are said to be diuretic.

**ELICHRY'SUM**, called also *chrysocoma*, *coma aurea*, **GOLDEN MAIDEN HAIR**, **GOLDEN STÆCHAS**, **GOLDEN OR YELLOW CASIDONY**, **GOLDBLOCKS**, *chrysocoma coma aurea* Lin. Sp. Pl. 1177.

The flowers, naturally dry and firm, retain their figure and glossy yellow colour for years. Both the flowers and leaves, if rubbed a little, smell strongly, and have the flavour of musk; but to the taste are warm, pungent, bitterish, and astringent. Water and rectified spirit take up their flavour in distillation and infusion. It is not much used in medicine, although it has been esteemed as astringent and tonic. See Lewis's *Materia Medica*, or Neumann's *Chemical Works*.

**ELICHRY'SUM MONTANUM.** See **GNAPHALIUM MONTANUM**; *g. dioicum* Lin. Sp. Pl. 1199.

**ELI'DRION.** Rulandus says, it is mastich; mercury; rapontic; or a mixture of silver, brass, and gold.

**ELI'GH MO'RBUS.** See **FISTULA**.

**ELIQUA'TIO**, **ELIQTION**, (from *eliquo*, to melt down,) an operation by which a more fusible substance is separated from one less fusible, by means of a heat sufficiently intense to melt the former, but not the latter. Thus, an alloy of copper and lead may be separated by applying a heat which shall melt the lead, but not the copper.

**ELITHROI'DES.** See **TESTES**.

**ELI'XIR**, (from the Arabic term *al-ecsir*, or *chemistry*, an appropriate production of the chemical art,) sometimes, according to Lemery, called *enchyloma*. An elixir is only a compound tincture.

**ELI'XIR A'LOES**, and **ELI'XIR PROPRIETA'TIS FRIULICUM**. See **ALOES**.

ELI XIR MY'RRHLE COMP. and ELI'XIR UTERI'NUM. See MYRRHA.

ELY'XIS, (from *λειχω*, to lick). See LINCTUS.

ELIXIVIATIO, (from *elixo*, to boil). ELIXIVATION; the operation by which a fixed salt is extracted from the ashes of vegetables, by an affusion of water.

E'LLEBORINE. See HELLERORUS NIGER HORTENS.

E'LLEBORUS. See HELLEBORUS.

E'LLOBOS, (from *εν*, in, and *λοβος*, a lobe). An epithet for such seeds or fruits as are in pods or lobes.

ELLY'CHNION, and E'LLYCHNIO'TOS, (from *λυχνος*, a lamp). The WICK of a LAMP or CANDLE. These were made of the papyrus, of the fruit of the ricinus, &c.; used by the ancients instead of cotton.

ELMI'NTHES, (from *ειλεω*, to involve; from their contortions). See VERMES.

ELO'DES, from *ελος*, a swamp; from the great moisture attending it). This is a species of tritæophya, or remittent fever, of the typhous kind, which usually terminates in fourteen or twenty-one days: it is epidemic, though not strikingly contagious; and from the beginning of the disease, through its course, profuse sweating attends. It differs from the sweating sickness, supposed to be peculiar to England, in its type, duration, and degree of debility.

ELO'GIUM, from ELLOGIUM, (from *εν*, and *λογος*, ratio). See RENUNCIATIO.

ELONGA'TIO, (from *elongo*, to lengthen out). See LUXATIO.

ELOPHOBO'SCUM. See CARA BRASILIENSIBUS.

E'LIT'Z. See ÆRIS FLOS.

ELUTRIA'TIO. ELUTRIATION, (from *elutro*, to decant). This is an operation performed by washing solid substances with water, stirring them well together, and hastily pouring off the water, while the lighter part remains suspended in the agitated fluid, that it may be separated from the heavier part. By this operation metallic ores are cleansed from the earth, stones, and other lighter unmetallic parts adhering to them.

ELU'VIES, (from *eluō*, to wash out). The humour discharged in a fluor albus. Pechlinus.

ELUXA'TIO. See LUXATIO.

ELYMAGRO'STIS, (from *ελεικος*, the herb panic, and *αγρωσις*, wild). See PANICUM.

E'LYMOS. The HERB PANIC, (from *ειλεω*, to involve; because its seeds are covered by an involucre).

ELYTHROI'DES or ELITHROIDES, (from *ελευτρον*, vagina, and *ειδος*, form). The tunica vaginalis of the testis. See TESTES.

ELYTROC'E'LE, (from *ελυτρον*, vagina, and *κηλη*, hernia). See HERNIA VAGINALIS.

ELY'TRON, (from *ελυω*, to involve, or cover). A covering or sheath. Hippocrates calls the membranes which involve the spinal marrow *ελυτρα*.

EMACIA'NTES, (from *emacio*, to make lean). Diseases that occasion a wasting of the whole body.

EMA'NSIO. Etmuller uses this word instead of suppressio, when speaking of suppressed menses. Emansio mensium, is the retention or absence of the menses beyond their usual period of appearing. See MENSES DEFICIENTES.

EMARGINA'TIO, (from *emargino*, to cleanse the edges,) cleansing a wound of the scurf about its edge.

EMARGINA'TUS. EMARGINATE, (from *ε*, from, and *margo*, margin,) deficient in its margin: when applied to the apex of a leaf, it signifies terminating in a notch, the margin being discontinued or broken.

EMASCULA'TUS, (from *emasculo*, to castrate). See MALAZISSATUS.

EMBA'MMA, vel BA'MMA, (from *βαπτω*, to immerge, or dip,) *aphobamma*. A sauce or pickle to dip victuals in. Mustard is a kind of embamma. It sometimes means a slight tincture, and is applied to water in which hot iron hath been quenched.

EMBA'PHION. A CRUET for containing embammass.

EMBASIS, (from *εν*, and *βαινω*, to go). See DEXAMENE.

E'MBLEG. See MYROBALANI EMBLICI.

E'MBOLE, (from *εμβαλλω*, to put in). The reduction or setting of a dislocated bone. See LUXATIO.

EMBORI'SMA. See ANEURISMA.

E'MBOTUM. A FUNNEL conveying fumes into any part of the body.

EMBRE'GMA, EMBROCA'TIO, (from *εμβρεχω*, to moisten, sprinkle, or soak in). EMBROCATION, *emfluvium*, *embroche*, and *cataclysmus*. It is an external fluid application, usually prepared of volatile and spirituous ingredients, and mostly used to relieve pains, numbness, or palsies. See LOTIO.

E'MBROCHE, (from *εμβρεχω*, to make wet). See EMBROCATION, and FOTUS.

EMBRONTE'TOS, (from *βρονη*, thunder,) thunderstruck. See APOPLECTICI.

E'MBRYO. An EMBRIO, (from *εν*, in, and *βρυω*, to bud). A CHILD IN THE WOMB; but Hippocrates confines the term to the child in its third stage, that is, before it is complete. See CONCEPTIO.

Galen remarks that the Greeks did not call the fœtus under two months old by the name of *embryon*, but named it *cuema*; but others styled it *embryon* during the whole time of its being in the womb. Homer applies the term *embryon* to the fœtus of brutes, and Theophrastus to the seeds of plants; and they are followed by all the moderns.

EMBRY'ONUM BALSAMUM vel SPT. It is a prescription of Bates; but in point of excellency is exceeded by a mixture of the spirituous aniseseed water and simple cinnamon water, in equal parts.

EMBRYOTHLA'STES, (from *εμβρυον*, a fœtus, and *θλαω*, to break). An instrument to break the bones of a fœtus, in order to its more easy delivery; or a crotchet for extracting a fœtus. See EMBRYULCIA.

EMBRYOTO'MIA. EMBRIOTOMY, from *εμβρυον*, a fœtus, and *τεμνω*, to cut). It is the division of the child while in the womb, in order to its easier delivery.

EMBRYU'LCUS. (from *εμβρυον*, a fœtus, and *ελαω*, to draw). The instrument required for artificial delivery, or *embryulcia*.

EMBRYU'LCIA, (from *εμβρυον*, a fœtus, and *ελαω*, to draw). A hook for the extraction of a child when labour is difficult. In the present practice of midwifery, as circumstances vary, the fœtus is drawn from the uterus by the blunt hook, the straight forceps, the curved forceps, or the crotchet: the latter would be fatal to the child, if alive, so that it is seldom employed

unless it is known to be dead; but its delivery is only expedited and facilitated by the other three.

The blunt hook is used when the child presents with its breech, and the pains are not sufficient for effecting its delivery. In this case the hook is carefully to be fixed in the groin of the child, and, as the pains return nature must be assisted by gently pulling with the hook; but if much strength is required, it is still better to leave the delivery to the usual assistance of the hands only with the labour pains, because the hook may dislocate or break the thigh of the child. When the hook is used, it should be taken away as soon as the finger can be fixed in the child's groin.

The crotchets are used in the same manner as the forceps, except that the crotchet, having a hook at its point, is forced into the part to which it is applied.

The straight forceps are used for bringing the head of the child forward, when, by reason of its size, or the want of pains, it cannot otherwise be protruded; but much care should be taken in using them. They are never to be employed while the head is above the brim of the pelvis, and indeed very rarely when it has descended lower. Dr. Hunter absolutely forbids their use, if they can possibly be avoided, consistently with the safety of the child; for, if time is allowed, the parts will dilate, and the head will be moulded so as to pass with the least possible violence.

The forceps, as improved by Smellie, are the best; he reduced their length, to prevent their being used before the head is sufficiently low. They should not be applied before the ears can be felt, and previous to their use the following rules should be observed:

1. The external parts should be sufficiently dilated.
2. The exact situation of the child's head should be known; and this is best discovered by feeling one ear.
3. A finger should be in the os internum to guide the forceps, lest a part of the uterus itself should be included in them. When the finger cannot be thus introduced, great care is required in passing the forceps along the side of the child's head.
4. The blades of the forceps should be well greased before they are introduced.
5. If possible, apply the blades over the child's ears; for thus they are placed on the narrowest part of the head; when this cannot be done, fix one before one ear, and the other behind the opposite one.
6. The forceps should be passed up in the direction of a line that may be supposed to pass through betwixt the navel and the scrobiculus cordis; at the same time keeping the handles as far back as the perinæum will easily admit. When the forceps are secure, pull them from blade to blade; for otherwise they are apt to slip off.
7. The handles should be tied tight before the operator begins to pull downwards with them; and when the two blades are locked, the lock should be about an inch from the child's head.
8. As the child's head advances, the operator should alternately rest and pull while the perinæum is on the stretch, and until the vertex is brought from under the os pubis; then the handles of the forceps being gradually raised towards the mother's belly, and the pulling repeated with caution, whilst with one hand the peri-

næum is supported, the forehead will be freed from it. The forceps are now to be taken away, and the delivery finished, as is usual, with the hands alone.

The different cases in which these forceps are required may be seen under the article PRÆSENTATIO.

The long curved forceps were invented by Smellie, with a view to save the life of the child, when, the body being delivered, the head could not be brought away in the usual manner. In this case the crotchet was formerly used. These forceps are longer than the straight ones, because they are applied when the head of the child is above the brim of the pelvis; but as it can very rarely happen that where the buttocks have passed (especially when doubled, as in breech presentations) the head will be detained, these instruments are scarcely ever necessary. Indeed, when the head is separated from the body, and left in the uterus, if the pelvis be much distorted, the long curved forceps may sometimes be preferable to the straight ones; but in this case, if the size of the head is lessened by emptying it of part of the brain, the delivery may generally be effected by one hand and one blade of a crotchet. Notwithstanding the advantages proposed by the use of the foregoing instruments, in some cases they are unavailing: it is then advised to open the head by the use of a large pair of scissors, with a stop put on the outward edge of each blade, about the middle; the inner edges of which are blunted downwards. These contrivances are, first, to stop the scissors before they are expanded in a proper situation, and to prevent cutting the vagina or uterus, in occasionally closing them. See PRÆSENTATIO, cases where the head presents, which will show the utility of these instruments more clearly. See the figures of these instruments represented in plate 5 of Midwifery, No. 3, 4, 5, 6, 7, 15.

EMBULA. A PIPE.

EMBULA'RCHI SUFFUMI'GIUM. A SUFFUMIGATION, described by Ætius.

E'MERUS, also *colutea*, *scorpioides major*, and *senæ*, *scorpium*, *colutea humilis*, *colutea scorpioides humilis*, *colutea siliquosa minor*, *coronilla montana*, and LESSER SCORPION SENA; *coronilla emerus* Lin. Sp. Pl. 1046. It grows on hilly places; its leaves are cathartic, and poor people sometimes gather and use them for that purpose.

E'MERUS AMERICA'NUS. See INDICUM.

EME'SIA, EME'SMA, and EME'TOS, (from *εμεω*, to vomit). The action of VOMITING.

EME'TICA, EMETICS, (from *εμεω*, to vomit,) *anacathartica*, and *vomitória*; medicines which excite vomiting.

The use of these medicines is so extensive, and their effects often so important, that they will justify our considering them at some length. The most simple view we can take of emetics is, that they evacuate the stomach by the inverted action of its own motions with those of the œsophagus, assisted by the contraction of the diaphragm and abdominal muscles. This alone is an object of no little importance when we consider the extensive influence of this organ, and the very dangerous consequences which arise from its acrimonious or vitiated contents. But the advantages do not rest here. The same inverted motion is communicated to the duodenum, and, in some degree, to the inferior parts of the

canal. Into this second stomach, as we have described it, the bile and pancreatic juice are poured; and, while the joint action of the diaphragm and the abdominal muscles compress the gall bladder to evacuate its contents, the inverted motion of the duodenum and stomach evacuate it. Emetics, in this way, unite with cathartics in assisting the secretion and discharge of bile; in relieving or preventing infarctions of the liver: for, while the latter promote the secretion by stimulating the ducts, the former contribute to the same purpose by an action more strictly mechanical.

We have often had occasion to remark the extensive influence of the stomach in the animal economy, particularly its connexion with the state of the brain and the extreme vessels. The first effect of emetics, in consequence of this connexion, is to produce a general relaxation, approaching sometimes to faintness. In this state the extreme vessels sympathise and yield, with little resistance, to the force of the circulation. Perspiration follows, which by the action of vomiting is still further increased; and, if this is kept up by other means, the most salutary changes are often produced. We perceive the connexion of the stomach with the head, rather in the morbid than the salutary effects. During the action of vomiting, the return of the blood from the head is impeded, and all its vessels are distended; which has occasioned some hesitation in the use of emetics, when these vessels were previously distended, as in apoplexy and palsy. In such circumstances, however, we find the irritation on the brain communicated to the stomach, and vomiting excited.

The agitation of vomiting has been considered as useful; but this is a vague, indistinct indication. Medicines of this kind have, however, been employed where obstructions have been suspected; and, in the brain, the alternate filling and emptying their vessels may contribute to excite and support their action. We see some traces of such an influence from their utility in nervous diseases, particularly in those attended with general languor, as hypochondriasis, and in obstructed menses; but more strikingly in the good effects of very active emetics, particularly of vitriolated mercury in the cure of gutta serena. Another distant effect of emetics is more certain: their increasing the action of the absorbent system. Their operation, in this way, is not easily explained, but such effects are well established; and, on this account, we shall find them extremely serviceable, when we wish to promote the absorption of purulent matter that we cannot with ease or safety evacuate. They cannot be employed to relieve the more extensive accumulations of dropsies.

A very important effect of emetics, referrible in part to their action, and sometimes, perhaps, to the nature of the medicine, is their power of emulging the bronchial glands. On the first access of nausea, we find a flow of saliva, and a little discharge from the bronchiæ; but, when the emetic begins to act with some violence, this discharge is considerable; and no remedy is more powerful in producing a complete evacuation of those glands, or relieving them from the infarctions of viscid mucus. In part, this effect may be owing to the medicine; for we shall find some of the most active emetics to be expectorants also.

Emetics are of very different kinds. Some are purely

stimulant, as mustard, volatile alkali, and horse radish root. Others are sedative or relaxant. Opium, in large doses, acts as an emetic. Foxglove, tobacco, putrid substances, oil, and warm water, are emetics of different strength, nearly in their order. The greater number, however, act apparently by a peculiar stimulus. In some of these the stimulus is obvious; and, when the stomach is not affected, acts on other secretory organs. The principal emetics of this kind are the antimonial preparations, which affect the bowels, the skin, and sometimes the bronchial glands. The mercurials are similar in this respect; but the copper, zinc, and platina, which in all their forms are emetic, seem not to affect any other glands. The acrimony of the squill and the seneka root is very general: they are not only emetics, but cathartics and expectorants. The asarabacca and the groundsel juice are more limited in their stimulant powers. The former, besides its emetic property, acts chiefly as an errhine, and the latter only on the intestines. The ipecacuanha is the connecting link between these more general stimulants and medicines, which seem to act from a specific influence on the stomach. There are certainly emetics which may be referred to this head. The vitriols of zinc, already mentioned, not to separate the metallic substances, have little general stimulus; and the air of the lungs which, when swallowed, proves certainly emetic, is wholly without any other power. Every nauseous taste tends to excite the action of the stomach; and to this head may be referred the bitters, as wormwood, camomile flowers, the seeds of the carduus benedictus and broom. Putrid substances, and the liver of sulphur, act apparently in the same way.

Other causes of vomiting are more obscure in their action. Association of ideas is a mental operation; yet a very frequent and certain cause of vomiting is, the recollection of objects connected with the evacuation of the stomach at a former period. Motion in a circle, in a ship, or in an unaccustomed direction, has the same effect. The motion of a wheel carriage, especially if the windows are closed, or the person sits in the back seat of a coach, will often produce vomiting. This effect, as connected with the changes in the common sensorium, must remain in obscurity.

The principle on which emetics act is not readily explained. It has been said that they are constantly sedatives; and, as plausibly, that they are always stimulant. Very powerful emetics belong to each class, yet, perhaps, a different principle influences their operation. The affection of the stomach is apparently increased action; but, in medicine, increased action is sometimes owing to a defect. It is, more obviously, irregular action; and we might thus attribute vomiting to the principle we have already endeavoured to establish, that irregular action is connected with a diminution of tone. We certainly, in this way, approach, at least, very near the truth; and the facts will in general support it. In every instance, however, except where vomiting is owing to an affection of the brain, there appears to be a substance inimical to the constitution, which the stomach, influenced by the vires medicatrices, attempts to discharge; and the necessary motions are consequently excited. Yet we must keep in our view, that languor and faintness, from any cause, will produce the

same effect; and we thus see why causes of extreme debility will equally excite this organ, independent even of the presence of any medicine, certainly by the intervention of any violent commotion. In this way may, probably, be explained the experiments of those who have excited vomiting by injections of emetic medicines into the veins. In fact, every foreign substance in the blood vessels excites such commotions, with faintings and convulsions; nor is it surprising that the stomach should equally suffer. In general, then, the most active emetics are the most powerful sedatives; and the whole class of poisons, particularly the narcotic cathartics, are violently emetic.

The motions of the stomach during the operation of emetics are, as we have said, inverted. This has been proved by ocular observation; and it is equally certain, that the action of the muscular fibres of the œsophagus is equally inverted. A nauseous draught, the repetition of an emetic, will sometimes excite the action of the œsophagus only; and we once saw it so permanently excited by a crystal of emetic tartar sticking in it, that the mildest fluids could not, for a long time, pass into the stomach. The action of the fibres of the stomach surrounding the cardia is, in some instances, exclusively excited: as in those who discharge wind, a small portion of acid, of oil, or any substance swimming on the surface of the contents of the stomach, and producing cardialgia. The more violent exertions of this organ alone discharge its whole contents; and such exertions must be strong and long continued before they are communicated to the duodenum. These are not facts merely of curiosity, but of great importance in the exhibition of vomits. It is in vain to expect benefit from them, if only the slight ineffectual discharge of a little of the tea, which has been drunk, takes place. The strain, such as arises from the action of the greater curvature, is necessary, if any viscid mucus is to be evacuated; if any effect on the liver can be expected. The evacuation of bile appears towards the end of the operation, sometimes after the interval of two or three hours; frequently on taking in the first draught of negus, or a similar cordial. The expediency of the remedy is then triumphantly pointed out; but, in reality, the bile was the effect, and was not previously in the stomach. The assisting actions of the diaphragm and abdominal viscera are sufficiently felt during the operation, if the facts were not ascertained by the experiments of Mr. Haighton.

These observations are of some importance in the administration of emetics. If the medicine is not for some time in the stomach previous to the vomiting, the whole organ is seldom excited. It has been usual to direct that the emetic shall be first discharged, probably from its apprehension of doing some injury. The practice is, however, proper, from its thus exciting every portion; but, as the vomiting, without some contents, is painful, on the first appearance of sickness a little camomile tea may be allowed. In the whole operation, however, if more than a half pint of any fluid is contained in the stomach at one time, the greater is the probability of its acting incompletely. In cases of poisons the vomiting is extremely violent, and we then only want to dilute, and to render the action as easy as is consistent with the discharge. The dry

vomits, as they are called, where all drinking is precluded, are painful remedies, but of great importance in assisting the bronchial discharges, or in relieving visceral obstructions.

Opposed to the severity of dry vomits, are the milder nauseating doses of antimonial or squills. These assist, in some degree, the discharge from the bronchiæ, but not so effectually as full vomiting. Their chief advantages are in the earlier state of fevers; in which they, in some degree, contribute to relieve the dryness of the skin, and to mitigate, by this effect, the great heat.

The use of emetics is very extensive. In *fevers* of every kind they are most powerful remedies. In *intermittents*, the vomiting, sometimes excited on the accession by nature, has taught us to lessen the violence of the paroxysm by emetics; and occasionally to prevent it, by their previous exhibition, and continuing to support the perspiration they excite. In every intermittent, and remittents also, we find bilious congestions, which active vomiting contributes to relieve. By this means the paroxysms of each gradually become milder; and there have been many instances where no other remedy was required.

In *continued fevers* emetics are highly useful, but their effects are not equally striking. The debilitating power of every febrile attack affects the stomach, and produces those irregularities of the digestive process which we have already described. The wholesome aliment is, in this way, converted into an injurious load; and emetics are not more useful in determining to the skin, than in removing the acrimonious or putrid saburræ. When contagion also has been received, though breathed with the air, it immediately affects the stomach, producing a bad taste in the mouth. This, with all the subsequent bad consequences, an emetic, followed by a brisk cathartic, will often remove. The particular kinds of fever offer few remarks of importance. In the synocha, bleeding, if it be at all admissible, should be premised; but the young practitioner, eager with his lancet, should reflect, that every throbbing pulse is not a strong one; nor does every headach portend approaching delirium. Emetics have often been of service even in the most inflammatory fevers, when bleeding has not preceded; and we should always consider, that the most putrid fevers are sometimes ushered in by symptoms seemingly inflammatory. In the lower putrid fevers, emetics are useful; but the nauseating doses, which may be continued in inflammatory fever, should soon be omitted in the latter, as they debilitate in a considerable degree.

In the next order, the *phlegmasiæ*, emetics are less essentially necessary; and, in these, bleeding must be frequently premised. After vomiting, the nauseating doses may be continued with the best effects. In the *pneumonia* they are often important remedies, from their power of emulging the bronchial glands. In *phrenitis*, though dangerous from increasing the accumulation in the head, we are sometimes obliged to employ them. In *cynanche* they are inconvenient, though useful, remedies. When the inflammation terminates in suppuration, suffocation often impends, and then vomiting, a precarious remedy, which may even bring on the fate it is intended to avert, may at once rescue the victim from the grave. Firm and steady must be the physician

who prescribes it; but he who would for a moment hesitate when his patient's life is at stake, whatever risk he may personally run, merits not the name of man, nor the character of a physician. In the other pyrexia we find little room for the use of this remedy. In *hepatitis*, for obvious reasons, it is doubtful, though sometimes useful; in *enteritis* the natural vomiting is often the most troublesome symptom; but in the *peritonitis puerperarum*, emetics, given early, have been considered as a most certain remedy. It would give us the greatest satisfaction could we confirm these assertions. On trial we have, however, found them useful. In *gout*, emetics have been employed to obviate the return of paroxysms; and in *rheumatism*, if bark be useful in this view, vomits must be equally so.

If the explanation we have offered of febrile cutaneous diseases be correct, emetics must be a remedy of peculiar value and importance in the order *exanthematosa*. We need not enlarge on the different kinds, for in each these remedies are useful on the first appearance of fever. In those, however, attended with nervous or putrid fever, the repetition must be attempted with caution.

In *hæmorrhages*, emetics are supposed of doubtful efficacy; but they are more generally useful than has been supposed. With respect to the *hæmorrhagia cerebri* we shall reserve our observations for the present; and in *epistaxis* we need not have recourse to an active, uncertain remedy, when we have more safe ones within our reach. In *hæmoptysis*, emetics have been forbidden; but with little reason. Dr. Robinson, near sixty years since, recommended them as safe and effectual remedies; and we know that there are none which more certainly deserve this character: yet the general opinion is so decidedly in opposition to their employment, that, unless in emergency, we think they should not be exhibited; or even in *emergency* not professedly as emetics. One of the most obstinate hæmoptyses the author of this article ever saw, yielded only to the digitalis, which acted as a violent emetic; and its action was continued for several days. The bleeding only ceased during the operation of vomiting, and was finally stopped. Vomiting has been employed with success in *mænorragia*; but a physician may brave popular prejudice more safely in any disease than in female ones: nor is their utility in this complaint very clearly established. We speak, however, only at present of febrile mænorragia. In every other kind, emetics are decidedly injurious.

Of the *profluvia*, the only genera, *catarrh*, and *dysentery*, are greatly benefited by these remedies; nor can we add to what we have already remarked respecting their utility, or offer any observations to limit their employment.

The order *neuroses* offers abundant subject of discussion, was this a place for extensive inquiries; and had we not, in part, anticipated every essential remark. It will be at once obvious, that we refer to apoplexy and palsy, and the disputes which have arisen on the subject. In our former article (see *Apoplexia*) we gave the result of our observations; and then remarked that, though we had been ourselves cautious in the exhibition of emetics, we had seen them employed by others without injury; adding, that their inconveniences were slight and transitory, their good effects consider-

able and permanent. To this we may now subjoin what has since occurred in the progress of our work, that the venous system of the brain is apparently calculated to admit of distention, without any essential injury. The coats of many of the sinuses, particularly those at the base of the brain, admit easily of distention, are tortuous, and anastomose freely. On the whole, then, though we must consider emetics as remedies somewhat precarious, we think that they ought to be employed in such circumstances; and on taxing, most impartially, our recollection, we cannot find that, in a single instance, in our hands, or those of others, they have been hurtful. On the contrary, we have very often found them beneficial.

In the *adynamia*, emetics are of very extensive utility. They are of doubtful efficacy in *syncope*, when the disease arises from a topical affection of the heart and larger arteries, or when owing to debility, or an exhausted constitution. In many, perhaps the greater number of instances, fainting proceeds from accumulations in the stomach, and emetics are then absolutely necessary. In *dyspepsia*, *hypochondriasis*, and *chlorosis*, they are remedies of the greatest importance.

The order styled *spasmi* is a group of diseases scarcely connected. *Palpitatio*, however, like syncope, more commonly depends on accumulations in the stomach and bowels than on any other cause; and *asthma*, with *dyspnea*, as we have seen, is greatly relieved by the operation of emetics, when not owing to any topical affection of the heart and arteries. If any medicine be useful in *pertussis*, it is occasional vomiting; but the *pyrosis* is a spasmodic complaint, and ultimately cured by a very different plan. Emetics are often useful as temporary palliatives. In *colica*, in *cholera*, and *diarrhæa*, we have had occasion to point out their utility; but in *hysteria*, though sometimes necessary, they are of doubtful efficacy. In the other genera they are not employed, or only occasionally useful.

In the *vesania*, emetics are the most important remedies. When the disease is not connected with the stomach, which generally happens, they are probably useful by the agitation formerly mentioned among their effects.

In the first order of the *cachexia*, the *marcores*, we find little foundation for their employment; yet, as in *tubercles* the hectic fever is mentioned, they may appear to be indicated. But the fever, in this case, is from debility only, the exacerbation of the common evening paroxysm. It reminds us, however, of an omission, which we must supply, the utility of emetics in *phthisis*; a disease that has no appropriate place in the system of Dr. Cullen, which we have chiefly followed. Whether we consider the fever as a remittent, the bronchial glands as infarcted, or the existence of purulent matter in a concealed abscess, emetics appear to be medicines of the greatest utility. In fact, they are so; and could phthisis be ever cured, it would be by the joint action of emetics and blisters. No remedy is so generally useful as a slight emetic, frequently repeated; it checks the fever, relieves the burning heat, renders the respiration more free, and the cough more loose. Yet hæret, lateri lethalis arundo, emetics will not cure. In *dropsies* we have mentioned the occasional utility of natural vomiting, and stated that we have not yet been able to imitate it by art; but in *hydrocephalus* and

*hydrothorax* it is inadmissible. We find a few solitary cases where the water in *hydrocele*, a partial dropsy, has been evacuated in this way.

For the various genera of the order *impetigenes* we find little room for the use of this remedy. If *frambæsia*, as Dr. Adams thinks (Memoirs of the Medical Society, vol. vi.), be an exanthema, emetics may be of service, as they very certainly are in *icterus*. Even where the pain at the pit of the stomach is violent, and the existence of a calculus unequivocal, though emetics may for a time increase the pain, the relaxation which they produce assists its passage. Neither in accidental nor in artificial vomiting have we ever found, in this case, any inflammation (the great source of alarm) follow. Emetics are of more importance in the last class of diseases, than from their *local* nature might be expected. In every case of obstructed sense, where the cause is not so firmly fixed as to resist every power, these remedies are useful; in the *caligo* for instance, *amaurosis*, *dysæcia*, and *ageusia*; in the greater number of depraved and deficient appetites; and in some of the depraved or irregular motions. In the *apoceneses*, the passive hæmorrhages, or mucous discharges, they are certainly injurious. In the *epischeses*, if we except the *amenorrhæa*, and in the *tumores*, except the purulent ones, they are hurtful.

The choice of emetics is a subject of some importance; but it is chiefly regulated by the quickness or the violence of their action. The most quickly operating emetic, in cases of emergency, is the white vitriol; the most violent is the turbitim mineral. It is common to select the mercurial emetics in venereal cases; but this plan is not attended with peculiar advantages. We have often thought it singular that the squills are not more frequently employed for this purpose in asthma or pneumonia. They indeed produce a very permanent and distressing nausea, and are often employed as nauseating remedies; but we suspect that they might be particularly useful if given in these cases so as to produce full vomiting. In such instances physicians seem to prefer the antimonial emetics, and it must be allowed that the squills are very uncertain in their operation.

Emetics are injurious when there is any original defect in the head, in the heart and larger arteries, or, perhaps, in the abdominal viscera, if we except the liver; in the aneurisms of the larger vessels, in the delicate and the weak, if particularly plethoric. If no plethora exists, debility is seldom so considerable as to contraindicate vomiting, should there be any foundation for thinking it may produce real good effect.

With respect to the administration, we have little to add to what we have already remarked. In cases of fever we prefer the evening; in asthmatic cases, the morning; in hectic, the period when the febrile accession is most strongly marked. In the other disorders there is little choice of time. The preferable form is a liquid; and were the preparation of the ipecacuanha wine to be always depended on, this would be the best form of a medicine almost universally employed as an emetic, since the powder, apparently entangled in the coats of the stomach, sometimes occasions a continuance of painful retchings. Those who have repeatedly taken this medicine often find even the smell or taste sufficient to excite vomiting; and, from what has been said, it will be obvious that such vomiting will be ineffectual.

To patients of this class it may be given in pills, or the tartarised antimony may be substituted.

Vomits, taken in the morning, should be allowed to produce their operation in bed. In the evening, if not taken in bed, the patient should immediately retire to it, without exposing himself to any chill. At any other period of the day, cold, after the vomiting, should be carefully avoided.

Any warm liquid may be employed to facilitate the action of the emetic; but the camomile, the carduus tea, mustard infusion, or whey, or the volatile alkali added to the bitter infusions, greatly facilitate it.

**EMETICUM MITE.** The mild emetic of Boerhaave is made by deflagrating one part of crude antimony with two of nitre. By this process all the sulphur is consumed, and a large proportion of oxygen combined with the metal, which reduces it to the state of an inert earth; it is therefore, in every sense, mild.

**EMETICUM VINUM.** See **ANTIMONIALE VINUM.**

**EMETOCATHARTICUM**, (from *εμεω*, and *καθαίρω*). A medicine which operates both by vomit and stool.

**EMISSARIUM**, (from *emitto*, to send forth). An **EMISSARY**. In medicine it is any outlet, whether natural or morbid, from which any thing is discharged.

**EMMENAGO'GA**, **EMMENAGOGUES**, (from *εμμηνα*, the menstrual discharges, and *αγω*, to propel,) *menagoga*; medicines suited to promote the menstrual flux in women; or to excite and restore it when retained or suppressed.

The establishment of this class has occasioned much hypercriticism; yet, as pointing out a change to be produced, it is equally proper with emetics or cathartics; nor is it an objection that we must produce the change through some medium, and not by any direct action on the vessels themselves.

Emmenagogues are general or partial stimulants, tonics, or antispasmodics. We cannot, however, enlarge on their utility or application, while the cause of the discharge itself has not been investigated. We are compelled, therefore, to defer the consideration to a future part of the work, and trust then to be able to give a comprehensive account of the whole subject: we shall endeavour to give a satisfactory one. See **MENSES.**

**EMME'NIA**, (from *μην*, a month). See **MENSES.**

**EMMO'TOS**, (from *μοτος*, lint). An epithet for persons, parts of the body, or disorders, that require lint for the cure.

**EMO'DIA**, (from *εν*, and *οδους*, dens). A **STUPOR OF THE TEETH.**

**EMOLLIE'NTIA**, (from *emollio*, to soften). **EMOLLIENTS**, *malacticos*. Medicines which lessen the force of cohesion in our simple solids, and therefore soften and diminish the hardness and rigidity of the parts to which they are applied. They not only relax the solids, but also sheath and defend them from the acrimony of the fluids. When externally applied, they are termed *emollientia*; internally administered, *demulcentia*. (See **DEMULCENTIA.**) Dr. Cullen thinks that emollients act upon the parts to which they are immediately applied, either by insinuating themselves into the substance of the solid, and diminishing the density and force of cohesion of the mixt; or, by being insinuated

into the interstices of dry particles, they diminish the friction that might otherwise occur, and thereby render the whole more flexible.

We have not, however, the slightest evidence that any permanent change can be made in the mixt, by the temporary application of oil or warm water. The nervous system is relaxed by warmth, and the simple solids partake of the change; but it is temporary only. A permanent change is only produced by a warm climate, or some relaxing occupation. In the simple solids we only find a greater flexibility, in consequence of emollients, which in Dr. Cullen's system appears to be correctly explained.

Emollient topics are formed of water, oily and mucilaginous substances. Water, particularly when assisted by a moderate heat, is plentifully absorbed from the whole surface of the body. It powerfully relaxes and dilutes, being miscible, though it does not enter into the composition of the solid, with almost every animal fluid. Oil relaxes and obtunds what is rigid and acrimonious; and mucilage equally sheaths sharp humours. In compositions of this kind, the aqueous part should be freely admitted, for the mucilages require to be largely diluted; gentle friction on the part increases their efficacy, by promoting the circulation; but the heat with which they are applied should not exceed what produces a pleasing sensation. From the relaxing and demulcent quality of emollient topics, they are useful sedative applications, when pain from tension, or from irritation, is excited: from the sympathy of the nerves, their efficacy is conveyed to distant and deep seated parts; and thus the warm bath proves so powerful a sedative. From the same principles these applications are also antispasmodics. Emollients, by relaxing the fibres, and promoting the circulation, hasten suppuration. See Aikin's Observations on the external Use of Preparations of Lead, p. 29, &c.

EMO'TIO, (from *emoveo*, to move out). When used with respect to the mind it signifies a delirium; when relative to some bone, a luxation.

EMPA'LEMENT. See CALYX.

EMPA'SMA, (from *πασσω*, to sprinkle upon). See CATAPASMA.

EMPE'ROS, (from *εμπερω*, to mutilate). MUTILATED.

E'MPETRUM, (from *εν*, and *πετρος*, a stone). See ALYPUM.

E'MPETRUM THYMELÆ'Æ FO'LIIS, also called *sanamunda*, and SEA HEATH SPURGE; *daphne thymelæa* Lin. Sp. Pl. 509; grows on the coast of Andalusia, and flowers in February. A drachm of the root purges violently. About Gibraltar it is called *burhalaga*; but only used to heat ovens.

EMPHRA'CTICA, (from *εμφρασσω*, to obstruct). Such topical applications as obstruct the pores when applied to the skin; also named *emplastica*, *emflatomena*.

EMPHRA'GMA, (from *εμφρασσω*, to obstruct). An IMPEDIMENT OR OBSTRUCTION; the parts of a child which present in an unnatural posture, and obstruct the birth. Hippocrates.

EMPHYSEMA, (from *εμφυσω*, to inflate,) *inflatio*; and sometimes *leucophlegmatia*; is any flatulent tumour; but it means generally a soft tumour arising from air being admitted into the cellular membrane. In Hippocrates it signifies an inflation of the belly, and some-

times a tumour in general. When ruptures or tumours are of the flatulent kind, they are called *physocèle*. Dr. Cullen means by the word *pneumatosis*, which is his general name for this disease, the swelling formed by air, a flatus, or rarefied fluids. He places it in the class *cachexiæ* and order *intumescentiæ*, and defines it, a tense, elastic tumour of the body, making, on pressure under the hand, a crackling noise. The species are, 1. *Pneumatosis spontanea*, when it happens without manifest cause; 2. *Pneumatosis traumatica*, when from a wound in the thorax; 3. *Pneumatosis venenata*, when from the swallowing or external application of poison; 4. *Pneumatosis hysterica*, when accompanied with hysterics.

The most frequent cause of this disorder is the piercing of the plura by a sharp pointed instrument, or wounding the lungs by the pointed fragments of broken ribs; though it sometimes happens that an emphysema is produced by internal lacerations of the air vessels of the lungs, without any injury to the pleura. Putridity separates air both in vegetable and animal substances; and, consequently, emphysema is the consequence of mortifications, and sometimes attends putrid fevers. It more seldom happens from pointed instruments than might be expected, as the blood instantly stops the passage.

An emphysema is known by a soft puffy swelling: the skin appears glossy, the tumour gives way on pressure, but it instantly returns; a crackling is perceived on pressing the emphysematous tumour. When the lungs are wounded, a troublesome cough attends, and the matter expectorated is mixed with blood; sometimes air escapes from the lungs into the cavity of the pleura, and occasions great difficulty of breathing, anxiety, a sense of suffocation, stupor, a livid colour in the face, and, if relief is not speedily obtained, death. The air detained in any part of the cellular membrane may produce a mortification in it.

When these tumours occur in putrid disorders, fomentations may be applied, made with equal parts of sharp vinegar and rectified spirit of wine; but when a wound is the cause, if the breathing is quick and laborious, blood must be taken, and the operation repeated as often as this symptom renders it necessary. Punctures, or rather small incisions, may be made into the cellular membrane with a lancet, or in different parts of the body; the air will thus be evacuated, if gentle pressure is also made on the tumour: after its evacuation, a compress may be dipped in vinegar, and applied over the part where the wound is supposed to be, secured by a tight bandage; and the patient should be directed to lie on the injured side, to prevent a fresh afflux of air. Nitre, and pectoral emulsions, may be given to prevent internal suppuration. When the air is detained in the cavity of the breast, Mr. Hewson proposes to discharge it by a small opening made with a knife on the fore part of the chest, which, if on the right side, must be between the fifth and sixth ribs, because there the integuments are thin: but if on the left side, the opening must be betwixt the seventh and eighth, or betwixt the eighth and ninth ribs; the better to avoid wounding the pericardium. See Le Dran's Observations, N° 29; James's Medical Dictionary, art. *Fractura*; and London Medical Observations and Inquiries, vol. ii. p. 17, vol. iii. p. 28—36, 372—399; White's Surgery, p. 78.

EMPIRICA SE'CTA, (from *ειρα*, and *πειρα*, *experientia*). The EMPIRIC SECT. It was begun by Serapion of Alexandria, or by Heracleon, about 278 years before the birth of Christ. The empyrical physicians conducted themselves wholly by experience, without study or theory, like the quacks of the present day. See Celsus de Medicinâ, p. 3, 8, 8vo. Lugd. Bat. 1746.

EMPIRICUS. An EMPIRIC, (from *πειραω*, to *experience*, or *εμπειραω*, to *try*;) an epithet applied to practitioners who founded their practice on experience only, or rather on incontrovertible facts, totally freed from all speculative ideas. In a bad sense, it is an appellation bestowed on quacks, who, without knowledge, pretend to perform miracles by some desperate nostrum; careless of the destruction they create, and eager only to pillage their unfortunate patients, generally at the expense of their health, and too often of their lives. For the difference between the empiric and dogmatist, see Percival's Essays, Medical and Experimental, vol. i.; which is, however, nearly a copy of one of Dr. Cullen's early introductory lectures.

EMPLA'STICA, (from *εμπλασσω*, to *spread upon*). See EMPRACTICA.

EMPLA'STRUM. (from the same). PLASTER. Plasters are compositions for external use: they are not always applied for any medical virtue; but chiefly used to retain other dressings, or to keep the parts to which they are applied warm and tight. These effects they produce more equally and steadily than a bandage of linen, especially if there be no swelling. They are composed of oily and unctuous substances, united with powders, into such a consistence, that the compound may remain firm in the cold without sticking to the fingers; that it may be soft and pliable in a gentle heat; and that, by the warmth of the human body, it may be so tenacious as readily to adhere. When a plaster is softened to the consistence of warm wax, it is called *cerate*; though the term is generally confined at present to such plasters as contain wax in their composition: when so soft as to spread easily whilst cold, yet not to run with the heat of the body, an *ointment*; and if betwixt the consistence of an ointment and oil, a *liniment*.

Calces of lead boiled with expressed oils unite into a plaster of a good consistence, and are a proper basis for several other plasters. Plasters may also be made of resins, gummy resins, &c. without wax, especially in extemporaneous prescription; but for officinal compositions they are less proper, as they soon grow too soft in keeping, and lose their form in a warm air.

As some difference is observed in the hardness of a plaster for the breast or stomach, and one that is to be applied to the limbs, the following proportions are generally directed. For a soft plaster, take one ounce of expressed oil, one ounce of wax, and half an ounce of any powder; for a harder, add an ounce more of wax, and half an ounce of powder.

M. Deyeux, in the 33d volume of the Annales de Chimie, has added some chemical refinements with respect to this officinal preparation, which merit our attention. He considers *plasters* to consist merely of the union of oil, or a mixture of oil and wax with metallic oxides. Those in which these substances are united with vegetable juices he styles *ointments*.

The union of oils with metallic oxides he supposes to

be a true chemical combination, which some pharmaceutical authors have styled *soaps*; he thinks without reason, as they are neither soluble in water nor alcohol. In proof of the chemical union, he adds, that some metallic oxides, particularly those of iron, refuse to unite with oils; for, though they apparently mix, yet, when diluted, the oxide separates, which is by no means the case with similar combinations. The oxides of lead, bismuth, and mercury, unite with oil, though not with equal facility.

There are three methods of uniting oil with metallic oxides: the first is by agitation, without heat. In this way the oxide of lead combines with oil; but the operation is slow and laborious: and, though the union appears to be complete, the plaster never attains a proper consistence. The second is to boil the oxide and oil with water, and in this case the water acts only as a *balneum mariæ*, to facilitate the union, by bringing the particles of the oil and oxide together in an attenuated state. By this process we usually obtain a plaster of a proper consistence. The third is the common method of uniting the oxide with the heated oil by agitation. Plasters, thus made, are always dark in their colour, and exhale a peculiar odour, which distinguishes them. In every process the oxide should be in the minutest state of division, particularly in the last, since the metal would be otherwise revived, which sometimes happens, particularly in a saturnine ointment, called by the French pharmacutists, *unguentum de la mere*; an event in part owing to the large proportion of animal oils which it contains. The only method of avoiding this inconvenience is to hasten the union, which is best effected by a minute division of the oxides. Though all oils unite with metallic oxides, the results are different. With oxides of lead, for instance, particularly litharge, linseed oil unites freely, and softens by the heat of the hand only: while, with olive oil, it is so dry as to admit of being powdered, and must be heated to be properly spread. In general, drying oils afford the softest plasters; and olive oil, digested with the root of *althæa*, gives a softer ointment than it would have done, previous to the process. Those oils which are not drying are preferable; but the olive oil, generally sold, is seldom uniform in its properties.

The metallic oxides differ perhaps as much as the oils. Litharge affords drier plasters than minium or the white oxides of lead. Other oxides may unite readily with oil; but a sufficient number of experiments has not yet been made. M. Deyeux suspects that the very pure red oxide of mercury, if finely powdered, so as to prevent its being deoxydated, might advantageously supersede the oxide of lead in many plasters.

When plasters, from age, become too dry, they must be moistened with a due proportion of oil; but, in general, the proportion of oil in those liable to become brittle by age is too small. The access of air often changes the colour of plasters, and very probably their qualities; so that they should be carefully guarded from it, especially those subject to such a change.

EMPLA'STRUM ADHESIVUM NIGRUM. The BLACK STICKING PLASTER, LADY'S COURT PLASTER, and the CHICHESTER PLASTER.

Dissolve twelve ounces of gum benjamin in twelve ounces of rectified spirit of wine: in a separate vessel

dissolve a pound of the best isinglass in five pints of pure water; strain each solution; mix them, and let them stand in a narrow vessel, that the grosser parts may subside: when the clear liquor is cold, it will form a jelly; and it must be warmed when spread. This quantity suffices for covering ten yards of half-yard-wide silk: the silk must be stretched in a frame, and the mixture spread on it with a brush. As each spreading dries, it must be repeated to the tenth or twelfth time; and a gloss is obtained by a light touch of the brush at the last operation.

Its use is generally known; but the following is an easy substitute: Dissolve a pound and a quarter of fine isinglass in five pints of water; and before it cools spread it on silk in the manner above directed.

*Emplastrum ad contusa Boerhaavii.* R. Bryoniæ in farinam reductæ ℥ ij. flor. sulph. ℥ i. hydrargyri cum sulphure ℥ iij. galbani puri, et s. a. soluti ℥ iv. emplastri de meliloto ℥ iv. ol. chamæmeli q. s. ut fiat emplastrum. The three last ingredients are to be melted together, and the powder stirred in. Modern practice adopts this, only using the emplastrum ceræ compositum, instead of that of melilot; and one ounce of olive oil in the place of the oleum chamæmeli: it is supposed to be a beneficial application, particularly in scrofulous indurations.

*Emplastrum anodynum.* Take four pounds of common plaster; melt it over a gentle fire, with an ounce and a half of common black pitch. When this is to be applied, mix with each ounce, weight, half a drachm of opium, and the same quantity of camphor in fine powder. It is said to be very efficacious in relieving old pains; but the proportion of camphor and opium may be doubled.

EMPLA'STRUM A'TTRAHENS. See EMPLASTRUM CERÆ, under CERÆ.

EMPLA'STRUM VESICATO'RIMUM. See CANTHARIDES.

EMPLA'STRUM CU'MINI. See CUMINUM.

EMPLA'STRUM COMMUNE; formerly called *diachylon*, now *lithargyri emplastrum*.

Take of olive oil, one gallon; of litharge finely powdered, five pounds; boil them together with about a quart of water over a gentle fire, continually stirring till the oil and the litharge are united, and acquire the due consistence of a plaster; and if the water is wasted before the operation is finished, more water (previously heated) must be poured on.

As soon as the mixture is warm, begin to stir it: in about four hours the boiling will be completed; but to ascertain this, drop a little on a tile to cool, by which you will easily discover whether the litharge be dissolved; the boiling must be continued very gently, or the plaster will be black; perhaps boil over suddenly. If water should be added that is not very hot, the plaster will explode with violence, and be wasted; an accident which will happen with hot water, if the plaster is too hot. If the composition proves discoloured, the addition of a little white lead and oil will improve it; but if expected to be very white, true olive oil must be used.

*Emplastrum nigrum Domini Sharp.* seu *Emplastrum cerussæ*.—R. Olei olivarum ℥ xij. ceræ flavæ ℥ ij. ss. cerussæ ℥ x. Let the oil and wax be melted together, the ceruss added, and the whole boiled to a consistence of a plaster. Sharp used it as an application to diseased knees; but Kirkland employs a plaster of red lead

and oil, boiled to a dark brown colour, for the same purpose.

*Emplastrum stimulaus*, seu *ammonia*, STIMULANT PLASTER, or PLASTER OF AMMONIA.—R. Saponis ℥ ij. emplastri lithargyri ℥ ss. ammoniæ muriatæ ℥ i. Let the soap and litharge plaster be melted together, and when nearly cold, the muriated ammonia, in fine powder, be stirred in. This plaster must be made at the time of application, else the alkali, set at liberty by the decomposition of the muriated ammonia, will fly off, and frustrate the intent of the remedy. In delicate and irritable skins, the quantity of the ammonia must be lessened, lest the plaster blister the part. In chronic enlargement of the joints, or tumours without inflammation; in some scrofulous affections of the knee or elbow joints; but particularly in those gelatinous swellings which frequently form on the olecranon, it has been of singular service, probably by stimulating the absorbents, and increasing their power of action.

EMPLA'STRUM SAPONIS. R. Saponis ℥ ij. emplastr. lithargyri ℥ iij. These, melted together, must be boiled to a proper consistence. It is a mild discutient, and to tumours of various kinds is considered as an useful application; but as soap is much more advantageously used in liquid forms, the practitioner will rarely be induced to apply it in that of a solid.

EMPLA'STRUM STOMA'CHICUM. STOMACH PLASTER. Now called *emplastrum labdani compositum*, COMPOUND PLASTER OF LABDANUM.

Take of soft labdanum, three ounces; of frankincense, one ounce; cinnamon and expressed oil of mace, of each half an ounce; of essential oil of mint, one drachm: add to the frankincense, first melted, the labdanum heated, till it becomes soft, and then the oil of mace; afterwards mix the cinnamon with the oil of mint, beat them together in a warm mortar, and keep the whole in a vessel well closed.

The plasters should be frequently renewed, and applied on the five lower ribs of the left side, towards the back. It has been supposed of use also to promote the suppuration of indolent tumours.

EMPLATTO'MENA, (from *εμπλασσω*, to obstruct). See EMPHRACTICA.

EMPNEUMATO'SIS, (from *εμπνεω*, to blow into, or inflate). An inflation of the stomach, the womb, or other parts.

EMPO'RIMUM, (from *εμπορος*, negotiator, from *εμπαρεω*, to negotiate). See CEREBRUM.

EMPRION, (from *πριω*, to saw). SAW-LIKE. A kind of pulse mentioned by Galen, in which the artery is unequally distended in different parts.

EMPROSTHO'TONOS, (from *εμπροσθεν*, forwards, and *τεινω*, to bend). A spasm which bends the body forward, and confines it in that position. Celsus, lib. iv. cap. 3, restricts the term to a convulsive stiffness of the neck, by which the chin is fixed on the breast. See TETANUS.

E'MPTYSIS, (from *πρω*, to spit out). SPITTING OF BLOOD; a discharge which comes only from the mouth, fauces, and parts adjacent. Aretæus.

EMPYEMA, (from *εν*, within, and *πυον*, pus, or matter). The ancients called all internal suppurations *empyema*, (see *εμπεμα*); but at present this name is confined to a collection of purulent matter, lying loose in the cavity of the breast, and lodging on the dia-

phragm. Dr. Cullen considers it as a consequence of pneumonia, and says, its symptoms are, a remission of pain, after a pleurisy has terminated in suppuration, often after a vomica; whilst a difficulty of breathing, cough, uneasiness in lying down, and hectic fever, continue: frequently attended with a sensation of some fluid fluctuating in the breast, and symptoms of a hydrothorax.

Arctæus, lib. i. De Causis et Signis Morborum Chronicorum, cap. 9, says, "They who have purulent abscesses in the cavities of the body, whether within the thorax or below the diaphragm, if the pus be discharged upwards, are called *εμπτυοι* (*emphyi*); if downwards, *apostomatici*. And if there be a suppuration in the thorax, and the pus be discharged through the lungs, it is called *εμπτυη*." But the moderns styled it only an *empyema* when purulent matter floats upon the diaphragm. If matter is lodged on both sides of the breast, there are two empyemas.

The pus, that forms an empyema, may be from an abscess in the lungs, pleura, mediastinum, pericardium, or diaphragm; or perhaps from that inflammatory exudation, or inspissated serum, which, Dr. Hunter observes, resembles pus, often found in large quantities in the cavities of the breast, belly, &c. Wounds in the breast may also evacuate their matter into its cavity, and prove a cause of this disease. Le Dran informs us, that he met with instances of abscesses in the liver making a way through the diaphragm, and emptying themselves into the breast. Some instances of this have occurred in modern times, and small apertures in the diaphragm, through which pus has passed, anatomists have observed and described. (Pemberton on the Diseases of the Abdominal Viscera, p. 36). From Sauvages may be collected six varieties, although they are not always capable of being distinguished, viz. *Empyema à peripneumonia*; and *vomica*; *empyema pleuræ*; *mediastina*; *diaphragmatis*; and *intercostale*.

When any fluid matter is collected in the cavity of the breast, it may be known by the following signs: the breathing is short and laborious; expiration is more difficult than inspiration; the patient perceives a fluctuation when he changes his position from side to side, or presses the abdomen against the edge of a table; sometimes there is an enlargement of the cavity of the thorax, and an œdematous fulness of the skin and flesh of one or both sides of the chest; a dry cough; a slow fever; heat at the extremities of the fingers; and hollowness of the eyes. The patient cannot lie on the sound side, though in hectic he can only sleep easily on it. The kind of matter can only be known by the nature of the disorder, which preceded an accumulation, and from the concomitant symptoms. The matter may be blood or pus: and the latter of these may be suspected, when there hath been an inflammatory disorder in the lungs, pleura, or other parts in the breast, attended with symptoms of suppuration, and particularly if viscid sweats attend.

If the matter of an empyema be not speedily expectorated, the patient dies of a consumption, with a hectic fever, which is always exasperated at night. If the mediastinum is corroded, upon opening the thorax a sudden suffocation must ensue. If the empyema is of long standing, the strength decayed, with a colliquative diarrhœa, and a wasting of the body, the operation, instead of relieving, hastens the death of the patient. When

this disorder is merely local, the operation may succeed, but if the habit be strumous, or otherwise unsound; if fever, coughing, thirst and other symptoms, are either numerous or considerable in their degree; there is but little hope of recovery. The operation is also ineffectual if the lungs adhere considerably to the pleura, or if the matter lodged on the diaphragm was emptied from a cyst.

The surgical method by which relief is obtained is called THE OPERATION FOR THE EMPYEMA. The fluid to be voided by this operation is matter. In this case, therefore, only the assistance of a surgeon is required; for blood will be gradually absorbed, and need not be removed by any artificial opening. Gooch relates a case in his Medical Observations of air in the thorax producing the symptoms of an empyema: it passed through an ulcer in the lungs; but the ulcer healing, the air was evacuated by the operation for the empyema, and a complete cure effected.

The manner of operating is to fix on the part for the perforation; then, with a knife or a trochar, a passage may be formed for the offending air. Whether an opening is made by means of a knife or a trochar, as Albinus hath observed that the diaphragm on the right side ascends higher into the thorax than on the left, it may be proper to pierce it on the right side between the third and fourth spurious ribs; but on the left, between the second and third, and at about half or two thirds of the distance from the sternum to the vertebra; for here the muscles are thinnest, the artery is concealed under the rib, and the diaphragm at a due distance. The puncture must be made with the utmost caution, lest there should be an adhesion of the lungs to the pleura; a canula for a time left in the wound, and the wound itself kept open. Matter, lodged in both cavities of the thorax, requires that the operation be performed on each side. See Hippocrates, Galen, Arctæus, Boerhaave, with Van Swieten's Comments, Le Dran's Operations, Sharp's Operations, Heister's Surgery, Bell's Surgery, vol. ii. p. 383, Kirkland's Medical Surgery, vol. ii. p. 175, Pearson's Principles of Surgery, vol. i. p. 94, White's Surgery, p. 303.

EMPYEMATA, (from *εμπτυημα*). So the ancients called suppurating medicines; for they named an internal collection of pus *empyema*.

EMPYI. Purulent or suppurated, or those who have purulent abscesses internally.

EMPYREUMA, (from *εμπυρεω*, to kindle, or *ενπυρι*, in the fire). In chemistry it is the offensive smell and taste which distilled waters, or other substances, receive from being too much exposed to the fire, when their mucilage is burnt.

EMPYREUMATICA, O'LEA, (from *εμπυρευμα*). EMPYREUMATIC OILS. Oils both of the animal and vegetable kind, distilled with a heat greater than that of boiling water; and thus receiving a burnt smell. These oils are sometimes considered as of a distinct class; but they are only burnt, and dissolve more or less in rectified spirit of wine; are acrid; by repeated distillations volatile, and almost free from their disagreeable smell. In some respects they resemble the essential oils of vegetables. They are considered as powerful antispasmodics: that chiefly used is the *oleum Diphelii animale*.

EMPYROS, (from *εν*, and *πυρ*, fire). One labouring under a fever.

EMULGENS, (from *emulgo*, to milk out). EMUL-

GENT, milking out. The term is applied to the arteries and veins, from the aorta and vena cava to the kidneys. According to the ancients, they strained and milked the serum through the kidneys.

EMULGENTES ARTERIÆ and VE'NÆ. See RENALES ARTERIÆ and VENÆ.

EMULSIO, (from *emulgeo*). Medicines of any kind resembling milk; though the London college has rejected that term, and supplied it with *lac*. They are generally made from farinaceous seeds, beat up with some fluid, with which their oily parts are intimately blended; and chiefly used for common drink in acute disorders. For the *emulsio communis*, or *lac, amygdalæ, emulsio absorbens*, and *emulsio, camphorata*, see AMYG. DALE DULCES.

EMUNCTO'RIA. EMUNCTORIES, (from *emungo*, to clean, *wipe away*, or *draw off*,) the passages, particularly the glands, by which excrementitious matters are evacuated. The parotides supposed to receive the excrements from the brain, the axillary glands from the heart, and the inguinal from the liver, were *κατ' ἐξοχην*, thus named. It is, however, often the appellation of glands which separate useful fluids.

ENÆ'MOS, (from *εν*, and *αἷμα*, blood,) topical medicines appropriated to bleeding wounds. Hippocrates.

ENÆORE'MA, (from *αιωρ*, *sublime*,) the pendulous substance which floats in the middle of the urine, *sublimamentum, nubecula suspensa, sublimatio urinæ*.

ENAM'EL. See DENS.

ENAR'GES, (from *αργος*, white, or evident). Hippocrates applies this epithet to dreams.

ENARICY'MON, (from *εν*, *αρι*, soon, and *κνω*, to conceive). See ARICIMON.

ENARTHRO'SIS, (from *εν*, in, and *αρθρον*, a joint). See DIARTHROSIS.

ENCA'NTHIS, (from *εν*, in, and *κανθ*, an angle of the eye,) an encysted tumour on its inner angle. At the first a tubercle appears on the caruncula lachrymalis, or on the cuticle adjacent; afterwards this tumour extends over the pupil of the eye. The tears in consequence trickle down the cheeks, the sight is impaired, the countenance deformed, and the eyes inflamed. When of a milder nature, it may be destroyed by gentle escharotics; the belly should be kept lax, and an issue in the arm, or a perpetual blister between the shoulders, should continue to discharge.

When this tumour is malignant, it is attended with pain, is of a livid hue, and often cancerous. If manifestly cancerous, palliatives only are to be used; but otherwise, the whole tumour and its cyst should be dissected, raising it with the forceps, to avoid cutting either the eye or the caruncle: if the latter is hurt, the tears will always run down the cheek; so that it is safer to leave a little of luxuriant flesh, and to destroy it afterwards with a caustic. See ECTROPIUM; Heister's Surgery; and White's Surgery, p. 231.

ENCA'RDION, (from *εν*, and *καρδια*, the heart). See MEDITULLIUM.

ENCA'RDIIUM PRE'MNU. The heart and marrow of the trunk of trees; the tender medullary substance which grows on the tops of the great palm tree. Dioscorides. By Theophrastus styled *encephalus*.

ENCATALE'PSIS, (from *εν*, and *καταλειπω*, to leave). See CATALEPSIS.

ENCATHI'SMA, (from *εγκαθηναι*, to sit in). See SEMICUPIUM.

ENCAU'MA, (from *εν*, and *καιω*, to burn). The scoriae of silver, as well as the mark left by a burn, and a pustule produced by the same cause. It is also the appellation of a superficial ulceration on the eye. Those ulcerations on the eyes, from defluxions of humours, receive, according to Ætius, different names: when formed on the pupil, covering a great part of it, and of a bluish colour, it is called *caligo*: when the ulcer is less wide, but deeper, and seated in the pupil, *nubecula*: when the surface of the pupil appears rough, and of an ash colour, *epicauma*: and when, after a fever, the ulcer has a sordid crust, seated either on the pupil or the white part of the eye, *encauma*; which when fixed in the pupil, all the humours of the eye are mixed, and the organ is destroyed. In the beginning of these cases, relief is sometimes obtained by keeping the bowels loose. White's Surgery, p. 229.

ENCAU'SIS, (from the same). A BURN; or rather the inflammation caused by it. It is also that action of external heat upon the body, as of the sun, or fire, and a synonym with *deustio*; sometimes an appellation of the HEART BURN, with thirst; in Dr. Cullen's Nosology synonymous with *erythema* and *ambustio*.

ENCE'PHALON and ENCE'PHALUS, (from *εν*, within, and *κεφαλη*, the head). The encephalon includes the cerebrum, the cerebellum, the medulla oblongata, with their membranes.

ENCEPHALOC'E'LE, (from *εγκεφαλος*, cerebrum, and *κελε*, a tumour). See HERNIA CEREBRI.

ENCE'RIS, (from *εν*, and *κηρος*, wax). Bits of wax found in plasters as they cool.

ENCHARA'XIS, (from *εν*, and *χαρσσω*, to scarify). See SCARIFICATIO.

ENCHEIRE'SIS, (from *εν*, and *χειρ*, the hand). This word imports the manual treatment of any subject, and is a part of the title of one of Galen's works on dissection.

ENCHO'NDROS, (from *εν*, and *χονδρος*, signifying both a grain and a cartilage,) granulated and cartilaginous.

ENCHO'RIOUS, (from *εν*, and *χωρος*, a region, or country). See ENDEMIUS.

ENCHRI'STA, (from *εγχριω*, to anoint). Liniments to anoint any part.

ENCHU'SA. See ANCHUSA.

ENCHYLO'MA, (from *εν*, and *χυλος*, juice). See ELIXIR.

ENCHY'MA, (from *εγχυνω*, to infuse). INFUSION, or a sanguine plethora.

ENCHY'MATA, (from *εγχυνω*, to pour into). Liquid medicines to be poured into the eyes or ears.

ENCHYMO'MA, (from the same). In the writings of the ancient physicians it implies that sudden effusion of blood into the cutaneous vessels which arises from joy, anger, or shame, and, in the last instance, is usually called BLUSHING. Dr. Hunter thinks it a nervous affection; but Dr. Whytt, with more propriety, ascribes it to the increased action of the smaller vessels, which has been attributed to a nervous connection, but which we suspect, though less obvious, is very general, over the whole surface.

ENCHYMO'SIS. (from the same). An extravasa-

tion of blood, which makes the part appear livid; sometimes synonymous with *ecchymosis*.

ENCHY'SA. See ANCHUSA.

ENCHY'TOS, (from *εγχυνω*, to *infuse*). An epithet for a fluid injected into any cavity of the body.

ENCLY'SMA, (from *εν*, and *κλυζω*, to *clean*). See ENEMA.

ENCÆ'LIA, (from *εν*, and *κοιλια*, the *belly*), the contents of the abdomen.

ENCOLPI'SMOS, (from *εγκολπιζω*, to *insinuate*). An uterine injection.

E'NCOPE, (from *εν*, and *κοπτω*, to *cut*). An incision; and, figuratively, an impediment.

ENCRA'NION, (from *εν*, and *κρανιον*, the *skull*). See CEREBELLUM.

E'NCRIS, (from *εγκρις*). A cake made of fine meal boiled in oil, and sweetened with honey.

E'NCYMON, (from *εγκυνω*, to *conceive*). Pregnant.

ENCY'STIS, (from *εν*, and *κυστις*, a *bag*). See NÆVUS.

ENDEDINE'MENOS, (from *ενδιναω*, to *turn round like a vortex*), an epithet for the eyes, which perpetually turn in their orbits.

ENDEI'XIS, (from *ενδεικνυμι*, to *show*). See INDICATIO.

ENDE'MIAS, or ENDE'MIUS, (from *εν*, and *δemos*, people,) *enchorios*, *popularis*. A term applicable to diseases common to the inhabitants living in one country, from a cause connected with it, as intermittents with the marshes of Essex, and fens of Cambridgeshire; the swelled throat in the Alps; and the plica and pertussis in Poland. It is opposed to EPIDEMIUS, q. v.

E'NDESIS, (from *εν*, and *δεω*, to *tie*). A LIGATURE, BAND, or CONNECTION.

E'NDICA. A sediment at the bottom of a fluid; called also *mose hazuana*. Rulandus.

E'NDIVA, (quasi *eundo viâ*, from its frequent occurrence,) *intybum sativum*, *seriola*, *cichoreum endivia* Lin. Sp. Pl. 1142. *Endivia vulgaris*, ENDIVE. This plant is in common use as a salad: it very much resembles succory, both in its appearance and virtues. It is etiolated, viz. blanched, by excluding the light. Without this process it is bitter, and not eatable. The Batavian endive, whose leaves are not deeply crenated, requires no previous etiolation. It is considered as warmer than lettuces, but differs little in its properties from other salads.

E'NDIVA ERECTA LUTEA NAPIFOLIA. See LAMPŒANA.

ENELLA'GMENOS, (from *εναλλαττω*, to *alternate*). An epithet applied to the joints of the vertebræ, because of their alternate or mutual receptions and insertions.

E'NEMA. A CLYSTER, (from *ενιημι*, to *inject*) *enclyisma*, *catlaysma*, and *lotio*. Any liquid medicine injected into the anus. Clysters are usually injected by means of a bladder and pipe, called *clusma*, *fistula*, *auliscos*; from whence *fistula armata*, *pipe*, and *bladder*: but in many other countries a syringe is always used, by which the liquor is thrown up further into the bowels.

The quantity of liquor used in each clyster will vary according to the age of the patient and intention proposed. For infants, two ounces are sufficient; a child

of six years old, from six to eight ounces; a youth of fourteen years, from eight ounces to a pint; and to an adult, from a pint to a pint and half. In general, the bulk should be considerable; for they stimulate from their bulk alone, and a quart of milk and water will often produce the appropriate effect; a circumstance of some utility, when the too anxious friends dread every evacuant. When the more active purgatives are thus combined with increased bulk, they seldom fail.

Clysters seldom reach beyond the sigmoid flexure, or that turn of the colon, on the left side, before its straight direction obtains for it the name of the rectum. They thus operate chiefly by stimulating the lower part of the gut, and evacuate only to the extent which that stimulus reaches. They are of little use, therefore, as evacuants, unless a purgative has been taken, whose effects we wish to hasten. This is often of considerable service where only small doses of cathartics can be retained; for by these means they prove effectual; and frequent solicitations by clysters produce, in such circumstances, the best effects.

In diarrhœas, and all disorders where the intestines are weak, or whenever the clyster is to be retained, the quantity for an adult should not exceed five or six ounces.

In ardent fevers, and inflammations of the bowels, they answer the end of a fomentation, and should be administered from a pint to a quart. In putrid fevers, this mode of introducing the bark and fixed air into the constitution has been adopted, it has been said, with success. Nourishment may be conveyed by clysters, when, from some complaint of the mouth, throat, or stomach, nothing can be swallowed or retained: many have been thus supported during several weeks. In such cases a quarter of a pint of rich broth is injected, with thirty or forty drops of tinctura opii, every five or six hours, and bark with port wine has been injected in the same way. The effects are not, however, so decidedly beneficial as they have been represented.

Clysters should never be either hot or cold when used; but so warm, that, when inclosed in a bladder, the heat gives only an agreeable sensation to the closed eye lid.

When a clyster is intended only to evacuate, three or four ounces of common salt, or as much soap in a pint and half of water, are sometimes equally effectual with any quantity of the other purging medicines.

When a very powerful stimulus is required in purging clysters, it is usual to mix emetics with them, and of these the vinum antimonii merits, it is said, the preference. But any of the more active purgatives will equally succeed; and there is not a more effectual purgative clyster than three drachms of the pulp of colocynth, boiled for a quarter of an hour in a sufficient quantity of water, to strain off a little more than a pint. To this should be added two ounces of oil, and as much vitriolated magnesia.

The usual method of injecting clysters is very inadequate, and often ineffectual. An injecting syringe, which holds a pint and half, is the proper instrument; and it is sometimes of advantage to have a lateral pipe, by which it may be supplied without withdrawing. We might thus even fill the colon, and produce many beneficial effects; since a fomentation could be in this way effectually applied to many important parts, when in a

state of inflammation, or otherwise diseased. De Haen, by such an instrument, filled the colon of a dog, and in some experiments even conquered the obstruction which its valve offers.

E'NEMA EX A'MYLO. See AMYUM.

E'NEOS. *Vain, empty, or useless.* The Greeks call those who are unable to perform the common offices of life, as dumb, deaf, or foolish persons, *ενεοι*.

ENE'RGIA, (from *εν*, and *εργον*, a work). ENERGY; force, vigour, efficacy.

ENERVA'TIO, (from *enervo*, to weaken,) an equivocal term, signifying aponeurosis or debility.

EN'FLURE DES JAMBES. See LYMPHÆ DUCTUS.

EN'FONDE. See CASSADA.

ENGISO'MA, (from *ενιζω*, to draw near). An instrument formerly used about fractures of the cranium; and from hence employed to signify a fracture of the cranium, in the middle of which the bone presses upon the membranes of the brain, resembling a *γείσων*, or *pent house*.

ENGOMPHO'SIS, (from *εν*, and *γομφος*, a nail). See GOMPHOMA.

ENGO'NIOS, (from *εν*, and *γωνία*, an angle), the bending of the arm at a right angle. Hippocrates.

ENGO'RGEMENT LAITEUX. See LYMPHÆ DUCTUS.

ENHÆ'MON, (from *εν*, and *αίμα*, blood). STYPTIC. The name of an astringent plaster in Myrepsus.

ENI'XA, (from *enitor*, to endeavour). A WOMAN IN CHILD BED.

ENI'XUM, (from *enitor*, to produce); the appellation of a neutral salt. See NEUTRI.

ENI'XUM PARACE'LSI SAL. From the discoverer Paracelsus: *kali vitriolatum*.

ENNEA'NDRIA, (from *εννεα*, *novem*, and *ανδρ*, *maritus*): the ninth class of the Linnæan system, comprehending such hermaphrodite flowers as have nine stamina.

ENNEAPET'ALUS, (from *εννεα*, *novem*, and *πτελον*, a flower-leaf). Having nine petals.

ENNEAPHARMACOS, (from *εννεα*, nine, and *φαρμακον*, a medicine), a composition of nine simple ingredients. It is also the name of a pessary mentioned by Galen and Ægineta; of the *antidotus Heraclidis*; and of several plasters mentioned by Ætius and Celsus.

ENNEAPHY'LLUM, (from *εννεα*, nine, and *φυλλον*, a leaf). See HELLEBORUS NIGER HORTENSIS, &c.

ENOCHDIA'NA VI'TA. A VERY LONG LIFE; the life of Enoch. Paracelsus.

ENRY'THMOS, (from *εν*, and *ρυθμος*, number). See ARYTHMUS.

ENS. AN ENTITY, or thing really existing. In Paracelsus *ens* imports the power, virtue, and efficacy, which a thing exerts upon our bodies.

ENS PA'RVUM SAPIE'NTUM. It is soap made by mixing fixed alkaline salt with distilled vegetable oil. The salt must be quite hot when mixed with the oil, for the least portion of water prevents their union: after their combination they are to be placed some time in a subterraneous place. A small quantity of the salt remaining on the surface of the oil will attract water, and prevent the success of the process.

ENS PRI'MUM SALIUM. See CIRCULATUM.

ENS PRI'MUM SOLA'RE. See ANTIMONIUM.

ENS VE'NERIS. See FLORES MARTIALES, under FERUM.

ENSA'TUS, (from *ensis*, a sword). In botany it means shaped like a sword.

ENSIFO'RMIS CARTILAGO, (from *ensis*, a sword, and *forma*, a form). The SWORD LIKE CARTILAGE, called also *xiphoides*; *mucronatum os*, or *mucronata cartilago*; by Hippocrates, *chondros*; and when bifurcated, *furcula* or *furcella inferior*. It is the cartilage at the bottom of the sternum; but the ancients often give the name of *ensiformis* to the whole breast bone. Dr. Hunter observes, that "if this cartilage be forced inwardly by a blow, it will occasion vomiting and violent pains, by pressing against the pylorus: in this case it would be proper to lay it bare and elevate it; but the diaphragm arising partly from it would probably replace it." From the form, or from accidents in this cartilage, many diseases arise; as a cough, pain in stooping, and difficult breathing. These symptoms are accounted for, when we consider that the diaphragm is attached to it, and that the great lobe of the liver and the stomach lie immediately under it.

ENSTA'CTON, (from *εν*, and *σταζω*, to distil). INSTILLATION. The name of a liquid collyrium in Galen, which Ægineta calls *stacticon*.

ENTA'LI. FOSSIL ALUM. See VAS.

ENTA'TICA MEDICAME'NTA, (from *εντεινω*, to strain). Medicines that provoke venery. Cælius Aurelianus calls them *satyrica*.

ENTA'TICON. The name of a plaster in P. Ægineta.

E'NTERA, (from *εντος*, *within*), the bags in which were inclosed medicines for fomentation. Hippocrates.

ENTERADE'NES, (from *εντερον*, an intestine, and *αδην*, a gland). The INTESTINAL GLANDS. See INTES-TINA.

ENTERE'NCHYTÆ, (from *εντερα*, the intestines, and *εσχυω*, to infuse). Instruments for administering clysters.

ENTERI'TIS, (from *εντερα*, intestines). See INFLAMMATIO INTESTINORUM.

ENTERI'TIS MESENTE'RICA, (from the same, and *μεσεντερια*, *mesentery*). See INFLAMMATIO MESENTERII.

ENTEROCE'LE, (from *εντερον*, an intestine, and *κηλη*, a rupture). See HERNIA SCROTALIS.

ENTEROCE'LE OVULA'RIS. A rupture of the intestines through the foramen ovale.

ENTERO EPIPLOCE'LE, (from *εντερον*, *epiploon*, the omentum, and *κηλη*, tumor,) when both the omentum and intestines protrude through the integuments of the belly.

ENTERO-HYDROCE'LE, (from *εντερον*, *υδαρ*, water, and *κηλη*, a hernia). A dropsy of the scrotum, with a descent of the intestine.

ENTERO'MPHALOS, (from *εντερον*, and *ομφαλος*, the navel). A rupture of the intestine at the navel. This seldom happens to women in labour, or from labour; but it often occurs in those debilitated by numerous births; to women who are fat and indolent.

E'NTERON, (from *εντος*, *within*). INTERNAL and INTESTINE. In Hippocrates Epid. 6. § 4. ap. 3. *enteron* signifies simply the colon.

ENTEROPHYTUM, (from *εντερον*, and *φυτον*, a plant). The sea chitterling, which grows in the shape of a plant.

ENTERORAPHIE, (from *εντερον*, and *ραφη*, a suture). A suture of the intestines. It is performed with the glover's stitch, and the end of the thread must be left beyond the external wound, to connect both, in order to form an adhesion, or an artificial anus.

ENTEROSCHOE'LE, (from *εντερον*, *οσχον*, the scrotum, and *κηλη*, a hernia). See HERNIA SCROTALIS.

ENTHEMA'TA, (from *εντιθημι*, to put in). Medicines applied immediately to recent wounds, in order to prevent an inflammation, or stop a hæmorrhage.

ENTHE'TOS, (from *εντιθημι*, to put in). Any thing introduced, but particularly lint introduced into the nose to stop a hæmorrhage.

ENTHLA'SIS, (from *ενθλαζω*, to press upon,) illness; a contusion, with the impression of the instrument by which it happened.

ENTHUSIA'SMUS, (from *ενθουσιαζω*, to rave). An heated imagination, when a person deeply contemplating religious subjects loses his reason, and sees strange sights, or hears the noise of musical instruments.

ENTRICHOMA, (from *εν*, and *τριχωμα*, the hair). The edge of the eye lid on which the hairs grow.

ENTRIMMA, (from *εν*, and *τριβω*, to grate, or triturate). See INTRITUM.

ENTROCHUS, (from *εν*, and *τροχος*, a wheel). An oblong stone nearly as thick as the finger, from one to two inches long; bluish, composed of joints frequently found in clay pits. Sometimes the joints are found separate, and are called *trochiteæ*. It is a part of the arm of a petrified star fish, or a similar sea animal. It is always hardened with sparry matter, and, like it, is supposed to be diuretic. A trochite, when found separate, is nearly an inch in diameter, with a hole in the centre; varying in thickness; when broken, it is glossy and shining.

ENTROP'NIUM, (from *εν*, and *τροπω*, to turn in). Introversion of the eye lid. See TRICHIA.

ENTYPO'SIS, (from *εντυπω*, to make an impression). The acetabulum of the humerus. It is not used by any medical writer, but mentioned by Julius Pollux.

ENUCLEA'TIO, (from *enucleo*). The taking a kernel from a nut; figuratively, clearing a difficulty.

E'NULA, (a corruption of *Helenium*; so called from Helene, the island where they grow,) *aroma germanicum*, *enula campana*, *aster*, *omnium maximus*; SCABWORT, and ELECAMpane. *Inula Helenium* Lin. Sp. Pl. 1236.

It is a large plant, with long, wrinkled leaves, that are serrated; of a pale green colour above, and hoary underneath: the flowers are yellow, of a discous kind, and followed by oblong seeds, winged with down; the roots are short and thick, unctuous to the touch; brown or blackish on the outside, and whitish within. It is perennial, grows wild in moist rich soils, and flowers in June.

The fresh roots have a weak but not very grateful smell; when perfectly dried, they are more pleasing; when chewed, they discover at the first a kind of rancid glutinous taste, quickly succeeded by an aromatic bitterness, which by degrees becomes more pungent. They

are diaphoretic, diuretic, and stomachic; if taken freely, they are gently laxative; powerfully attenuate viscid humours, and assist expectoration in coughs and humoral asthmas. The ancients had a high opinion of their virtues, and from their sensible and chemical qualities they promise to be a medicine of some efficacy. Elecampane is now chiefly recommended where the digestion is impaired; in pulmonic affections, and uterine obstructions; sometimes as an anthelmintic, and in mucous discharges from the rectum: but Dr. Cullen, notwithstanding its allowed qualities, says, still he is at a loss to determine what are its peculiar virtues. We have not extensively used this remedy, but have chiefly found it as a warm expectorant, and have employed it with most success in those cases of hectic where the bronchial glands were considerably weakened, and the discharge was copious and watery.

The spirituous extract is the most active preparation; but the watery is more abundant, and scarcely inferior to the former. Neumann obtained from one ounce of the dry root, by means of water, six drachms and a half of extract; but with spirit, only two drachms and a half. Much of the aromatic warmth and bitterness of these roots reside in the less volatile parts, which are, therefore, preserved in the watery extract. In distillation with water an essential oil arises which concretes into white flakes, and partly into an unctuous mass, like soft wax. Thirty ounces of roots afford about a drachm of this oil. The younger Geoffroy observes, that this oil resides in the exterior part of the root, near the bark. When this concrete oil is newly distilled, it strongly possesses the flavour of elecampane; but soon loses its smell by keeping.

*Extractum Enulæ Campestris*.—Boil elecampane roots in water; press and strain the decoction. When settled, pour off the clear liquor, and boil it to a consistence of pills, taking care to prevent its burning towards the end of the operation. The dose may be from ʒ i. to ʒ i. in a lax state of the fibres of the stomach, and in some disorders of the breast.

The dose of the root may be two scruples: in infusion, one drachm; and from ʒ ij. to ʒ ss. in decoction.

The candied elecampane root is prepared in the same manner as the eringo root. (See ERYNGIUM.) Raii Hist.; Lewis's *Materia Medica*; Neumann's *Chemical Works*; Cullen's *Materia Medica*.

E'NULON, (from *εν*, and *ελον*, the gums). See GINGIVÆ.

ENURE'SIS, (from *εν*, and *ουρω*, to discharge urine). See URINE, incontinence of.

ENYPOSA'PROS, (from *εν*, *υπο*, and *σαπρος*, putrid). An epithet applied to the sputum of hectic patients, who generally compare it with the taste of a spoiled egg: a tendency to putrescency.

ENY'STRON, (from *ενωω*, to perfect). See ABOMASUM.

E'ON. The whole compass of the eye.

EPACMA'STICI, (from *επακμαζω*, to increase). See ACMASTICOS.

EPAGO'GION, (from *επαγω*, to draw out). An appellation in Dioscorides of the prepuce. See PRÆPUTIUM.

EPANADIDO'NTES PURE'TI, (from *επαναδιδωμι*, to increase). Fevers, whose heat is not pungent to the

touch in the beginning but becomes more so as they advance.

EPANADIPLO'SIS, (from *επαναδιπλω*, to reduplicate,) the reduplication of a fit of a semiteridian fever; that is, the renewal of the cold before the hot fit is completed.

EPANA'STASIS, from *επι*, and *ανιστημι*, to excite).

A TUMOUR OR TUBERCLE.

EPANCYLO'TUS, (from *επι*, and *αγκυλος*, crooked).

A bandage described by Oribasius.

EPANTHE'SMA, or EPANTHI'SMA, from *επι*, and *ανθος*, a flower. An EFFLORESCENCE. See EXANTHEMA.

EPAOI'DAI. See AMULETA.

EPAPHÆRESIS, (from *επι*, importing a repetition, and *αφαιρησις*, a removal). In Galen it is used to express a repeated evacuation by bleeding.

EPA'RGEMOS, (from *επι*, and *αργεμον*, the disease called *albugo*). An epithet for a person affected with the disorder of the eyes called *argemon*.

EPA'RMA, and EPA'RSIS, (from *επι*, and *αιρω*, to elevate). Any kind of tumour, but usually applied to the parotis.

E'PAROTH. See BOTRYS MEXICANA.

EPENCRA'NIS, from *επι*, *εν*, and *κρανιον*, the skull). A name of the cerebellum.

EPERLA'NUS; *viola marina*. The SMELT. This fish receives its first name from its pearl colour, and the second from its violet smell. It is very nourishing, and as easy to digest.

EPHEBÆ'ON, (from *επι*, and *ηδη*, the groin). See PUBIS OSSA.

EPHEDRA'NA, (from *εφεζομαι*, to sit upon). See CLUNES.

EPHE'LCIS, (from *επι*, *υφον*, and *ελκος*, an ulcer). The crust of an ulcer, a small abrasion, or bloody fragment coughed up.

EPHE'LIDES, (from *επι*, and *ηλιος*, the sun. SUN-BURNING, *æstates*, *nitiligo lentiginæ*, *lenticulæ*, from their size and colour resembling a lentil seed.) FRECKLES, TAN, MORPHEW, which seem only to differ in degree; they are yellowish coloured spots spread over the face, neck, and hands, brought on in particular constitutions by heat; they chiefly affect people of delicate complexions, and who have red hair, and are confined to those parts exposed to the sun; in winter they often disappear. Juice of lemons, mixed with sugar and borax finely powdered and digested for eight days, frequently remove them. Homberg also recommends bullock's gall, mixed with alum, and after the alum has precipitated, exposed three or four months to the sun in a close phial. Of the NITILIGO, or *morpheus*, Sauvages enumerates four, and of the EPHELIS, six species. Nosologia Methodica, vol. i. p. 127, 128.

EPHEM. GERM. An abbreviation of *Ephemérides Medicophysicæ Germanicæ*. Nov. is added when the new collection is referred to.

EPHE'MERA, (from *επι*, and *ημερα*, a day). A fever of one day's continuance only; *diaria febris*. The heat of the body is moderate, such as attends an excess of wine, or a violent passion. The pulse is somewhat full and quick, but soft and regular; the urine unchanged: neither is the complaint preceded by any sickness, yawning, propensity to sleep, or horror. It comes on suddenly, unattended with any pain of the head and

stomach, nausea, burning heat, or inquietude. The disorder sometimes goes off without any apparent evacuation; but oftener by a free perspiration, or at most a pleasant moderate sweat. It generally arises from watching, solicitude, sorrow, anger, inebriety, fatigue, heat of the sun, or inanition, and usually terminates in one, at the furthest, in two or three days. Nature commonly effects a cure. The fever described by Lommius, and other ancient authors, under this title, is evidently an exacerbation of the common febrile accession, in consequence of some of the causes mentioned. There is, however, an ephéméra of a different kind, marked by violent rigor, and succeeded by burning heat, which disappears at the end of the twenty-four hours, leaving only debility. It is the occasional recurrence of such ephéméræ which has induced nosologists to establish a genus which they style *erratica*, but which seems to have no existence. We have seen such ephéméræ frequently, without being able to trace their source. We have generally, however, had reason to suspect that they were owing to obstructed viscera, or at least connected with some internal disorder. They require no remedy but rest and warm diluting liquors. See Lommii *Observationes Medicæ*. Sauvagesii *Nosologia*.

EPHE'MERA DICHOMENE; the *febris erratica* of nosologists just mentioned.

EPHEME'RIDES, (from *εφημερις*, an almanack, as they may be foretold by the almanack). Van Helmont calls those diseases which seize the patient at particular times of the moon, *ephémérides ægrotórum*, the ALMANACKS OF THE SICK.

EPHE'MERON, (from *επι*, and *ημερα*, a day; because the flowers continue but a day). See HERMODACTYLUS.

EPHE'SIUM. The name of a plaster described in Celsus.

EPHIA'LTES, or EPIA'LTES, (from *εφαλλομαι*, to leap upon). See INCUBO.

EPHIA'LTIA, (from *ephialtes*; because it occasions the night mare). See PÆONIA.

EPHIDRO'SIS, (from *εφιδρω*, to break out into a sweat,) *hydropedesis*, *desudatio* and *mador*. Dr. Cullen places this disease in the class *locales*, and order *apocynoses*; and defines it a preternatural evacuation of sweat, one species only of which he considers as idiopathic; *ephidrosis spontanea*. The rest are symptomatic, of which he enumerates nineteen varieties—seven according to the diseases which they accompany, viz. *febrile*, *febricose*, *hectic*, *exanthematic*, *syncopie*, *scorbutic*, *saburral*; eleven, from the nature of the sweat; *lacteal*, *melleous*, *vinous*, *green*, *black*, *pale yellow*, *urinous*, *bloody*, *bluish*, *acid*, *arenous*; and one, from the part whence the sweat is effused, viz. *lateral*; or, more properly, *local*. The idiopathic ephidrosis is most frequently the result of debility. Sauvages has three or four times observed men who were afflicted violently with night sweats, that continued for months without fever, bringing on emaciation, debility, and loss of appetite: these were cured by cathartics, the mineral waters styled *acidulæ*, and milk; but amongst boys the disease used to continue long. These sweats seem to resemble DIABETES and CÆLIACA PASSIO, q. v. The sweating sickness, said to be peculiar to England and to Englishmen, in every climate, was a fever. See Cullen's Synopsis, and Sauvages's Nosolog. Methodica.

EPHI'PPIUM, A SADDLE. See SELLA TURCICA. It is called *ephippium*, from its resemblance to a saddle.

EPHO'DES, (from *επι* and *ὁδός*, a way). In Hippocrates it means the ducts or passages by which the excrementitious fluids of the body are evacuated; the periodical attack of a fever, from the common use of the term to express the attack of thieves; or the access of similar or dissimilar things which may be useful or hurtful to the body.

EPI'ALOS. An epithet of a fever, (from *ηπιος*, gentle, and *ἄλς*, the sea). Galen defines it to be a fever in which the patient labours under a preternatural heat, and a coldness at the same time; called by the Latins *guercera*. Hesychius confines it to the cold shivering preceding a fever; and other authors enumerate it among the varieties of tertian fever.

EPI'BOLE, (from *επι* and *βαλλω*, to be cast upon). See INCUBO.

EPICA'NTHIDES, (from *επι*, and *κῆνθος*, the angle of the eye). See CANTHI.

EPICA'RPIUM, (from *επι*, and *καρπος*, the wrist). See CATAPLASMA.

EPICAU'MA, (from *επι*, and *καιω*, to burn). See ENCAUMA.

EPICERA'STICA, (from *επι*, and *κεραυνυμι*, to mix, or *attemperate*). Medicines supposed to dilute obtund acrimony, and relieve troublesome sensations.

EPI'CHOLOS, (from *επι*, and *χολη*, bile). BILIOUS.

EPICHORDIS, (from *επι*, and *χορδή*, a gut). See MESENTERIUM.

EPICHO'RIOS, (from *επι*, and *χωρα*, a region). See EPIDEMIUS.

EPICŒ'LIS, (from *επι* and *κοίλις*, the eye lid). The UPPER EYE LID.

EPICO'LICÆ REGIO'NES, (from *επι*, super, and *κῶλον*, colon). The lateral or lumbar region; the parts of the body adjacent to the colon.

EPICRA'NIUM, (from *επι*, and *κράνιον*, the skull). See OCCIPITO FRONTALIS.

EPICRA'SIS, (from *επι*, and *κεραυνυμι*, to temper). A critical evacuation, or an attemperation of bad humours. When a cure is performed in the latter way, it is called *per epicrasin*. The term is often employed by the Galenists and Boerhaavians; but as we have no evidence of a depraved state of the fluids in the circulating system, we are neither anxious to "attemper" or "evacuate" them.

EPICTE'NION, (from *επι*, above, and *κτείνω*, fumes). The part above the pubes; and the fine lint which is wafted in the air where flax is dressing.

EPICYE'MA, and EPICYE'SIS, (from *επι*, and *κυω*, to conceive). EPIGONON. SUPERFETATION, SUPERIM-PREGNATION; a second conception whilst the woman is in a state of pregnancy: but this event never takes place. In Hippocrates it is a FŒTUS; sometimes a MOLE. See SUPERFETATIO.

EPIDE'MICA A'QUA. See ALEXITERIA AQUA SPIRITUOSA.

EPIDE'MIUS, (from *επι*, upon, and *δημος*, the people). *Epichorios; pandemius; popularis; regionalis morbus*. An epithet of diseases which at certain times are popular, and frequently attack; then for a time disappear, and again return.

The extensive influence of epidemic diseases has ex-

cited the greatest attention to their causes. In almost every ruder age they have been referred to the anger of their peculiar divinities, and sacrifices were instituted to reconcile them. More lately Dr. Webster has attempted to connect them with the eruptions of volcanos, or the devastation of earthquakes. A more sound philosophy, and more attentive observation have shown, that they are owing very often to the effluvia of neighbouring marshes, and their occasional appearance is connected with the prevailing wind which passes from the marsh to the habitations. Another cause of their prevalence is, the wind from the marsh coinciding with the time when the moist ground begins to appear, from the waters subsiding. This is the period of sickness; for the marsh, while covered with water, is innocuous. Another cause of epidemics is the weather. A long continued warm season, suddenly interrupted by a cold piercing wind, will produce a violent and extensive epidemic, which particularly attacks in the highest, and apparently the most healthy, situations; for this reason, that the inhabitants are there most exposed to cold. But if this interchange of weather occurs to the inhabitants of a crowded city, the epidemic will be highly putrid, and often fatal. Should contagion of a malignant kind concur, the devastation of the epidemic will increase in proportion. These are the concurring causes of the American yellow fever, and the late fatal epidemics in Spain.

There are, however, causes which we cannot investigate. Extensive epidemics appear, and travel in succession, with different severity, through every part of the globe that we are acquainted with. The destroying angel seems to move with a studied regularity, without our being able to arrest his steps or alter his course. We often find these inexplicable epidemics without much danger, influencing the appearance of diseases and their treatment. Thus, while some epidemics prevail, evacuations from the bowels are necessary in almost every complaint; even where, in appearance, unnecessary or contraindicated. In others, they are, with difficulty, borne in any disorder. This necessary attention to the prevalence of the constitution merits very particular attention; and the more extensive a physician's experience is, by so much will he be better able to treat the commonest disease.

Epidemics connected with the seasons or prevailing temperature may be easily traced, and we shall find them occasionally mitigated or severe: sometimes apparently stopped; at others exerting their power with increased virulence. The peculiar treatment, however, suggested by a general epidemic, should not at once be discontinued. The human constitution does not soon change; the alteration is gradual, and almost imperceptible: nor should the medical plans be altered till they are decidedly injurious.

When an epidemic has continued for some time, the body is habituated to the influence of the morbid cause; suffers less from it; and the health is more readily restored. At this time, remedies before useless are found to produce some salutary effects; and, at the end of an epidemic, we usually are told of a plan which never fails. On its return, these boasted plans are as ineffectual as before. In fact, they only combated, with success, a disease of reduced power.

We greatly want a judicious and well connected

account of epidemics. Dr. Webster has lately brought together a very extensive collection of facts of this kind, with the views formerly mentioned; but the chaff is so intimately mixed with the grain, that the salutary information is with difficulty selected. See also Observations on Epidemic Disorders, &c.

We cannot give a better view of the epidemics of the two last centuries than in the comprehensive abstract of Dr. Sims.

"1. The first epidemic constitution was as follows: The years 1590, 1591, 1592, were all exceedingly dry; as was part of 1593; afterwards very rainy weather until the end of 1597. In 1593 the plague killed eleven thousand five hundred and three in London; the same year it was prevalent in Alcmäär. A catarrh prevailed in 1597. The rainy weather began in Florence in 1592, during which a pestilential fever raged there, attended with a whitish tongue, and an inflammation, with ulcers about the throat and mouth.

"2. There was, in 1598, an excessive heat and drought, which continued next year; 1600, a severe winter; 1601, a drought of five months' continuance; 1602, a cold spring and summer, cold dry harvest and winter; the rest of this constitution very rainy, until the end of 1608, except seven weeks' frost in 1607. In 1603 the plague was imported from Ostend, where, and in the Low countries, it raged much, and killed thirty-six thousand two hundred and sixty-nine in London.

"3. In 1609, three months most rigorous frost, wherein the Thames became like a solid highway; 1610, an excessive hot dry summer, as were those of 1611 and 1612; 1616, 1617, and 1619. The winters of 1614 and 1615 great frost and snow; the rest of this constitution wet until the end of 1624. In 1609 the plague broke out in Alcmäär, as also in Denmark. In 1610 the Hungarian fever commenced in many places, and made great havoc for several years, so as often to be denominated a plague. About the same time the malignant sore throat is supposed to have commenced in Spain, where it killed incredible numbers. In 1611 the plague is said to have destroyed two hundred thousand at Constantinople. In 1614 the most fatal small pox spread all over Europe. In 1618 the sore throat broke out at Naples, where it continued its ravages for twenty years; it was preceded by a similar disorder among cattle. In 1618 the plague existed in Bergen. In 1619 it broke out in Denmark and in Grand Cairo.

"4. In 1625, a hard frosty winter, summer wet and hot; 1626 and 1627 excessively hot summers; 1630 and 1631, a great drought; the other years wet until 1634. In 1625 the plague killed thirty-five thousand four hundred and seventeen in London; it raged in Denmark both in 1625 and 1629; as also in 1625 in Leyden. In 1632 inflammations of the jaws prevailed, with an erysipelas in one or more parts of the body.

"5. In 1634, an excessively frosty winter; 1635, 1636, 1637, and 1638, very hot and dry summers; then very rainy years until 1643. In 1635 the plague in Leyden, and the camp fever spread all over Germany. In 1636 the plague was in London, whereof died thirteen thousand four hundred and eighty; in 1637, the plague in Denmark.

"6. The years 1643 and 1645 were remarkable for hot summers, followed by inconstant rainy seasons until

1650. In 1648 a fatal malignant fever was spread by the armies all over England; 1644, a malignant epidemic fever in Denmark; a similar fever in England, in which there was a roughness and sliminess of the throat and jaws, with pain, but scarcely any swelling or inflammation: it seemed only a mere defluction, by which the sick seemed choked, and for which astrigent gargles were useful. In 1650 a general catarrh prevailed.

"7. The years 1651 and 1659 had both very hot summers, and proved mostly dry; thence to 1655 very wet. The winters of 1651 and 1658 remarkably cold. In 1651, in the country about Rome, a contagious epidemic quinsy prevailed, and made terrible slaughter among children. A small ulcer arose in the mouth, for which juice of wood sorrel, syrup of pomegranates, with the bark, and chiefly the acid of vitriol, were useful. All that took these medicines recovered; but those who were not tractable, and refused medicines, died: it did not seize adults, nor the aged. In 1654 the plague was in Denmark; and in 1655, and the two following years, it prevailed exceedingly in the south of Europe; the agues likewise of these hot years were malignant, and spotted fevers were very common. In 1664, after a mild rainy winter, a malignant purple fever raged in Prussia, and killed great numbers under twelve years of age, those only escaping who had no inflammation or oedematous tumour in the throat. Such as recovered, after sweating, had scales peeling off the skin; then adults had a swelling over their body and of their belly, which continued several weeks like leucophlegmatia, and then went off by sweat and urine. This epidemic seems a considerable deviation from their general progress laid down in the scheme of them already mentioned, and is, therefore, particularly noticed in this place.

"8. In 1665, an excessively severe frost, which continued to the end of March, summer temperate; 1666, a very hot dry year, followed by two as wet and cold. In 1665, immediately after the frost, began the plague in London, which killed, according to the least computation, sixty-eight thousand five hundred and ninety-six. Since that time the plague has vanished from London, and all other epidemics seem to have become less malignant, owing to many causes; among which may, perhaps, be a greater use of fresh vegetable food, a less use of fish, an universal use of tea, superior cleanliness in our persons, a greater attention to the poor in times of scarcity, which are now scarcely felt in any extreme degree, and, lastly, the tremendous fire in 1666, since which the streets have been very much widened, and the houses so enlarged, that the same number of inhabitants now occupy above double the space. In 1667 an epidemic fever, with aphthæ, prevailed in Holland, in which acids were useful, but neither bleeding nor purging.

"9. In 1669, the summer intolerably hot, after which the winter was as severely cold and frosty; 1670, a severe frosty winter; the rest of this constitution bad and wet. In 1669 a most fatal fever prevailed, with slimy tongue, sore mouth, &c. in which bleeding was hurtful, but acids and laxatives very beneficial. Sydenham does not mention this fever, nor its return in 1678, although, next to the plague, they were the greatest epidemics in his time; which, together with his

little knowledge of putrid fevers, can only be attributed to his practice lying about the court; whilst Morton, who practised in the city, gives abundant proofs that putrid complaints were as prevalent then as at this time. The same year, in Norway, malignant measles are said to have prevailed, with thrush, which, if mismanaged or neglected, ended in a fatal mortification. In 1675 a coryza, or cough, were prevalent.

"10. In 1678, summer and harvest droughty, hot, and clear; 1679, winter long, severe frost, and intensely cold; 1680 and 1681, summer extremely dry and hot; the next two years rainy. In 1678 the same fever and sore throat prevailed as in 1669. In 1679, after a most deluging October, a catarrh was universal. In 1682, sphacelated tongues and angina maligna prevailed among cattle; in the same year, in Dublin, a fatal petechial fever.

"11. The year 1684 was remarkable for the severest frost remembered at that time, succeeded by a very dry and hot summer, to which 1686 bore a near resemblance: the other years were rainy till 1691. In 1684 spotted fevers, particularly of the miliary kind, were common. This and the following year of 1685 are remarkable for the greatest number of burials; from 1665 to 1714, although 1684 does not contain St. James's, Westminster, and neither 1684 nor 1685 contain St. Ann's, Westminster, nor St. John's, Wapping, parishes, which are inserted in every following bill of mortality, and which then buried above sixteen hundred annually at a medium. In 1688 an epidemic catarrh prevailed all over Europe.

"12. A frosty winter in 1691, and excessively hot and dry summer. The same in 1694, the other years rainy and variable. In 1691 a fatal spotted fever prevailed; in 1693 an universal catarrh; and in 1695 the whooping cough.

"13. Of 1698, an exceedingly hard frost in the winter; the rest of this constitution rather rainy. In October, 1698, began a fatal contagious spotted fever, which spread all over England. Coughs attended most of the diseases in 1703.

"14. The year 1704 was excessively dry, so that the grass was burnt up; this continued until August 15, 1705; the rest of this constitution cold and wet. In 1704 malignant spotted fevers were common. In 1708 coughs and coryzas prevailed every where, so that few escaped.

"15. In 1709, great frost all over Europe, and even in Portugal; 1712, a very frosty winter; the rest of this constitution variable. In 1709 the plague broke out in Dantzick, immediately after the thaw, and killed twenty four thousand five hundred and fifty-three. In 1710 the plague in Copenhagen killed twenty-five thousand. In 1712, sore throats universal in July and August, with dizziness and pains of the limbs, in London.

"16. The year 1714, and the six succeeding years, were all dry, with hot summers. In the winter of 1716 so severe a frost that the Thames was covered with booths; that of 1718 likewise very frosty; the rest to 1731, cold, wet, and variable, except 1723, which was cold and dry; and 1729, which was a cold dry winter, followed by a hot dry summer. In 1720 the plague killed sixty thousand in Marseilles. In 1729 an universal epidemic catarrh prevailed in November.

"17. The year 1731 was a very dry one, which con-

tinued until harvest 1732; summer of 1733 rather dry and pleasant, as was most of 1738; the remainder of this constitution extremely wet. In the beginning of 1733 was an epidemic catarrh; 1737, 1738, and 1739, were all much affected with catarrhal fevers, especially among children.

"18. In 1740 was the severest frosty winter and spring that had happened for three hundred years; 1741, extremely dry hot summer; 1742, a variable, but dry, year; the rest of this constitution wet or variable. In 1740 a malignant petechial fever made great havoc in Bristol, and in Galway in Ireland. In 1741 it reached London, where this and the last year were the most mortal ever known, except when the plague reigned, the burials amounting to sixty two thousand nine hundred and eighty. In 1742 the putrid sore throat broke out. In March, 1744, an epidemic catarrh was universal, and was more fatal than usual.

"19. In 1747, there was an excessively hot dry summer; 1750, a dry year throughout and intensely hot summer; the rest of this constitution moderate, variable, or wet. In 1747, and the succeeding years, the sore throat seemed to acquire new vigour, alarming the inhabitants of these kingdoms very much. In November, 1758, there was an universal epidemic catarrh.

"20. The year 1760 was droughty from June 26 to September 16; the end of that and the following year severely wet, as was the end of 1763 and beginning of 1764; the rest of this constitution moderate. In April and May, 1762, a most epidemic catarrh.

"21. A very dry year, and rather hot summer in 1765, as was the next year, though not quite so much so; the remainder of this constitution moderate years, rather inclining to wet. During this constitution no very remarkable epidemic till the universal catarrh in November, 1775, unless we reckon such, the small pox of the year 1772, which, succeeding a hard winter, were more fatal than they had ever been before in London.

"22. The year 1776 was dry, and 1778 still more so. The winter of 1780 was the most frosty since 1740: yet these deviations from what might be accounted moderate weather were so small as scarcely to deserve notice. In May, 1782, there was a very general epidemic catarrh; and early in 1783 began the constitution which produced the epidemic scarlatina anginosa, which spread very considerably."

See Dr. Wallis's Sydenham.

EPIDE'RMIS, (from *ἐπι*, and *δερμας*, the skin). See CLITORIS.

EPIDE'RMIS, (from *ἐπι*, upon, and *δερμα*, the skin). See CUTICULA.

EPIDE'SMIS, (from *ἐπι*, and *δεω*, to bind). A bandage by which splints, bolsters, &c. are secured.

EPIDI'DYMIS, from *ἐπι*, upon and *διδυμος*, a testicle). The epididymis may be reckoned a testis accessorius, called by Hippocrates, *parastata*. It is a body on the upper part of the testicle, formed of a continuation of the tubes that constitute its body: the continuance of the epididymis upwards forms the vas deferens. See TESTES.

EPIDI'DYMIS DISTE'NSA. See SPERMATOCELE.

EPIDO'SIS, (from *ἐπιιδωμι*, to increase). Preternatural enlargement of the parts.

EPI'DROME, (from *ἐπι*, upon, and *δρεμω*, to run). An afflux of humours, particularly from a ligature.

**EPIGASTRICÆ ARTERIÆ**, (from *epigastrium*). **THE EPIGASTRIC ARTERIES.** The external iliac artery divides into two branches at the ligamentum Poupartii; one of these is the epigastric, which runs to the inside of the rectus abdominis, at whose upper part it communicates with the internal mammary. Dr. Hunter observes, that in the operation for the femoral rupture, we endanger dividing the epigastrica if we cut upwards and outwards; and if upwards and inwards, the spermatic, as the hernial sac lies in the angle between the two.

**EPIGASTRICÆ VEINÆ.** **THE EPIGASTRIC VEINS.** The external iliac veins, a little before their going out of the belly, send off from the inside the epigastric veins, from whence branches run to the neighbouring glands, up the muscoli recti abdominis, and then, advancing, join the mammaria.

**EPIGASTRIUM**, (from *επι, upon, or above, and γαστήρ, the stomach*). The upper fore part of the belly; reaching from the pit of the stomach to an imaginary line above the navel, supposed to be drawn from one extremity of the last of the false ribs to the other. Its sides are called hypochondria, and are covered by the false ribs, betwixt which lies the epigastrium.

**EPIGENEMA**, (from *επιγεναιω, to generate anew*). Sometimes it signifies an adventitious symptom; at others any thing added, as a fur on the tongue.

**EPIGINOMENA**, (from *επιγινομαι, to succeed, or supervene*). Those symptoms which naturally succeed, or may be expected in the progress of a disease (Galen); but Fæsius considers them as accessions of some new affection, which never happened but in stubborn and malignant disease. See *ΕΠΙΦΑΝΟΜΕΝΑ*.

**EPIGLOSSUM**, (from *επι, upon, and γλωσσα, the tongue*; from a less leaf growing above a larger in the shape of a tongue). See *LAURUS ALEXANDRINA*.

**EPIGLOTTIS**, (from *επι, and γλωττις, the aperture of the larynx*). See *ASPERA ARTERIA*.

**EPIGLOTTUM**, (from *επιγλωττις*). An instrument mentioned by Paracelsus for elevating the eye lids, resembling in shape the epiglottis.
